There are other fragments of sculpture from these rock surfaces which might have been referred to, but it will, for the present purpose, be unnecessary, for those who have carefully looked at the rudest of the Romanesque work will know how much has been done by men to whose works the term high art has never yet been for a moment applied, and to do so would be considered, in the present low state of art knowledge, as simply ridiculous; yet there can be no doubt that very many of those have left behind them specimens of work, in the very rudest and roughest manner, which, so far from being equalled in more learned days and by more refined men, have not been approached in artistic, mental, and manual power. It is a very long distance from central north Africa to the new Cattle Market, and some time has elapsed since the centuries B.C. and the present highly civilised and most enlightened century, but has any gentle or simple reader ever seen in process of execution, or in a completed state, any one or more specimens of the *cattle drawing* to be found occasionally going on there, *i.e.*, in the new Cattle Market, when a very favourite bull, or very fine ox, comes to market, and an order is given by some art-loving farmer or salesman for his portrait in oil colours? We ask has anybody with an eye ever seen such a production? if not, he has something yet to see and learn. If he has seen one I am certain he cannot have forgotten it. We simply ask him most respectfully to mentally compare the results of the present advanced system of art education, as visible in it, and the past rude plan of doing things, when there certainly were no art schools or royal academies in existence either to help or to hinder. We are, or at least ought to be, never too old to learn. Or, to pursue the thought a little further, will anyone compare the portrait of some noble lord's "favourite breeding bull," enclosed in a paddock, with a whisp of straw in his mouth, and exhibited on the walls of the Royal Academy, and in a good place too, with the Phidian bulls or the African rock work! And yet, be it recollected that the modern London Cattle Market can exhibit to the eye of the artist workman animal life as fine and as worthy of living and moving portraiture as anything Phidias ever saw. But we are educated and he was not!

But the special lesson to be learnt from this, that is, if we will try to learn it, is, as hinted in my former paper, that the real secret of power in art in the production of a result is to be sought, not in the imaginative powers of the executive artist, but in nature and natural forms and accidental occurrences, and that to get at this, in whatever material it be sought for, *the hand of the individual artist and workman is needed*. The terms high and low art have, in truth, no such meaning as is now attributed to them by our schools and academies; thus degrading one set of artists while another set is almost deified, for we here see the greatest of sculptors employing himself in the simple copying of the mere natural forms and actions of common cattle, at the same time that his capacity and genius were such as to give him power over the human form in its most graceful postures and movements, and that in a way which has never been in any age of the world or anywhere equalled. Perhaps there is no other such instructive lesson as this in the whole history of art practice. Why, we may ask, are there no such sculptors as Phidias nowadays? what had he, so far, at least, as animal life is concerned, *more* than the modern sculptor of to-day to work upon and with? And then, too, another question starts up here of great significance. Would Phidias be considered in these days, and by our modern authorities, or by Mr. Ruskin, as an artist of *high* art powers and standing, had he sculptured *nothing but cattle?* Supposing it could be proved that none of the "figures" were by him, but only the victims of sacrifice, would such work, magnificent as it undoubtedly is, entitle the man who executed it to the rank of an artist producing *high* art? No, certainly not, most people will doubtless say. But why not? for it is to the very utmost as difficult to draw and paint or chisel a bull as a man—in some respects more difficult, for is not that most mysterious of all things, the life in them, to be made visible and evident in both? The mere *form* is as hard to do in the one as in the other, and as easy, if it can be done at all. But, unhappily, we have no means of judging of all this. There is, as I before said, no trial or student's work anywhere visible; no Academician condescends to draw or carve animal life in its simplicity or in its native state of living action. Landseer draws animals, deer, and dogs, but they are all harmless domesticated brutes that will quietly stand for their portraits, or lie down on hearthrugs by the hour; in short, civilised creatures are nearly or quite useless for artistic purposes, for all the life natural to them seems to be gone, and to have been fairly groomed out of them, leaving little else but their skins. C. B. A.

A MEDIÆVAL ARTIST'S SKETCH BOOK.

THERE are in MSS. in the British Museum some rare and very beautiful architectural backgrounds, in rich colours, as of Paris, with Notre Dame, in Harl. MS. 4,379; an illustration of a scene in Froissart; and in the royal MS. XVI. F. 2, containing the poems of Charles, Duke of Orleans, is a pictorial view of London from the Tower, with an interesting portraiture of old London Bridge and its exquisite apsidal chapel at the south or Surrey side. But these are not so curious or valuable as the unique illustrations found in the margins of a copy of Geoffrey of Monmouth, made in the fourteenth century (Royal MS. XIII. A. 3.), which I lay before your readers as eminently suggestive to the modern architect, and affording, probably, the only known instance of an English mediæval artist's sketch book, although not so strictly professional as that of Willars de Honecourt. I owe the knowledge of their existence to the kindness of Mr. Frederick Thompson, and with special permission made careful traceries of them.

The engraving of a central lantern with a leaded spirelet in the Monasticon, taken from a Cottonian MS., and representing St. Benet's, Hulme, offers a distant resemblance to some of the elevations of similar structures; but the latter are peculiar in being raised on a lower stage, as if, in many instances, doubled. There is apparently a lingering recollection of foreign taste discernible, as though the unknown artist had been a traveller beyond seas. Perhaps the seals of the period and those of an earlier date, as in the instance of Battle Abbey, make the nearest approach of similarity to these drawings, which are sketched in pencil delicately, and with a fine, point, and afterwards have been tinted by a brownish-lilac tint of colour. The draughtsman, as far as we can judge, in most cases produces buildings no longer extant; but again there are instances in which we can trace a likeness to churches either still in being, familiar to us by description, or changed by subsequent additions. The proportions are graceful, the character of style and tracery is distinct, and it requires but the practised hand and eye of the modern architect to recognise germs of beauty and suggestions of fine forms grouping, and outline, from which his own genius and knowledge would soon construct buildings capable of reproduction and adding fresh reputation to his name. Simplicity and dignity, quiet force and grandeur, are blended; there is no frittering of ornament, no straining after exotic decoration or fanciful and capricious novelties, which now pass current for originality; and in all there is a genuine hearty English feeling perceptible in every line. The castles and houses in many cases I have omitted, as they only confused the main features of the central object of interest, and, if introduced, must necessarily have crowded out some of the drawings now comprehended in a single page, whilst those actually given present a very fair sample of the rest.

I proceed to notice the designs in detail.

1. Canterbury.—The western elevation of a town church, with a three-light Decorated window. In the spandrels are quatrefoils, on

either side is a small turret with a leaded spirelet, which terminates in a cross. Below the window is a double doorway, with a spandrel included under a comprising arch. The aisles have lean-to roofs, with a two-light window in each face having a circle in the head; at the angle is a turret pinnacled, with arcading in the upper portion, and bold mouldings at the base; above the great west window rises the arcaded stage of a tower which has angle-pinnacles, and a central spire of moderate height.

2. Leicester.—A minster. The west front presents a gable, with three round-headed windows below it, arranged pyramidally, two and one; it is flanked by tall turrets, with a single window in each face, and terminating in a thin spirelet. The transept represents two round-headed windows in the clerestory of each arm, and angle turrets. Over the crossing rises a small low tower, in two stages, crowned with a little spire.

3. A design for a gable, reminding the reader of Exeter Cathedral. The sides are crocketted, and the finial takes the form of a *fleur-de-lis*; in front of it runs a battlement with trefoils in the merlons. Below this is a beautiful canopy, crocketted and richly foliated, having a delicate quatrefoil or rose on each side. A triangular shield, like a shortened "heater," *semée* of crosses, and surmounted by a ducal coronet, completes the design.

4. Colchester.—A noble west front with angle towers in two stories and tall spires projecting beyond the aisles, as at Wells; five doorways, beautiful canopied four-light windows to the aisles, and a grand western window with rich tracery of quatrefoils and circles in the head. The crocketted gable contains a rich trefoiled window; the central tower has trefoiled windows in the lower stage, which has a leaded roof, above which, and from an arcaded base, rises a low spire.

5. A western tower, with a spire in two stages, flanked with lean-to aisles.

6. London.—The superb canopied Decorated window of four lights, flanked with turrets, the beautiful tower in two stages, each containing a pair of windows, and graceful spire, no doubt represent old St. Paul's in its integrity before Inigo Jones added his monstrous addition at the west end. Amongst a forest of spires, we may recognise St. Mary Overye, with its steeple now showing only as a tower, and the west front of Westminster Abbey, possibly an ideal, with arcaded turrets and spirelets, and two beautiful Decorated windows; and, beyond, a low central tower and flèche, which would, if carried out, indeed give an outer glory to a building deformed by the detestable additions of Wren.

6*. A west front, with gabled ends to the aisles, and turrets, to be compared with No. 2.

7. Winchester.—A design enlarged from No. 4, with the addition of a fine two-light of remarkable design, having a pierced lozenge-shaped transom.

8. A corbel head, probably of Edward II.

9. A two-storied west front, with round-headed windows, angle-turrets, battlements, and a broad central spire; the lower story is arcaded.

10. Gloucester.—1. A west front, with a west window having interlacing tracery, arcaded angle turrets with very thin spires, and a central tower, like that of Winchester Cathedral, carrying a very lofty spire flanked by pinnacles. 2. A very remarkable elevation—a tall gable, with its cross; above, a beautiful triplet without a comprising arch, of admirable proportions, and flanked by two fine towers with angle-turrets (like St. Nicholas, Ghent), lofty windows, and low spirelets. 3. A gable with angle-turrets, and a broad band of quatrefoils and a central rose; behind it is a central tower and flèche.

11. Caerleon.—A west front, somewhat similar to 4 and 7, combining features in each. Above the window rises the upper part of an arcaded tower, which has a broad band of quatrefoils, angle-turrets, and low spire. The portal is double, and each doorway is cinquefoiled. The windows of the aisles are of two lights, canopied, and with foliated tracery in the head. The angle turrets have windows in stages.

12. A beautiful wayside cross. A shaft raised on three steps, very delicate in design, and apparently carrying a cross of metal, most graceful and simple, and perhaps jewelled.

13. York.—A west front, with a triplet within a comprising arch. A gable and flanking turrets, a central steeple, arcaded, with spire-lights of diamond shape, complete the design. Besides these is a range of noble canopied two-light windows, a tall tower with a flying buttress, foliated underneath; steeples and turrets fill the background.

14. City of Rome.—1. A superb tower, with lateral turrets and pinnacles, and windows in three stages, above a central door, full of character and dignity. 2. A magnificent west front, with lateral towers projecting beyond the aisles, and, like them, filled with two-light windows. Five cinquefoiled portals admit to the interior; the central bay, like the aisle, is flanked by pinnacled turrets, and below the steep gable there is a grand window in two stages. The central tower is battlemented. The whole composition is full of inventive power.

I can only hope, in conclusion, that these drawings may recommend themselves to architects in general, and that some may be induced to vary the wearisome sameness of modern churches—wearisome from eccentricity and trick, or from the tameness of feeble imitation—by hints gathered from the tracing of a hand that has lain still for five hundred years. There are in this MS. some good heraldic designs and some vigorous battle scenes.

MACKENZIE E. C. WALCOTT, B.D., F.S.A.

ARCHITECTURAL FOLIAGE.*

THIS is a work published in parts at five shillings a part, containing six plates. The plates are lithographed. Now lithography has done a good deal for art; but, in the opinion of many well qualified to speak *ex cathedra*, the old school of copper-plate engraving did, in its day, even more. The lithograph lends itself with what is called "fatal facility" to careless design, from the ease with which, by a *tour de main*, gross faults may be glossed over. The work before us has many faults, the principal of which is the absence of truth and earnestness. In a lithographed representation of an architectural object, as in a woodcut, some endeavour should be made to convey to the spectator a fair idea of the subject. Black outlines and forced shadows are but poor substitutes for delicate forms and truthful treatment. A book is a book, and should not be put forth without good reason, and, at all events, should be heralded in becoming terms. When we find such remarks as are contained in the circular accompanying the work we must be permitted to exercise our discretion and estimate its value by our own lights. "The above work will be found of great service to architects, sculptors, carvers, and others, in furnishing them with a series of choice examples for architectural purposes." To all this we cannot subscribe. The designs are too realistic, are forced in the representation, and deficient in vigour. The foxglove, the fern, the convolvulus, the geranium, the passion-flower, and the snapdragon, are depicted in various forms. In 1865, Mr. James K. Colling, F.R.I.B.A., published a work on "Art Foliage for Sculpture and Decoration," nearly all of his designs having been previously and by special arrangement illustrated in the BUILDING NEWS. The work before us is no improvement on that of Mr. Colling. Mr. Robinson also publishes a series of designs for "carved panels suitable for headstones, crosses, tombs, &c." The circular accompanying this work states that "the designs in the above work are very chaste and beautiful, being adapted from natural foliage, with scrolls, passages of Scripture, monograms, &c., and are designed to supersede the many tasteless broken columns, urns, weeping willows, &c., which so frequently disfigure an otherwise passable memorial. In publishing this work at a low price, Mr. Robinson hopes the designs may be generally adopted, and thus make another great improvement in the memorials placed in our cemeteries and churchyards." In the whole range of art nothing is more difficult of production than a suitable memorial. From Captain Noah down to Captain Cook, from Prince Lee Boo to the Prince Consort, memorials have been a failure, and we do not find, even in this work, any indication of "another great improvement." On the contrary, the memorial designs are much below the average, and the terms in which they are introduced to the public are not calculated to disarm criticism.

* "Architectural Foliage adapted from Nature." By JOSEPH BARLOW ROBINSON. London: Bemrose and Sons, 21, Paternoster-row.

THE TANK SYSTEM OF SEWAGE.

THE *Engineer*, in an article on this question, says, the local board of Hastings have recently completed works for discharging their town sewage into the sea, which carries it away from the town. There are two or three points in connection with this scheme to be particularly considered. One is whether experience—for nothing else will decide the question conclusively—will demonstrate that by these means the sewage, with all its noxious and disagreeable accompaniments, will be really got rid of; the other embraces the policy, economical and otherwise, of allowing so enormous a waste to be made of valuable manure; and the third has reference to the ultimate disposal of the solid residue which accumulates on the shore. We have already expressed our opinion, supported by facts, respecting the mistake of converting the ocean into a cesspool; but, upon the other hand, it may be four or five years before any serious annoyance results from the error, and certainly anything was to be preferred to the state of drainage existing at the fashionable watering-place in question. It appears that some years ago nearly £20,000 were expended in what was called the drainage of Hastings, which consisted, as is usual upon all coast towns, in running the sewage by a number of outlets into the sea. These pipes and culverts discharged at all times of the tide, sometimes flowing pretty full, at others merely dribbling, to the great disgust and annoyance of bathers, who, however, continued their marine ablutions notwithstanding. It was not until the appearance of fever in the town that the ventilation of the sewers was attended to, but, although this in some measure mitigated the evil, it did not remove it, and the authorities determined to adopt a totally different principle of drainage. According to the present system all the old outlets are abolished, new main and branch sewers constructed which convey the sewage into a large tank holding about a million and a half gallons. It is here stored up until the proper turn of the tide takes place, which sweeps it away, or, at least, a large portion of it, east of the town. The tank is supposed to be filled and emptied once in every twenty-four hours, or nearly so. Assuming this to be practically the case, and putting the value of the sewage at the lowest figure, the sea at Hastings engulfs annually £10,000, and to accomplish this suicidal result the board has spent £30,000.

Having investigated the fallacy of the principle, and demonstrated the reckless disregard of the true value of sewage and its proper utilisation and application to land, evinced by the scheme in question, let us now direct attention to the disposal of the solid residue in the tank. The hope of converting this into a marketable manure, and inducing agriculturists to purchase it, is the wildest idea of all. There is, of course, nothing new in the tank system of sewage. It has been used at Birmingham, Coventry, Uxbridge, Leicester, and numerous other towns, partially for the purposes of storage, and also for obtaining a residue from which to manufacture a saleable artificial manure. Every instance where it has been attempted to sell artificially manufactured

sewage manure has resulted in a miserable failure. It was calculated at one place that £4 per ton would be given by farmers for the manure, and the price obtained with a great deal of difficulty was 4s. After an elaborate process of deodorisation and evaporation scarcely sixpence per ton could be realised at Birmingham for the solid residue, which, it is needless to observe, would not pay for the cartage of it. In face of these facts, as clear as unquestionable, it is not easy to comprehend upon what foundation the expectations of those can rest who hope to achieve a result that both theory and practice have proved to be impracticable. Theory has demonstrated that the various precipitating chemical re-agents hitherto employed do not fix the ammonia, the most valuable constituent in sewage for agricultural purposes; and even if they did, practice has shown that the compound cannot be disposed of at a price that will even repay the cost of production, much less yield any remunerative return. Farmers and agriculturists, whatever faith they may put in guano, superphosphates, and other artificial manures, have none in sewage compounds, and will hardly cart it away when they may do so gratis. We must not be supposed to assert that no chemical means exist by which a manure possessing fertilising ingredients could be manufactured from the solids extracted out of the fluid sewage; but we maintain that, in the first place, the process is tedious; and that, secondly, the sale of the compound would never repay the cost of its production, thus proving every such scheme, commercially speaking, a failure. At the same time no process of precipitation or artificial manufacture will produce a manure at all approaching in powers of fertilisation to the unadulterated sewage, which is allowed to irrigate the land in the manner so conclusively successful at Barking and Croydon. There is but one solution to the great national sewage problem, and although it will take years yet before the truth is universally acknowledged and recognised, nevertheless it will be finally established. All schemes of deodorisation and disinfection, all projects for getting rid of our town refuse into rivers and seas, will sooner or later prove so many mistakes; and those who have committed themselves to such undertakings will discover the fallacy of their proceedings. The proper disposal of sewage is the utilisation and application of it to the land, that it may return to the soil that which was taken from it, fertilise the ground that is barren, and refertilise that which is exhausted. Any other plan of disposing of it is simply an evasion of responsibility, a dereliction of duty, and a flagrant and unjustifiable waste of that which no money can replace.

WOODS USED IN CABINET-MAKING.

MR. THOMAS PATERSON was one of the working men who visited the Paris Exhibition last year, and ably reported on what he saw there. His report is one of the twelve which compose the little work under the title of "Modern Industries," issued under the auspices of the Paris Excursion Committee. In looking through the magnificent collections of woods from Brazil, Canada, and New South Wales, and the smaller but not less interesting exhibits of Algiers, Natal, Guinea, &c., it is impossible not to be struck, says Mr. Paterson, with the small number of these woods which are in actual use in the manufacture of furniture. Some of the woods are shown to be of large size, and are exceedingly beautiful in colour and figure, and many of them would contrast admirably with some of those at present in use.

There was a contribution to the Exposition of specimens of timber, collected by the late Captain Fowke, in which several hundreds of different kinds of wood are arranged in a kind of revolving screen. Each specimen is labelled with its specific gravity, and the amount of weight necessary to break it. Each piece was of the same size—viz., 2in. square, and has been actually broken by the weight marked on it, thus giving anyone accustomed to work in wood a very good idea of the use it may be put to. Collections of this kind would be of the greatest use. They might be accompanied with a book composed of leaves of the woods, prepared and polished, to show their texture and colour, with labels giving the average size of which boards could be cut, the average price, and the market, &c. At present neither artist nor workman is aware of the resources which are at their disposal, and much meretricious ornament would be avoided if this mine of decorative riches were fully explored. In the French Colonies department there were some articles of furniture which have been made from the woods of Cayenne, cut by the convicts sent to that settlement.

That a wide and systematic acquaintance with the resources of any country is the first requisite to the development of its trade may be considered an obvious truism; yet in this country, eminently trading and manufacturing, and dependent for its greatness upon the growth of its trade and manufactures, no means are taken to make the traders and workers acquainted with the materials which are being wasted in our vast colonies, but which, if known, would be sources of wealth which we can scarcely over-estimate. The staghorn sumac may be mentioned as an example of a very finely veined wood, which seems to be plentiful, and which, though it does not grow to any great size, would be useful in manufacture. The butternut, a kind of walnut wood, grows to a large size, and seems to be very cheap. The kauru (or New Zealand pine), also, as a wood to veneer upon, would, I think, be of the greatest value; as well as the heron pine (which is sufficiently handsome to be used without any veneers), the red beech, and many others.

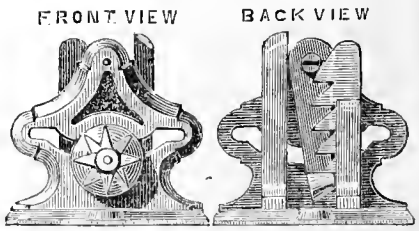
As a new application, or, rather, the extension of an old process in the treatment of wood, the chairs and settees in the Austrian department, made by bending long slips, may be instanced. Some of these chairs were exhibited in 1862. The manufacture has, however, greatly improved since that time. One chair in the Exposition (purchased by the Prince of Wales) was all that could be wished, both as regards strength and beauty. Though no one would wish to see this system of bending wood applied to all articles of furniture so exclusively as it is applied in the manufacture of these chairs, yet the capabilities of the process are well shown, and much might be learned from them. I noticed a method of producing a very good kind of decoration on polished surfaces of wood by stamping with what is called by chasers a mutt tool, which produces a slightly roughened but regular surface, the pattern being left polished. I observed, also, in passing round the Historical Gallery, a mode of decoration which had an extremely good effect. This was an application of tortoiseshell. The under surface or side applied to the piece of furniture had been polished and gilded, the outside surface of the shell being then carefully smoothed and polished, the gold showing through the semi-transparent shell, and giving all its markings, while the shell protected the gilding, so that, though it had been made for more than twenty years, it was still beautiful and effective. It seems to me much to be regretted that some method cannot be devised which would place all such methods of decoration so completely before all our workmen and designers that they might have them, so to speak, at their fingerends.

CURIOUS MONUMENTS IN BENGAL.

THERE exists, within 300 miles of the British capital of India, a tribe of semi-savages, who habitually erect dolmens, menhirs, cysts, and cromlechs, almost as gigantic in their proportions, and very similar in appearance and construction, to the so-called Druidical remains of Western Europe: and, what is still more curious, though described and figured nearly a quarter of a century ago by Colonel Yule, the eminent Oriental geographer, except by Sir J. Lubbock, they are scarcely alluded to in the modern literature of prehistoric monuments. In the Bengal *Asiatic Journal* for 1844 you will find Colonel Yule's description of the Khasia people of East Bengal, an Indo-Chinese race. Dr. Thomson and I dwelt for some months among the Khasia people, now eighteen years ago, and found Colonel Yule's account correct in all particulars. The undulatory eminences of the country, some 4,000ft. to 6,000ft. above the level of the sea, are dotted with groups of huge unpolished squared pillars and tabular slabs, supported on three or four rude piers. In one spot, buried in a sand grove, we found a nearly complete circle of menhirs, the tallest of which was 30ft. out of the ground, 6ft. broad, and 2ft. 8in. thick; and in front of each was a dolmen or cromlech of proportionately gigantic pieces of rock, while the largest slab hitherto measured is 32ft. high, 15ft. broad, and 2ft. thick. Several that we saw had been very recently erected, and we were informed that every year some are put up, but not in the rainy season, which we spent in the country. The method of removing the blocks is by cutting grooves, along which fires are lighted, and into which, when heated, cold water is run, which causes the rock to fissure along the groove; the lever and rope are the only mechanical aids used in transporting and erecting the blocks. The objects of their erection are various—sepulture, marking spots where public events had occurred, &c. It is a curious fact that the Khasian word for a stone, "man," as commonly occurs in the names of their villages and places, as that of man, maen, and men does in those of Brittany, Wales, Cornwall, &c.; thus Mansmai signifies in Khasia the stone of oath; Mamloo, the stone of salt; Manflong, the grassy stone, &c., just as in Wales Penmaen Mawr signifies the hill of the big stone, and in Brittany a menhyr is a standing stone, and a dolmen a table-stone, &c.—*From Dr. Hooker's Presidential Address at the British Association Meeting.*

TEMPLAR'S PATENT SASH FASTENER.

IT is a general subject of complaint that the ordinary fastenings of our windows are easily opened from the outside by means of a knife, and that if it is desired to have the window partially open—for the sake of ventilation for instance—it cannot be secured; and so we have to run the



risk attendant upon an open window, or forego the benefits of ventilation and pure air. The little contrivance illustrated by the accompanying woodcut is intended to obviate all these inconveniences, and we believe does so in a most

efficient manner. Its action will, we think, be readily understood by a reference to the engraving. It is self fastening: a servant closing the window fastens it at the same time without any extra effort or thought. The window can be partially opened and still secured by means of the toothed catch, and the overlapping of the bases of the two parts effectually prevents the introduction of a knife. Moreover, the dropping of the top sash does not interfere with the action of this fastener, as it does with that of the ordinary ones, and it is claimed for it that it effectually prevents rattling by the wind.

THEATRE BUILDING.

CASE UNDER THE METROPOLITAN BUILDING ACT.

AT the Marylebone Police-court, on Thursday week, Mr. D'Eyncourt was engaged for several hours in hearing a case of the most difficult and important character, the decision affecting no less than three theatres now erecting in London. The case was also of public interest, inasmuch as it concerned the safety of the audiences in theatres during the panic that would result in case of a sudden outbreak of fire. The Marylebone Theatre, in New Church-street, Edgware-road, is now undergoing alterations prior to its being shortly reopened to the public as the "Royal Alfred" Theatre. Mr. Alexander Peebles, the district surveyor of the northern division of Marylebone, acting under the provisions of the Metropolitan Building Act, visited the premises, and noticing that the builder, Mr. Samuel Simpson, of Tottenham Court-road, did not carry out the works in accordance with the rules laid

down in the Act, he gave him notice of the alterations and additions which he required to be done. The builder took no notice of this communication, nor did he appeal to the Metropolitan Board, then sitting, but, according to the district surveyor's evidence, he proceeded with the work with extra speed. Under these circumstances, the district surveyor took out a summons against the builder, under the Metropolitan Building Act, for that he "did do certain things contrary to certain rules of the said Act, to wit, did construct the floors of corridors leading to the boxes upon the first gallery, and also the floor at back of side gallery, with combustible materials, and did omit to do certain things required to be done by the said Act, to wit, to construct the side floor with stone or other fireproof material, and carried by supports of a fireproof material, as required by section 22." After a long discussion as to what was meant by the term "corridor," during which references were made to Johnson's, the "Imperial," and other dictionaries on the subject, the case was simplified by the defendant stating that he had not obeyed the notice from the district surveyor for several reasons, among which were the following:—1. The theatre was not essentially different from what it had been before the alteration, except that new material was used, the old having become so rotten that it was unlikely that the Lord Chamberlain would re-license the theatre unless it were removed. The interior arrangements of the former theatre having been approved by the Chamberlain, all that was necessary was to get the Chamberlain's license again.—[In cross-examination the builder stated that the stage had been shortened, and the auditorium thereby enlarged, holding, under the new arrangement, 200 more persons. The magistrate said he was strongly of opinion that the Lord Chamberlain's license did not apply to the question as to the materials to be used in the construction of a theatre. Defendant said it did; for instance, if he deposited plans approved of by the district surveyor, but which did not meet with the approval of the Chamberlain, he (the builder) would have to alter those plans before he could get the license. Mr. D'Eyncourt asked to be shown any section which exempted theatres from the operations of the Metropolitan Building Act. Plaintiff said there was no exemption for theatres.]—2. Defendant said he had built the Queen's and Holborn Theatres, and there were surveyors in those districts, but they had not objected to the mode in which those buildings had been constructed, though it was precisely the same as in the present case. He was also building the Gaiety Theatre, and no difficulty was made by the district surveyor there.—[Mr. D'Eyncourt observed one object contemplated by the act was the safety of the public during fire, and to say that Mr. Peebles ought not to take action because two other district surveyors had not thought proper to do so was no proof that Mr. Peebles was wrong.]—3. The defendant said the plans were approved of by the official at the Metropolitan Board who acted on behalf of the superintending architect.—[It was contended by the plaintiff that this was not the approval of the Metropolitan Board.]—Mr. D'Eyncourt, in giving his decision, said that he considered this to be a new building, and came under the operations of the Building Act. He was, therefore, bound to say that he believed the plaintiff had made out his case, and the necessary alterations must be made in accordance with the district surveyor's notice.—[As the defendant seemed dissatisfied with the decision, the magistrate intimated his intention on that day week (yesterday) to give fully his reasons for the decision arrived at.]

UTILISATION OF STORM WATERS IN FRANCE.

THE great point of difference between the sewerage of London and that of Paris is that the sewers in the latter city do not convey any solid matter, but their contents consist of the rainfall and storm waters, the refuse of street drainage, of the urinals, and the waste waters from houses and industrial premises. Compared with the perfect system of our metropolitan drainage, that of Paris is very incomplete, and by no means up to what we should regard as a proper standard for so fine a city. The important question of purifying the contents of their sewers, and utilising them as a manure, has for some time engaged the attention of many of the *savants* and engineers in Paris. During the last two years the municipal authorities have granted divers sums for the purpose of defraying the cost of some reliable experiments in connection with the subject. A double object was to be obtained by the execution of any project that embraced the desired end. One was to put an end to the evil resulting from the discharge into the Seine of the contents of the sewers, and the other to utilise them when intercepted, and distribute them over land to produce a fertilising effect as a valuable manure. Not only would the advantage, viewed in this light, be of a twofold nature, but the public health and agricultural prosperity would be likewise benefited by it. Bearing in mind what had been done in England with respect to utilisation of sewage, and the great value of the irrigation system carried on in Italy and Spain, the Parisians commenced their operations upon a single piece of ground near to the discharging main sewer at Asnières. In order to give the matter a perfectly fair trial, it was determined to separate the mode of proceeding into two distinct sections; in the one, the water was treated with chemical reagents, and thus partially purified; in the other, the irrigation was carried on direct from the discharging outlet, without any preliminary purification. The latter plan will unquestionably be found the preferable, as all the expense and uncertainty of the clarifying process will be saved. At the same time, it is frequently necessary to provide settling tanks, for the water to deposit some of the heavier particles held in solution before it is permitted to flow over the land.

The chemical process adopted at Asnières consists in the treatment of the sewer water with sulphate of alumina, fourteen grains per gallon being sufficient to precipitate the suspended ingredients, and effect the purification of the liquid. The purifying tanks have been for some time in regular operation, and their success has been most satisfactory. Financially the results have been as follows:—The manure sells at 15s. the ton, and the cost of its production varies from one-fifth to one-third. Several acres have been planted with Indian corn and beet-root, and have yielded excellent crops. Possibly some of our readers may recollect seeing at the Champ de Mars some very fine specimens of pumpions, remarkable both for their size and weight. These were grown at Clichy, upon irrigated land, and the system adopted was that of open carriers, very similar to what is termed among us "the pane and gutter system." Experiment has demonstrated that at Clichy the quantity absorbed by the soil was at the rate of 7,000 gallons per acre per diem, for a continuous period of twenty-one days, which is equivalent to a rainfall of 1½in. in the twenty-four hours. The merit of having successfully carried out these irrigating sewage works is due to a French engineer, M. Mille, and the municipal authorities are so well satisfied with the results of his exertions that they have granted a large sum of money for the further development of similar works upon a more extended scale. These are to be carried out upon the plans of Gennevilliers, where tanks, reservoirs, and all necessary appliances and machinery will be provided for the purpose. It will not, therefore, be surprising if the people of Paris actually utilise their waste and refuse water before ourselves.—*Mechanics' Magazine.*

SUGGESTIONS FOR THE CONSTRUCTION OF MUSEUMS.

DR. HOOKER'S inaugural address at the meeting of the British Association at Norwich contained some excellent remarks under this head. He said:—Much of the utility of museums depends on two conditions often strangely overlooked—their situation and their lighting and interior arrangements. The provincial museum is too often huddled away, almost out of sight, in a dark, crowded, and dirty thoroughfare. Such localities are frequented by the townspeople only when on business, and when they consequently have no time for sight seeing. In the evening, or on holidays, when they could visit the museum, they naturally prefer the outskirts of the town to its centre. The museum should be in an open grassed square or park, planted with trees, in or on the outskirts of the town, a main object being to secure cleanliness, a cheerful aspect, and space for extension. Now vegetation is the best interceptor of dust, which is injurious to the specimen as well as unsightly, while a cheerful aspect and grass and trees will attract visitors, and especially families and schools. If the external accessories of provincial museums are bad, the internal are often worse; the rooms are usually lighted by windows on one side only, so that the cases between the walls are dark, and those opposite the windows reflect the light when viewed obliquely, and when viewed in front the visitor stands in his own light. For provincial museums, when space is an object, there is no better plan than rectangular long rooms, with opposite windows on each side, and buttress cases projecting into the room between each pair of windows. This arrangement combines economy of space with perfect illumination, and affords facilities for classification. Upon this plan the large museum at Kew is built, where the three principal rooms are 70ft. long by 25ft. wide, and each accommodates 1,000 square feet of admirably lighted cases, 6,700ft. of wall room for pictures and for portraits of naturalists, besides two fireplaces, four entrances, and a well staircase 11ft. each way. A circular building with cases radiating from the wall between the windows, would probably be the best arrangement of all. A light spiral staircase in the centre would lead to the upper stories. Two or more of the bays might be converted into private rooms without disturbing the symmetry of the interior or interception the lighting of the cases. The proportions of the basement and first-floor might be such as to admit of additional stories being added, and the roof be so constructed as to be removable without difficulty when an additional story was required; furthermore, rectangular galleries might be built, radiating from the central building, and lighted by opposite windows with buttress cases between each pair of windows.

NEW THEATRE, CROYDON.

THIS building, just opened, comprises a market and hotel, in addition to the theatre, and stands on the site of the old Lecture Hall. The market is open to the front, and well ventilated. The central entrance opens to a wide corridor, leading to the gallery and pit entrance to the theatre, and, on the right, to the Royal Hotel. On the extreme right, past the hotel, is the box office, up a broad flight of stairs. The large space above the ground floor in front has been made into a spacious assembly room. The theatre proper is 54ft. deep by 100ft. wide, the proscenium being almost midway between the walls. The stage is so constructed that when the theatre is required for equestrian performances it may be entirely removed. In addition to the pit and gallery the auditorium comprises fifteen private boxes, 100 box seats, and fifty balcony or dress-circle seats. The front of the balcony tier is rather a novelty, rising but half the usual height. The decorations, which have been executed by Mr. Dillon, from designs by the architect, are Greek. The theatre has been built by Mr. Hutchinson, from the designs and under the superintendence of Mr. T. T. Smith, Bloomsbury-square, the architect of the Holborn Amphitheatre.

COMPETITIONS.

THE trustees for the erection of a new Wesleyan chapel and schools at Burton-on-Trent have selected the designs of Mr. Edward Holmes. The buildings will be erected at the corner of Station and Union-streets, and will cost about £4,000. The designs were submitted in a limited competition.

The commissioners for the erection of the Abergavenny townhall and markets met on Friday last, and finally decided to give the first premium, of £50, to Messrs. Wilson and Willcox, of Bath, the second, £20, to Mr. Haddon, of Hertford, and the third, £10, to the local man, Mr. Neville. There were sixteen competitors, but the commissioners were almost unanimous in finally declaring in favour of the successful competitors. It was a most fair competition, and future committees will do well to emulate the example of the commissioners, each one of whom was furnished with a tabular paper upon which were arranged the various requirements of the particulars of the competition, and as each competitor fulfilled or failed in the particular requirements under consideration was accorded or not a mark against his name. Although the commissioners worked hard at the plans considerable time was thus occupied before any decision was arrived at. Messrs. Wilson and Willcox are entrusted with the contract. Plans and specifications of the work will be commenced at once.

EARLY CLASSIC ORNAMENT.

IN the present day Classic architecture in this country carries very little enthusiasm with it. It is cold and spiritless, and provided it is "according to Chambers," both the architect and his master, the public, are satisfied. Why should the most perfect architecture be dragged through so narrow a channel? What would Gothic architecture become if sketching and measuring were almost ignored, and Pugin taken as an infallible standard? I am confident that Classic architecture can never be great unless we measure, draw, and think for ourselves among the ancient examples. The early Italian artists could have only obtained their knowledge by those means, and why should not we have recourse to the same expedient, and go to the fountain head at once?

I have selected a few examples of early ornament to show that Classic art is not always the tame workmanship it is represented to be. Nos. 1 and 3 of the lithographic illustration are from an ivory-cased box of Græco-Egyptian work in the British Museum. The subjects are vigorously incised, and filled in with red, green, and black cement. There is an air of quaintness about the figures which one does not very often find in the works of those stern old artists. Nos. 2, 5, and 7, drawn principally from examples in the Louvre, are Egyptian renderings of the lotus flower in its various stages of growth, from the incipient bud to the full-blown flower.

The lotus is constantly repeated in Egyptian architecture and decoration, drawn on fixed conventional principles, but one would not identify it by its natural type. No. 6 is a rather unusual hieroglyphic, taken from a black granite sarcophagus preserved in the British Museum. It is a cross form, with palm-like foliage depending from it.

A cross, very similar to that used in early Gothic decoration, may be found in Egyptian, Rhodian, Etruscan, and other work executed long before the Christian era. No. 4 is a very spirited sprig of foliage, from an Etruscan vase in the British Museum. The artists of this per od were so facile with the brush that nothing short of a careful tracing will represent the studied freedom of their touch.

O. W. D.

THE PRESERVATION OF COMMONS.

CASES are now pending in our courts of law upon which the future of our commons and open spaces depends. Sir Thomas Maryon Wilson, Earl Spencer, Lord Brownlow, and others are contesting, as lords of manors, the claims of the public. Hampstead Heath, Wimbledon and Berkhampstead Commons are all representative cases. Some two years ago Lord Brownlow had a large portion of Berkhampstead Common enclosed by a substantial and somewhat costly railing. Mr. Augustus Smith, a landed proprietor with extensive common rights, deemed this an illegal proceeding, so he determined to "return to an old constitutional form." A special train, filled with some hundreds of labourers, started from London by night, and arriving at Berkhampstead, uprooted the railings in a few hours. This proceeding, of course, was the subject of much comment; but to this day the railings have never been restored, and the portion of the common once enclosed is now as open as it has been from time immemorial. Earl Spencer's proposal to convert a portion of Wimbledon Common into a park for presentation to the public was stoutly resisted, for, argued the public, they could not be presented with what was already theirs. That portion of the scheme which provided for "the outlying parts of the common" being sold for building purposes was loudly condemned. The result is that the Wimbledon residents and the lord of the manor are "in Chancery." The half-finished house in the neighbourhood of "Jack Straw's Castle," Hampstead Heath, affords ocular demonstration of the frustration of Sir Thomas Wilson's claims. An injunction in Chancery has alone preserved the magnificent view across the heath to Harrow. The right of the lord of the manor to build on the heath at all is warmly disputed by Sir Gurney Hoare and the inhabitants of Hampstead, and the legal decision is expected at the end of the long vacation. These are only three out of many instances in which the vagueness of the rights of lords of manors is causing great public inconvenience. The question is too important, says the *Express*, to be left to the chances of local patriotism, and will, it is hoped, be dealt with effectually by the new Parliament. The Right Hon. W. Cowper, Mr. J. S. Mill, Mr. Shaw Lefevre, Mr. Locke, Mr. Thomas Hughes, and Mr. Charles Buxton are amongst the members who are on the committee of the Commons Preservation Society, and are thus pledged to seek a satisfactory settlement of the law. Another notable case requiring settlement is Epping Forest, "with an indigent cottager on the one side, and the rector, the justices of the peace, and the county families banded together on the other."

For years past the green sward of Blackheath has been gradually destroyed, partly by legalised stealth. Local authority, though aided by the recent Commons Enclosure Act, has been powerless in the matter. It is therefore gratifying to know that the Metropolitan Board of Works has taken this "lung" of London under its charge. Portions of the heath will be planted with trees, and others will be set apart for recreation and equestrian exercise.

DRAINAGE AND DRY SOIL *VERSUS* CONSUMPTION.

PHTHISIS, or, as it is popularly styled, "consumption," is to be found amongst the inhabitants of all climates. That the extraordinary prevalence of the malady in some latitudes is largely dependent on certain atmospherical variations is a circumstance long since recognised by medical men, but until lately, says Dr. Henry Day, in a letter to the *Staffordshire Advertiser*, the difficulty has been very great to point out, confidently, the one special condition which seems to invariably foster the complaint; but at length it has been established that dampness of the soil has a most potent influence for evil in developing this curse of our species. The tenth report of the Medical Officer of the Privy Council, recently issued, affords interesting and valuable information on this point. The diminution in the prevalence of consumption effected by means of well-devised drainage schemes is conclusively shown by the statistics given in the report respecting the following fifteen towns, where the fallen death rates for consumption (per centum) after improved land drainage are as follows:—Salisbury, 49; Ely, 47; Rugby, 43; Banbury, 41; Worthing, 36; Leicester, 32; Macclesfield, 31; Newport, 32; Cheltenham, 26; Bristol, 22; Dover, 20; Warwick, 19; Croydon, 17; Cardiff, 17; Merthyr, 11. Mr. Simon, the medical officer of the Privy Council, being determined to investigate as fully as possible the œtiological relation foreshadowed by the facts ascertained in connection with the drainage of the towns named, commissioned Dr. Buchan to carry out still further researches on a plan both extensive and elaborate. Dr. Buchan's report has now been issued, and from his "Summary of Conclusions" we quote the following:—

> The connection between soil and phthisis has been established in this inquiry by the existence of general agreement in phthisis mortality between districts that have common geological and topographical features of a nature to affect the water-holding quality of the soil; of general disagreement between districts that are differently thus circumstanced; and of pretty regular concomitancy in the fluctuation of the two conditions, from much phthisis with much wetness of soil to little phthisis with little wetness of soil. The connection between wet soil and phthisis came out last year, as above described, in another way—by the observation that phthisis had been greatly reduced in towns where the water of the soil had been artificially removed, and that it had not been reduced in other towns where the soil had not been dried. The whole of the foregoing conclusions combine into one—which may now be affirmed generally, and not only of particular districts—that wetness of soil is a cause of phthisis to the population living upon it.

Mr. Simon, in some eminently practical remarks on the matter, observes:—

> Phthisis, so far as it depends on wholesome circumstances of indoor industry, has since my last report been made preventible under law; and phthisis, so far as it depends on wetness of soil, may easily, in great part, be made similarly preventible. . . . An undrained state of soil, in any place where population is aggregated, answers to the legal intention of the word "nuisance," and I apprehend that even in the present state of the law the local sewer authority is bound to provide that such a state shall not continue through want of proper constructions for drainage. . . . But, at least, the law might unequivocally condemn, so far as detrimental to health, all damming of natural drainage, and for river conservancies it would be a function scarcely if at all less important than that of preventing the pollution of rivers, that they should also, as far as possible, prevent or remedy all such artificial and natural obstructions of water-flow as keep tracts of land sodden with stagnant wetness.

The facts thus brought forward by these eminent medical men are irrefutable, and claim the most serious consideration by those whose special province it is to consider such matters. We hope that in all places where defective drainage exists the authorities will bestir themselves, and thus reduce to a minimum the ravages of so dire a malady as consumption. Dr. Day, in the letter we have referred to, intimates that the drainage of Stafford is far from being perfect.

GUARDIANS' IDEAS OF ARCHITECTS' REMUNERATION.

THE Sunderland Board of Guardians recently commissioned Mr. Greener, an architect, to prepare plans for a new hospital. The guardians, in thus acting, would seem to have been oblivious of the regulations of the Poor Law Board as to new works for purposes of poor relief. These instructions should have been furnished to Mr. Greener, but it seems that they were not sent down by the Poor Law Board until after Mr. Greener had prepared his plans. The plans had to be submitted to the Poor Law Board for approval, and, not being in accordance with the requirements of that body, they were rejected. This made the Sunderland guardians open their eyes, and the matter was discussed at a meeting of the board held yesterday week, when a long discussion arose as to the architect's commission. Mr. Greener had charged according to the regular professional scale—viz., 2½ per cent. on the estimated cost of the building on the plans he had prepared. Some of the guardians were under the impression that Mr. Greener ought to make a totally new set of plans, embracing all the requirements of the Poor Law Board, for one commission—*i.e.*, that he should only be paid for the plans ultimately adopted. But Mr. Greener, having been positively commissioned and definitely instructed as to the preparation of the first plans, maintained that, having executed the plans in the manner stipulated, he was entitled to the commission. It was not his fault that the plans were not in accordance with the Poor Law Board's regulations, and he ought not to be made to suffer. At the same time, he was willing to so modify his plans as to meet the views of the Poor Law Board, and would endeavour to get them passed. Now, from this it will be seen that while Mr. Greener made a determined stand against injustice, he was not unreasonable; but his claims were sought to be ignored, and, from a report in the *Sunderland Times*, it seems that something near akin to bullying was resorted to by some of the guardians. But one of this body, who seems to have had a notion of fair play, spoke up for Mr. Greener, and at length the guardians unwillingly admitted the justice of Mr. Greener's claims, although a doleful lament was heard as to the hardship of the ratepayers having to pay £91 5s. (the amount of the work to be done being £3,000) for plans that might not be used. But these guardians were quite conscious that the ratepayers would know on whom to settle the blame.

EARLY CLASSIC ORNAMENT.

DEVELOPMENTS OF NONCONFORMIST CHURCH ARCHITECTURE.—V.

THE third method of gallery arrangement, and the most promising one, is what we have called the "transept system." Its distinctive feature is that of placing the galleries in recesses formed for the purpose, such, for instance, as shallow transepts. This system evidently interferes far less with the structural lines of the building than either of the preceding ones. In the "theatre system" the gallery front and its adjuncts are the most prominent features of the interior; in the "balcony system" they still form an overpowering horizontal mass; in the "transept system" they are no more than a series of short horizontal lines stopped by the vertical ones. On the first arrangement a number of columns are inevitable. On this there need not be one in the whole interior. Height and dignity of proportion are everywhere gained, and there is an end to that bane of chapel architecture—the wide single span roof. With such advantages it is strange that the system has not found more favour; but the unwise use which has been made of it partly explains the fact.

The commonest shape in which it has been tried has been that of a plan nearly in the shape of the letter T. The vertical arm is long and narrow; the cross arms receive the galleries, and the pulpit stands at or about their junction. Now, a place of this kind will evidently be a bad one for speaking in. The preacher's voice is lost in the transepts, and fails to reach the end of the building. The people in the galleries, too, find themselves almost hidden from the rest of the congregation. The galleries, therefore, become unpopular; it is not thought "respectable" to sit there, and so many "sittings" are thrown away. Considerations like this last one have a weight which architects may contend against in vain, and it is, therefore, best to take them into account at first starting. But the plan just described is far from being a fair instance of the system. No. 7, in our last illustration, shows it turned to much better account. This is taken from Messrs. Lanyon and Lynn's design for Trinity College Church, Edinburgh. Here there is a central octagon of 50ft. diameter, with four radiating arms. One of them forms a short chancel, the rest are adapted for galleries. There is nothing to obstruct the view of the pulpit, there is ample space and air, the congregation are grouped around the speaker, and every line of the building proclaims its purpose. Externally it is equally effective, with far more genuine ecclesiastical character than the would-be churches noticed in our first paper. The idea is capable of further development. A grand central space, like that seen here, might become a most impressive and even magnificent feature, rather enhanced in effect than otherwise by the surrounding galleries. As to the external treatment, many ways will present themselves, all free from the shapeless awkwardness of the stereotyped Nonconformist church. Why is it, then, that such a form has not been more studied as a basis for design? Is the fault on the part of chapel-designers or on that of committees? Have that small clique who, to Nonconformists, represent the architectural profession, worked themselves into so deep a rut that they cannot get out of it? While their clients remain contented, they are scarcely likely to try. They have too much reason to perpetuate a state of things which, for them, economises both time and labour and brains. The mystery is that there is so much satisfaction on the other side, that no one longs to strike out a new path, and to introduce a type of building with some nobleness and fitness of character.

The remaining plans, in our last page of illustrations, are inserted as suggestive of particular ways in which advance is possible. No. 8 (the plan of St. George's Church, Tufnell Park), designed by Mr. Truefitt, shows an attempt to group the congregation closely around the speaker. We commend the idea to those Nonconformists who prefer churches which, like this, are destitute of galleries. If they wish, so far, to evade one great difficulty in design, it does not follow that they must introduce the long nave and aisles still absurdly repeated by many of their Episcopalian neighbours. There is still less reason why they should crowd their buildings with such a multitude of pillars as they sometimes do. This folly is becoming a thing of the past even in the Church of England. Such an example as that of St. James the Less (No. 10), designed by Mr. Street, will show that excellent effect can be obtained with no more than two columns on each side of the nave. It is curious, however, that even in imitating Church of England designs, Nonconformists are so far from imitating the best of them. Instead of keeping up with the latest advance in art, which generally coincides with the least amount of unfitness for their own purposes, they appear to have seen nothing of later date than twenty or thirty years ago. It may, perhaps, be useless to tell them that the work they copy is weak and inferior; that the first efforts of the Gothic revival contained many follies and puerilities now abandoned. But there is one argument that cannot fail—they are decking themselves out in a style that is no longer fashionable.

A row of large columns is undoubtedly one of the most inappropriate things which can mar the design of a Nonconformist church, and the majority of chapel promoters are wise enough to object to it; but to reject a feature when it becomes practically inconvenient is one thing; to forbid its use under all conceivable circumstances is quite another. Numbers of persons of the class just referred to show the same aversion for a stone column which a bull does for a red rag, and with an equal amount of intelligence. No matter where it is placed, whether it obstructs the view or not, it is an abomination to them. It is just such irrational prejudices as this which make half an architect's troubles. The natural difficulties to be conquered in designing a good Nonconformist church would give him work enough; but when to these are added all the unreasonable fancies of the people he is working for, the problem set him becomes fairly insoluble. Now to introduce (say) only two or three substantial columns in a design would often give immense advantages. They could be placed where not a single seat would be hidden by them, and where, from the modifications they would admit of in the roofing, they would greatly improve the acoustic properties of the building. Yet to attempt it would in many cases be hopeless, and in a chapel competition ruinous. Supposing, however, the prejudice to be overcome, a great source of variety would at once be gained. Up to this point we have had to do with buildings destitute of any columns, unless it were iron ones, which, by the way, spoil a good many sittings in the aggregate, without the least complaint being made about them. It is one of the commonest things to find a chapel with twenty iron columns, ten below the galleries and ten above. At least twenty, and probably forty or fifty persons are inconvenienced by them, and yet everyone thinks this quite a natural and proper state of things. But should an architect be adventurous enough to insert a couple of stone columns, which at worst could not deprive a dozen people of their view, the outcry is really astonishing. In this, as in other points, a little common sense is the first requisite to improvement. It is quite right to condemn obstructions, but let the principle be carried out fairly and uniformly. Such plans as No. 7 would then plainly have the preference. Next to them would be those with a few columns judiciously placed, and last of all, those which now form the great mass of designs, such as No. 1 in our first plate.

Of the system now suggested, that in which a very limited use is made of stone shafts, few existing instances can be given. The first fact that presents itself in searching for examples bearing on the difficulties of Nonconformist church design is the scarcity of buildings of a monumental class free from internal columns. However else they may differ, temples, mosques, basilicas, and churches all agree in this respect. But there are great variations, arising from the special conditions of each case, in the *amount* of columniation. We have shown a few of the types in which it is smallest, not that any of them are fit for literal repetition, but because even rudimentary ideas are worth having in a case like the present one. No. 11 is a church of the fifth or sixth century, that at Galb Louzeh, from M. de Vogue's very interesting work on the architecture of Central Syria. With its small number of piers, its short chancel, and its large narthex or porch it comes nearer, at any rate, to the form we are in quest of than do most churches of a later date. No. 12 is the plan of St. Sophia, Trebizond, in which four shafts, less in size than the last, produce a very picturesque effect both externally and within. No. 13, from Revoil's "Architecture Romane," is the Abbey Church of Thoronet; and No. 15, from the same work, the Church of St. Martin de Londres, Herault. No. 14 shows the very early but magnificent church of St. George, at Thessalonica, as given in Messrs. Texier and Pullan's work on "Byzantine Architecture"; suggestive, even here, of some thoughts about the path which has been travelled from the almost indestructible grandeur of ancient work down to the transitory shams of to-day. It is comforting, after all, to remember that nineteenth century "chapel Gothic" is not likely to be sketched and measured twelve hundred years after its erection. But without any risk of this kind it would bear to have a considerable addition of solidity. Strength and massiveness of construction are far more telling qualities than mere ornament, and anything which would do away with thin walls, weak carpentry, and lath and plaster, would make a valuable revolution indeed. It is partly with this aim that the less frequent use of iron columns is to be desired, and the introduction of more durable substitutes. How to effect this without interfering with the convenience of the congregation is a problem to be answered differently, it may be, in each separate case. No. 16 is a plan slightly altered from that of St. Martin's, Haverstock-hill, lately built by Mr. E. B. Lamb, in which the four piers used to aid the internal and external design are nearly unobjectionable in position. The rest of our plans may be worth noticing for particular points. No. 17 is adapted for three galleries on the "transept system," which might be carried by girders without any other support. No. 9 is the plan of the Sinclair Seaman's Church, Belfast, by Messrs. Lanyon and Lynn, an L-shaped building, with the pulpit at the angle. No. 18 shows the plan of a Congregational church, built by Mr. Waterhouse, at Manchester, and adapted to a wedge-shaped site. The gallery is indicated by the dotted line.

In concluding this series it is proposed to notice some minor features of Nonconformist churches, as well as that general ideal which it would seem most desirable to aim at in their design.

THE NATIONAL ART LIBRARY AT SOUTH KENSINGTON.

YEAR by year the number of students who use the art library at South Kensington increases, notwithstanding that the "arrangement which can scarcely be called accommodation"—we use the words of the keeper of the library—becomes yearly worse and worse. At present the table space available is barely 2ft. to each reader; in the British Museum 5ft. is allowed to every person. The library, moreover, is badly lighted and very inconvenient. As the keeper says, the completion of a building not merely utilised as a library, but constructed for one, will prove the only effectual re-

medy. The sooner this is accomplished the better. Elbow room is absolutely necessary to art study. The books are often of much larger dimensions than ordinary, and valuable drawings, lithographs, &c., are very liable to damage from the want of a proper amount of space whereon to inspect them. With all its disadvantages the collection of literature it contains is so valuable to students that its use has considerably increased; with increased facilities its value might be trebled.

ARCHÆOLOGY.

A FEW days ago the Rev. Edmund Kell and Mr. Charles Lockhart found the relics of a Roman building in Castleford on Andover Downs Farm, belonging to Mr. Joseph Turner, where one had been discovered by them last year, of which an account was printed in the "Journal of the British Archæological Association" of last September. The relics now discovered, situated 256ft. westward of the former building, are far inferior in quality, and in a very dilapidated condition. Being situated higher up the slopes of the hill, where the mould was comparatively thin, they were constantly exposed to the action of the plough, and of course the farmer would remove the dislocated stones. There was the same description of pottery, Samian ware, nails and other iron articles, bones of edible animals, oyster shells, &c., as in the relics of the first building exhumed. The discovery of these Roman relics is valuable to the antiquary as establishing the position of the Roman station Vindonum, the neighbourhood of which near the intersection of the Roman road from Silchester to Salisbury with that from Winchester to Cirencester had been conjectured, but not proved, by Sir Cecil Colt Hoare in his "History of Wiltshire." The relics of the building discovered last year were oblong, 66ft. 6in. long by 41ft. 2in. broad, with a portico 2.ft. long by 14ft. broad. The walls, 2ft. thick, were composed of flints embedded in mortar. The direction of the building was N.N.W. The roof, which had been composed of hexagonal stone tiles, had been supported by fourteen pillars at regular intervals, opposite to each other, the foundations of which remained. There were the remains of six fireplaces and three furnaces, but no hypocausts or baths. The building was pitched with stone, and is conjectured to have been a diversorium or inn, and not what is usually called a Roman villa. On the site were found abundance of crockery, Samian ware, coins, nails, and iron articles of various kinds; ox, sheep, hare, horse, and other bones; and oyster and mussel shells.

Referring to the recent meetings of archæologists at Cirencester and elsewhere, the *Herts Guardian* says that it is most desirable to extend the taste for archæological inquiry generally, and this can best be achieved by means of county societies. There is ample field for the exertions of a local society throughout Herts. The only society at present existing in Herts has St. Albans for its head quarters, but this society limits its researches to West Herts, and regards neither the east nor northern portions of the county. And yet there is much to inquire into in these parts of Herts; for though the county altogether is lamentably poor in ecclesiastical antiquities, yet there are remains of old castles, sites of old Roman roads, and other objects which would well repay research and examination. If the archæologists of those portions of the county which are not embraced by the St. Albans Society would communicate with the Rev. R. Gee and the Rev. W. O. Davy, the usefulness of the society might be extended to the whole of Hertfordshire.

The general meeting of the Leicestershire Architectural and Archæological Society was held on Wednesday and Thursday week at Kegworth. On Wednesday, after service, Mr M. H. Bloxam, F.S.A., pointed out the architectural features of the church. The party then proceeded to the schoolroom, where a temporary collection had been made of antiquities belonging to the neighbourhood. Walking parties were then formed for visiting Kingston Church, Ratcliffe-on-the-Soar, and "Tom Moore's stile" on Broad Hill. Returning to Kegworth dinner was partaken of at a local inn, and in the evening a meeting was held in the Mechanics' Institute under the presidency of the Rev. J. Clarke, the rector of Kegworth. Papers were read on "Memorials of Kegworth," by the president; on "Some Discoveries made in the Progress of the Restoration of Lutterworth Church," by Mr. Bloxam; and on "Richard Fowke's Journey to Freestone shore, illustrative of Social Life amongst the Middle Classes at the Commencement of this Century," by the Rev. E. Towers. The usual votes of thanks terminated the meeting. On Thursday the society visited Gotham, Bunny, Wysall, Willoughby, Wymeswold, Rempstone, Cortlingstock, East Leak, and West Leak.

On Tuesday week the North Oxfordshire Archæological Society had a field day at Witney and the neighbourhood. Their first visit was to Eynsham, to inspect the church; from thence to the little church at Cogges. They then proceeded to Witney Church, lately restored by Mr. Street. On Tuesday they visited Minster Lovell, where the church is undergoing renovation; it has a central tower on remarkably solid columns, each with a stone seat round its base, and a tall narrow arch by its side. There are remains of a screen and a rood-loft gallery, and in the vestry north of the chancel the unique feature of a double lagioscope, so that the holy services of the altar may be seen by a person either inside or outside the vestry room. The monument to Henry Heylyn was absent for repairs. The remains of the ancient mansion of the Lovells excited admiration from their elegance of design, loftiness of build, and solidity of masonry. The proceedings concluded with a visit to the museum at Witney, over which the visitors were conducted by Mr. Thomas Purdue.

WATER SUPPLY AND SANITARY MATTERS.

THE disposal of the sewage is now exciting a large share of attention in Merthyr Tydvil. A system of main drainage has lately been completed, and the sewage matter, after being deodorised, has been discharged into the River Taff, about four miles below the town. The Local Board of Health have, within the last fortnight, been threatened with an injunction to discontinue this practice, in consequence of the nuisance which it is alleged it occasions. This has placed them in a position surrounded by many difficulties, the chief of which is what to do with the sewage matter if an injunction be obtained. The nature of the district—a narrow valley, on each side of which rise steep hills—precludes irrigation, and the only other means of utilising sewage appears to be by converting it into manure, on the same principle as at the Stroud works. This the town surveyor recommends, and it is a plan that is likely to be adopted, as many of the members of the Board are themselves in favour of it.

Building Intelligence.

CHURCHES AND CHAPELS.

The foundation stone of a new aisle to St. Pancras Church, Chichester, was laid on Monday week.

On Wednesday week the foundation stone of a new Wesleyan Chapel was laid at St. Lawrence, Kent. Sittings will be provided for 200 persons.

St. Michael's Church, Stinsford, Dorsetshire, has been restored, under the direction of Mr. Hicks, architect, of Dorchester; Messrs. Wellspring and Son being the builders.

On Thursday week the Bishop of Ripon consecrated the new church of St. Anthony, Newcastle-on-Tyne. The edifice consists of a chancel 30ft. by 22ft., and nave 63ft. by 24ft. 6in., south aisle 10ft. wide, and an organ chamber and vestry. The style is Early Pointed, and the materials are red brick, with bands of dark-coloured bricks introduced in the interior. Messrs Austin and Johnson, of Newcastle, were the architects.

On Saturday the memorial stone of a new Methodist Chapel was laid at Ilkley, Yorkshire. The style of the building is twelfth century Gothic, and it will seat 650 persons, at a cost of £3 500. Messrs. Andrews, Son, and Pepper, of Bradford, were the architects.

A new Wesleyan Chapel at Ceprinion, in the Knighton circuit, was opened on the 19th ult. It is in the Norman style, and was built from the designs of Mr. Pugh, of Bishop Castle.

On Wednesday week a new Unitarian Chapel was opened at Hunslet, Yorkshire. The building is of Potternewton delphstone, with Meanwood sandstone dressings, designed in Early English Gothic, and is 52ft. long by 30ft. wide. The total cost, including the land, is about £1,700. Mr. Alexander Crawford, of Leeds, is the architect.

The annual general meeting of the Carlisle Diocesan Church and Parsonage Building Society was held on Thursday week at Penrith. From the report it appeared that £713 had been granted towards the erection of churches and parsonages.

The foundation stone of a new Primitive Methodist Chapel was laid at Theale, near Reading, on Monday week. Mr. May, of Ufton, is the contractor.

The new church of St. Patrick, at Jordanstown, has been consecrated by the Lord Bishop of Down and Connor and Dromore. The general style of the building is Mediæval—that of the tenth century. The material used is white sandstone, relieved with red brick for the exterior; while red and black brick, with sandstone dressings, were used for the interior. The chancel is 24ft. long by 18ft. wide, with semicircular end. The pulpit is of stone. The cost was about £3,000.

A new Presbyterian Church has been opened in the town of Killarney. The style is Gothic. Sittings are provided for about 120 persons. The total cost was about £1,000. Mr. Francis Norman was the contractor.

The church of St. John the Baptist, Hey, is at present undergoing repair and enlargement, at a cost of £2,000.

Emmanuel Church, Brighton, was recently opened. The edifice has a frontage of 104ft. in Norfolk-terrace, and of 72ft. in Belvedere-terrace. The walls of the interior are polychromatically decorated. The stained glass windows have been supplied by Mr. Bell, of Camden Town. The sittings (1,500 in number) are of stained deal. The roof is of iron, and covered with iron externally, and the stairs leading to galleries are also of iron. The cost has been £5,000. Messrs. S. C. Hemming and Co., of London, were the contractors.

BUILDINGS.

A new railway station was recently opened at Taunton. The length of platform under roof is 250ft.; width of roof, 88ft.; height of apex of roof, 42ft. Messrs. W. Brock and Co., of Bristol, were the contractors.

The foundation stone of a new industrial school was laid at Mossbank, near Glasgow, on Wednesday week. It will be built of red, black, and white bricks, and will be 240ft. in length, and three stories in height. It will contain 1,000 children, at a cost of £900.

The bullion court of the Bank of England is being cleaned and repaired.

Shepherd's Hotel, at Cairo, has been destroyed by fire. This may lead to a building operation. The adjoining hotel of the Oriental Hotels Company, by Mr. Tompson, cost £120,000. Shepherd's had been a palace of Mehemet Ali Pacha, and now belongs to H. H. Kiamil Pacha. It is on the site of General Bonaparte's head-quarters and of Kleber's assassination.

St. Hubert's Hall, Great Harwood, Lancashire, was opened on Monday week. It has been built for the use of the Roman Catholics in the town, as a place in which to hold social meetings, &c., at a cost of £950.

The foundation stone of six almshouses was laid at Stilton the other day. Mr. Hutchinson is the architect, and Messrs. Tyres, Ireson, and Richardson are the contractors. The cost will be £450.

The old hospital building in Little Park-street, Coventry, has recently been purchased, and has undergone extensive alterations and improvements adapting it for a county reformatory for girls. Mr. Steane, of Coventry, was the architect.

By the liberality of a resident a new village hall is to be built at Cheriton, in Kent, to accommodate 100 persons. The style will be Gothic, and it will be built of Bath and Kentish rag stone, faced internally with coloured bricks, at a cost of about £1,200. Mr. J. Gardener, of Folkestone, is the architect.

A new bank has just been erected for the Midland Bank at Oundle, Northamptonshire, from the design of Mr. Browning, architect, of Stamford. The carving of the capitals, of polished serpentine, which ornament the front, is by Mr. William Hilliam, of Stamford.

Messrs. George Angus and Co.'s new warehouse and office, &c, in Grainger-street West, Newcastle-on-Tyne, was opened a few days ago. The general plan of the building is somewhat of the L form, measuring about 140ft. in the longer and 90ft. in the shorter arm, by an average width of 45ft. The front building consists of large shops, with a spacious cart entrance in the centre, leading to the cellars, large warehouses, and workshops behind. Over the shops are two stories of offices and attics. The style of architecture is Italian Gothic, successfully adapted to commercial purposes. The building was formally opened on the 26th ult. by the Mayor of Newcastle, Henry Angus, Esq., at a luncheon, held in the warehouse. The architect is Mr. Gibson Kyle, of Newcastle. The contractors are Mr. R. Robson, mason; Messrs. J. and W. Lowry, joiners, &c.; Mr. R. Richardson, painter, &c.; Mr. H. Watson, plumber; Mr. Curry, carver; Mr. Beck, slater; Mr. J. Charlton, plasterer.

The buildings and site of the old city gaol at Worcester have been purchased by a gentleman, and a portion of the edifice has been converted into almshouses. The foundation stone of a new church on part of the site was laid last week.

The china and earthenware manufacturers of the Staffordshire Potteries, as represented by the local Chamber of Commerce, have concluded a convention with their workmen for the settlement of trade disputes by arbitration. The board to whom future differences are to be referred is composed of ten manufacturers, nominated by the chamber, and ten workmen appointed at a large public meeting held last week at Hanley. It is a noteworthy fact that one of the first questions addressed to the Liberal candidates for the representation of the Potteries was, "Will you vote for a legislative enactment making the decision of boards of arbitration binding on the parties appealing to them?" The affirmative answers given were loudly applauded.

TO CORRESPONDENTS.

NOTICE.—Cases for binding the BUILDING NEWS, Vol. XIV., are now ready, price 2s. each.

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

RECEIVED.—S. W.—W. M. jun.—I. M. S.—I. C.—I. B. R.—T. G.—I. A. D.—T. O.—C. B. A.—I. P. S.—W. H. B.—W. B.—B and Son.—S. S.—J. Redford.—W. E.—J. M. S.—S. K. M.—A. S. P.

BUILDING SOCIETIES.

To the Editor of the BUILDING NEWS.

SIR,—Your correspondent, Mr. E. Ingress Bell, has drawn attention to a most important question in relation to building societies, but has he not fallen into a misapprehension as to their scope and object, and been thus led to undervalue their utility?

A building society is really a deposit bank and loan fund—nothing more. It receives the deposits of its members, allowing interest upon them, and lending the money to such of the members as may wish to borrow. The interest paid to the depositors is paid out of the profits made by the higher rate of interest paid by the borrowers. It is obvious that the depositors could not receive 5 per cent. if the borrowers only paid that rate. The error is not in charging a higher rate of interest to the borrower than they pay to the depositor, but in professing to charge only 5 per cent. when the rate is really 7, 7½, or 8 per cent. Some of the best societies, as, for example, the National Freehold Land Society, which works in alliance with the British Land Company, adopt a clear and unexceptionable principle of action in this respect. That society advances money to purchasers of lots upon the estates of the British Land Company at 5 per cent., but it is 5 per cent. upon the balances remaining unpaid; and to all borrowers for building purposes they charge 7 per cent., but that is upon the balances due, so that a man who has paid off £700 out of a loan of £1,000 is paying 7 per cent. upon £300 only, while, in the case censured by your correspondent, 5 per cent. is paid upon the £1,000 until the whole is paid up. I agree with him that it is an unbusinesslike proceeding, and one that calls for correction. I do not agree with him, however, that the rate of interest is too high, nor do I subscribe to the opinion that it is better for a man to continue to pay rent. The great advantage is overlooked by him of a man becoming by these payments the owner of his own house. He may, it is true, rent a house for fifteen years on easier terms than by buying one through a building society, but this is not always the case; but at the end of the fifteen years he is just where he began, while, after his money is paid to the building society, the house is his own. I am sure that if he looks at the whole case he will not in future discourage building societies, but endeavour to make them more efficient by correcting the errors in practice, one of which he has pointed out.—I am, &c.,

Masbro', August 31. S. S.

SIR,—I think the letter in your journal of last week from Mr. Ingress Bell will induce many persons to entertain doubts as to the benefits derivable from the operations of land and building societies; will you therefore permit me to offer a few observations in reply?

I may at once state that I am not officially connected with any society, but have watched the progress and working of several for many years past.

Your correspondent expresses an opinion that an exorbitant rate of interest is exacted by these societies, and that it would be much better to continue the payment of rent for a few years and invest an amount for the purchase of a house without the aid of a society. Let us see what the result would be, and for illustration one case will be as good as a hundred.

Say for the villa in which I reside the landlord receives £36 a year rent, and I could obtain the lease of the property for £300. I borrow that sum from a building society and purchase the house, repaying the amount by 120 monthly instalments of £3 10s., including principal and interest, or £42 per annum, to which add £8 for ground rent, insurance, &c., making the yearly charge £50, or a total outlay in ten years of £500. The present rent being £36 I shall have to provide an additional sum of £14 a year to meet these payments for ten years, and at the end of that period shall have paid to the society £420, being the £300 borrowed, plus £120 as interest, or about 8 per cent. per annum.

The building societies of course are not all conducted upon exactly the same principles, but the chief of them do not differ materially in their general results.

Now if instead of obtaining the house through the assistance of a society I invest the £14 a year at 4 per cent. interest (and where can it be safely placed at a higher rate?) until it accumulates to £300 with the view of buying a house of that value, I must wait fifteen years and pay rent in the meantime amounting to £540 (£36 × 15), which being added to the total sum invested, viz., £210 (£14 × 15), makes the outlay £750, or, £250 more than would be incurred by purchasing the house with the aid of a building society.—I am, &c., S. S.

London, September 2.

ANOMALIES UNDER THE METROPOLITAN BUILDING ACT.

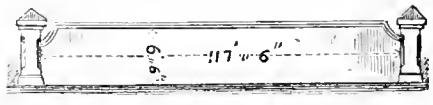
SIR,—The Metropolitan Building Act, though, on the whole, its existence and enforcement have had a wholesome effect, would appear to be by no means an unmixed good. The endless disputes that have arisen, and the conflicting decisions arrived at by magistrates before whom the summonses have been heard, convey anything but a salutary impression of the dignity of the law. When the law ceases to be certain in its operation it loses its dignity. The greater the number of interpretations that can be placed upon a statute the greater is the blame attaching to those who placed it on the Statute Book, and, accepting this dictum as sound, the framers of the Metropolitan Building Act have, by all accounts, much to answer for. At least, we may reasonably come to such a conclusion when we find so much disputation as to the meaning of this or that clause. But the obscurity of meaning of some of the clauses is not what I wish to draw attention to now. From reading the report of a case recently heard before Mr. D'Eyncourt at the Marylebone Police Court, I have been struck with the thought that there must be something radically defective about the act. Under its provisions, as is now pretty generally known, every district of London is under the surveillance of a surveyor, whose duty it is to see that the requirements of the act are complied with in all erections within their respective districts. Now, from the case I have referred to, it would appear either that the provisions of the act are so ambiguous as not to be alike comprehensible by those appointed to carry them out, or that those so appointed, from motives best known to themselves, or from no motives at all, are capricious in their rendering of the act. In the case mentioned Mr. Samuel Simpson, builder, of Tottenham Court-road, was summoned by Mr. Alexander Peebles, district surveyor for the northern division of St. Marylebone, on account of not having complied with the provisions of the act in executing certain portions of the works required in the alterations now being carried out at the Marylebone Theatre in fireproof materials. The builder's defence was that he had built the new Queen's and the Holborn Theatres, and that they were built on precisely the same principles as the works now condemned by Mr. Peebles; and that, moreover, the plans for both those structures met with the approval of the district surveyors in those localities. Mr. Simpson said that he was also the contractor for the new Gaiety Theatre, in the Strand, and the plans for that edifice, though similar to those of the Marylebone Theatre (so far as the point at issue was concerned) had met with the approval of the surveyor in that district. Furthermore, the plans now condemned by the Marylebone district surveyor had been "passed" as satisfactory by an official at Spring Gardens, acting on behalf of the superintending architect of the Metropolitan Board. Taking the accuracy of the builder's statements for granted (and none of them were impugned) it really does seem a gross anomaly that, with all these precedents on his side, judgment should be given against him. I do not call in question the justice of the condemnation. Mr. D'Eyncourt is one of the most experienced of metropolitan magistrates. There is every probability that his decision is right. But, whether right or wrong, the uncontradicted statements made by the builder give no flattering picture of the working of the act. Are the duties of district surveyors so loosely defined that some act in direct opposition to others? And when plans are "passed" at head-quarters, does it savour of sound management when subordinate officials reject such plans? And if, in the future the Queen's, the Holborn, or the Gaiety Theatres are destroyed through not being erected on the fireproof, or supposed fireproof, principles enjoined by the act, will the Metropolitan Board or its officers, the district surveyors, be liable to an action for damages? We certainly cannot but marvel when we read of public officers being so widely divergent in opinion as to the path of public duty. If it arises from ambiguity of expression in the act, why does not (if the act cannot be intelligibly amended) the Board issue an authoritative manual or handbook explanatory of the act? Certainly those who administer the law should understand the law. I don't know how the district surveyors are off for work, but I think they ought to keep a sharper eye on the bad materials and workmanship that seem to be so common now in some of the suburbs. At least, that is the opinion of one who is

NOT A PROFESSIONAL.

THE ART OF BUILDING IN CONCRETE.

SIR,—Having read with much interest your articles I., II., and III. on the different modes of concrete building in your last numbers, I trust you will not think it out of place my sending you the result of my experience. After having completed the concrete work for the house at East Sheen satisfactorily with Mr. Tall's patent apparatus, containing thirty rooms with passages, all with fireproof floors in the same material, I now give the result of my experience at this place, under Mr. W. F. Hooper, surveyor, with the same apparatus.

I started on Wednesday morning, the 19th inst., at nine o'clock, on a house 41ft. by 38ft. 6in., and by the 21st inst., it was 6ft. 4in. high all round the building, all the external walls being 12in. thick, and two internal walls, containing the flues, 15in. thick, the number of hands employed being four only. I have also on the same grounds erected two boundary walls 117ft. 6in. long, each 6ft. 6in. high, and 6in. in thickness, with a pier at each end only, thus—



These walls are admired by all who call to see them, and I would ask any practical man with a knowledge of concrete if he can name another system, with blocks or otherwise, that can produce the same result?

With reference to the cost of the apparatus, I am given to understand that the patentee is willing to take it back after the completion of these works, and allow one-half the value paid for it, which arrangement, combined with the inexpensive system of building as compared with the ordinary mode of building, will show a considerable saving; and it further strengthens my opinion that, with these arrangements, anyone desirous of building two or even one cottage, would find it exceed their most sanguine expectations as regards the great saving between building in concrete and ordinary brickwork, with the addition of all the advantages connected with concrete building, such as a more substantial house and a much warmer house in winter, the walls being quite impervious to damp and vermin, and the system providing a sure cure for a smoky chimney, with minor advantages. I shall be glad to show the works here to any gentleman interested in this system of building.—I am, &c.,

H. R., Clerk of the Works.

Ailsa Park, Twickenham, August 26.

ST. ANDREW'S CHURCH, MONTPELIER.

SIR,—I notice in your paper for last week a short account of the "improvements" in the church of St. Andrew's, Montpelier; but, in the cause of art, religion, and good manners, will you allow me to ask if costly gifts are to be set aside at any time incumbents may see fit? If so, there is

not much encouragement given. Would it not have been much better if the centre panel of the said reredos had so been coloured as to throw out in bold relief the symbol of our redemption that has for some time past stood upon the super altar of this church, instead of casting it aside, to the insult of its donor—yes, and of Him whose sign it is, as well as to the deepest regret of many devout communicants at that altar?—I am, &c.,

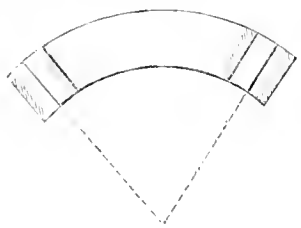
AN ARCHITECT.

Intercommunication.

QUESTIONS.

[998.]—GOTHIC ARCHES.—Will any of your readers kindly inform me what book (if there is any) will give me examples of the four periods of Gothic architecture, viz., Lancet, Geometrical, Curvilinear, and Rectilinear, and where it may be got; also the price?—W. E., Salford.

[999.]—GOTHIC ARCHES CIRCULAR ON PLAN.—Allow me to thank "S. Lewis" for his attention to my query—"Gothic Arches Circular on Plan;" but his answer does not suit my purpose. The method he proposes is for an arch cutting square into a circular wall. I want to construct mine with the sides of soffit radiating



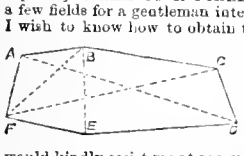
nearly to the centre, as per sketch. It will be observed that the sides of soffit are drawn parallel to the radiating line, and on that plan I am bound to work. I shall feel obliged to "S. Lewis" for working lines for the above; also his opinion as to whether it would be better to have the beds twisted or fair?—CLERK OF WORKS.

[1000.]—CLIPSHAM STONE.—Will you kindly, through your paper, inform me if Clipsham stone is a stone that would be likely to stand the London smoke, as I should like to see some of it used in town, as there is so much decay in some of the stone used in good buildings; and, knowing that Clipsham stone is one of the best weather free-tones in England for all external purposes, I should like the opinions of some of our practical men on the subject.—A SUBSCRIBER AND BUILDER.

[1001.]—PLAN DRAWING AND ARCHITECTURE.—Could any of your numerous correspondents be so kind as to give me the following information?—What is the best course of study necessary to obtain a thorough knowledge of plan drawing and architecture in general, and the works necessary for the same; and is there such a work that treats on Gothic architecture, both theoretically and practically; also for all kinds of church architecture, domestic architecture, &c.; and a good work giving a complete system of lines for stone cutting?—STONEMASON.

[1002.]—HORSE POWER FOR A GENERAL JOINER.—Will any of your readers kindly inform me if they know of a general joiner that is worked with one or more horses; and if so, where it can be seen, and who made it?—I. J.

[1003.]—AREA OF A FIELD.—Having lately surveyed a few fields for a gentleman intending to build upon them, I wish to know how to obtain the total area. I saw in your valuable columns of "Intercommunication" for August 21, a reply about a triangle, and I should be exceedingly obliged to any of the gentlemen who answered the question if they would kindly assist me at present. The line A D is 1,170ft. long; F C, 1,370ft.; B C, 730ft.; B E, 320ft.; B F, 210ft.; F E, 165ft.; E D, 540ft.; C D, 85ft., and A F and A B each equal to 90ft. How am I to proceed to calculate the area of the whole figure A B C D E F?—YOUNG SURVEYOR.



[1004.]—TELESCOPE GLASSES.—Can any of your readers inform me of the reason why the telescopes belonging to engineers' levels and theodolites always view the objects upside down? Is there any real necessity for such an arrangement, or is it merely to bewilder the uninitiated?—QUERY.

[1005.]—FREEZING MIXTURES.—I should be much obliged to any one of your valuable contributors who could explain to me the theory of freezing mixtures, so very much used during the late hot summer, and what chemical ingredients would be the cheapest to employ for the purpose.—S. P.

[1006.]—MOIST WATER COLOURS.—Could any reader inform me how and where I could obtain either porcelain or gutta percha pans for moist water colours, also lead tubes for oil colours?—H. K.

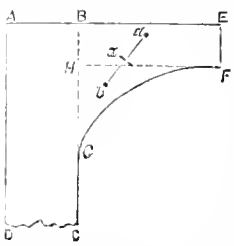
[1007.]—CEMENT FOR GAS AND WATER PIPES.—I want a formula for a cement for gas and water pipes, really impermeable to gas and steam. Perhaps some reader will oblige.—MACHINIST.

[1008.]—RETAINING WALLS.—I am obliged to "Q. E. F." for the trouble he has taken, but if he examines my question (No. 961) he will see that it was not the case of a retaining wall with the earth or water level with the top, but for one with a surcharged embankment. I suppose there is some general rule sufficiently accurate for all practical purposes. Rankine gives one, but long and complex, as he takes into account the pressure of the earth on the top of the wall. To obviate this, in my figure I showed the foot of the slope of the embankment resting against the edge of the back of the wall. With regard to the form of the wall, the back is often built parallel to the face, and very seldom vertical. I have built several on railways abroad, but I think sometimes there has been a useless excess of strength given to them; and in cases where a wall is 30ft. or 40ft. high, with 80ft. of bank above it, it is difficult to judge what is the best form of wall to be used, and of what dimensions it should be built; and some clear, simple rule such as I ask for would, I think, be serviceable to many.—X + Y.

REPLIES.

[962.]—ST. PETERSBURG STANDARD DEALS.—I find in "Intercommunication," No. 962, in my answer to "Builder's" question in No. 710, St. Petersburg Standard, there is a slight error, probably mine. It reads: "A St. Petersburg standard C is 120 planks 12ft. 11in. by 11in., or 60 planks 12ft. 3in. by 11in., equal to 880ft. run of 3ft. by 9in.," which should be "880ft. run of 3in. by 9in., or 73 deals 12ft. 3in. by 9in., and one piece 4ft. over."—W. L—D.

[979.]—CENTRE OF GRAVITY OF ARCH.—The second question proposed by your algebraical correspondent X + Y is a little more complicated than his first, but still admits of an easy solution. In the first place, the part A B C D may be regarded as the pier, and as having nothing to do with the semi-arch. We then have the irregularly shaped piece B E F G, of which it is required to find the centre of gravity. Draw the horizontal line F H, and find the centre of gravity of the semi arch H F G by the method previously given by "Q. E. F." in a former number. Let it be at the point *b*. Next find the centre of gravity of the rectangularly shaped figure B E F H, which will obviously beat its centre at *a*. Having determined these points, draw the line *a b*, joining them, and cut it at the point *x* in the inverse ratio of the weights of the pieces B E F H and H F G, so that *a x* : *x* : : *b* : : weight of H F G : weight of B E F H. The centre of gravity of the whole figure B E F G will be situated at the point *x*.—Q. E. F.



[982.]—STRENGTH OF BRICKS.—Having seen "Hydraulic's" question in your "Intercommunication" columns, I wanted to see the replies. Finding there was no answer inserted in your last issue, I beg to hand you the calculations, thinking it is an important question, which should interest every young architect and engineer:—3in. × 1in. × 1in. : 800lb. : : $1\frac{1}{2} \times 1\frac{1}{2} \times 1\frac{1}{2}$, which = $\frac{1 \times 800 \times 3 \times 3 \times 3}{3 \times 1 \times 2 \times 2 \times 2}$ = 900lb. crushing weight for 1in. cube. As there are 36 of these cubes in the size of the brick given, it would require 36 times 900lb. to crush the brick: 900lb. × 36 = 32,400lb., the crushing weight for a brick 9in. × 4½in. × 3in. —ENGINEER.

[982.]—"Hydraulics" does not state his question very clearly. By $1\frac{1}{2}$ cube does he mean a cube containing $1\frac{1}{2}$ square inches, or a cube of which the side is 1½in. in length. Upon the latter supposition, the number of square inches in the surface of the cube would be $1\frac{1}{2} \times 1\frac{1}{2} = 1.5 \times 1.5 = 2.25$, and the calculation is $2.25 \times 800 = 1800$lb. The crushing weight of a brick will manifestly depend upon the manner in which it is laid. If laid in the ordinary way, as in walls, the strength in pounds would be equal to $9 \times 2 \times 800 = 21600$lb. But if it be laid flat, as in paving, the calculation would be $9 \times 4\frac{1}{2} \times 800 = 32,400$lb.—H. B.

[983.]—PARTY WALLS.—Allow me to inform "H. R. T." that anything overhanging a wall has nothing whatever to do with the boundaries of land. The boundary line will depend upon the plan, and not the elevation of a wall. I cannot understand what "H. R. T." means by a cellar 4ft. square, and therefore am unable to answer the remainder of his question.—CLERK

[987.]—TRUSS.—The strains upon each member of the truss can be solved by the following simple formulæ:—W = the gross weight on the truss; c = the half span; k = its rise; H = the tension along the tie beam; T = the thrust along each of the rafters.

$$H = \frac{W \times c}{4 \times k} \qquad T = \sqrt{H^2 + \frac{W^2}{16}}$$

Substituting the dimensions given in the example—

$$H = \frac{2 \times 7.5}{4 \times 5} = .75 \text{ tons.}$$

$$T = \sqrt{.75} \times .75 + \frac{2 \times 2}{16} = .8125 \text{ tons.}$$

The scantlings should be for the rafters 3in. by 4in.; tie beam, 8in. by 3in.; and kingpost, 3in by 4in. The strain on the kingpost is a tensile one, and in this instance equals one ton.—GEO. E. WALTERS, 25, Englefield-road, De Beauvoir Town, N.

[985.]—PUDDLING ARCHES.—The reason puddle cracks not only when laid over arches, but in any other situation, is that it has not been properly made. A great deal of care and patience is necessary in making puddle, and unless it be thoroughly well beaten up and amalgamated, it will always crack and let in water. The chief thing to attend to in the making of puddle is to mix it well and lay it on in thin layers, one after the other. The only remedy that "T. P." has is to remove a portion of the puddle in the neighbourhood of the cracks and put in fresh, taking care to make the joints good by well punning the material.—M. S. M.

BUILDING AND LAND SOCIETIES.

THE annual general meeting of the Staffordshire Land Building, and Improvement Company was held at Stafford on Monday week. The report and accounts were approved and passed. The retiring directors were re-elected, as were also the retiring auditors, and the usual votes of thanks were passed.

The first annual report of the Monarch Permanent Land, Building, and Investment Society states the total income of the undertaking for the year at £84 946; the sum advanced on mortgage at £83,736; and the balance of profit at £4,750. Interest at the rate of 5 per cent. has been paid upon the fully paid-up shares.

WAGES MOVEMENT.

THE manufacturers and operatives of the Staffordshire Potteries have just formed a Court of Conciliation and Arbitration for the settlement of disputes in the pottery trade, consisting of ten employers and ten workmen. The operative members of the court were appointed on Wednesday week evening at a large and enthusiastic meeting of potters at the Townhall, Hanley, at which Mr. J. Ayshford Wise, formerly M.P. for Stafford, presided.

The strike of the bricklayers in New York continues unabated. The attempt at compromise on the part of the masters and men has failed, and both sides seem determined to remain firm. In view of this, the bricklayers have resolved to form a co operative railway company, with a capital of 20,000 dollars.

STAINED GLASS.

A MEMORIAL window for the chancel of Peel Chapel, Hulton, has just been completed by Messrs. R. B. Edmundson and Son, of Manchester. The window is in three divisions, and is composed of four large panes of plate glass; upon these are depicted the "Ascension of our Saviour" and figures of St. Peter and St. John, to whom the chapel is dedicated; the subordinate parts are embellished with appropriate symbols and inscriptions, and enclosed within borders of Classic design; the cartoons were prepared by Mr. S. Le Resche.

Three stained glass windows have just been placed in Tur Langton Church, Leicestershire, from the works of Messrs. Heaton, Butler, and Bayne.

A new stained glass window has just been placed in St. Peter's Church, Droitwich, by Messrs. A. and W. H. O Connor, of Berners street, London.

One of the windows in the north aisle of Westminster Abbey has just been filled with stained glass, manufactured by Messrs. Heaton, Bayne and Butler, from the designs of Mr. Henry Holiday. It is placed there as a memorial to the late Isambard Kingdom Brunel, who died in 1859. The architectural framework consists of two tall and graceful lancet arches, surmounted by a quatrefoil opening in the head of the principal arch. The artist has filled the quatrefoil head with a Christ in glory, surrounded by hovering angels with censers. Each of the lower lights contains three subjects from the history of the Jewish Temple, and the lowest portion of each is occupied by two allegorical figures, those on the western side representing Fortitude and Justice, those towards the east Faith and Charity. Among the incidents from the history of the Jewish Temple are the Presentation, Solomon Praying at the Dedication, and the Child Christ among the Doctors.

STATUES, MEMORIALS, ETC.

THE Albert Memorial, standing exactly opposite to the Central Hall of Arts and Sciences, has now reached its greatest height. The cross which forms the apex is in its place. The broad flights of granite steps cover a large space, and have a good effect. From the centre of these rise the pedestal and canopy to support and cover the statue of the late Prince Consort.

A tablet, Celtic cross, or cairn, is to be erected to the memory of Alexander III., on the King's Rock, between Burntisland and Kinghorn, being the spot to which the body and horse of the king are believed to have rolled after falling over the cliffs above.

The Birmingham Town Council has just granted a site for the erection of a statue to James Watt. The site is at the junction of Ratcliff-place with Paradise-street.

LEGAL INTELLIGENCE.

ON Tuesday last a new provision in the new Inland Revenue Act took effect, by which, in the stamp duty, the mortgage duties on leaseholds may be omitted in the amount chargeable.

INJUNCTION AGAINST THE BRADFORD CORPORATION.—A bill has been filed in Chancery by Mr. W. R. C. Stansfield, of Esholt Hall, against the Corporation of Bradford, to restrain them from causing or permitting to pass into the River Aire any sewage, filth, or other offensive matter either solid or liquid, from the Bradford beck, in such a manner that the same may pass therefrom into the said River Aire to the injury of the plaintiff, and from in any manner polluting the said river in its course past the Esholt Hall estate. And from allowing any sewage, filth, or other offensive matter to pass from the Bradford beck into the said River Aire. And upon special affidavits filed before the Master of the Rolls, and without notice to the Corporation, his Lordship has made an order, on *ex parte* statements, restraining the Corporation until further order from opening or permitting to be opened any additional main or branch sewer, or any house drain, or sewer, into the outfall sewer, or into Bradford beck, or any sewer communicating therewith, or emptying itself therein. And notice has also been given of an intended application for an extended injunction to the whole of the sewage on the first seal day next Michaelmas term. The bill was filed on the 28th ult., the application for the interim injunction was made on Monday, and a copy of the bill and notice of injunction were served yesterday on the Town Clerk of Bradford.

Our Office Table.

The cost of watering the streets of London during the past season is stated at £100,000.

Mr. W. F. Laurence, contractor for the Lynn Dock Works, has undertaken the contract for the Bristol Port and Channel Docks. The amount of the contract is £600,000.

The Local Board of Health of Farnham has just awarded to Mr. Richard Hasard and Mr. John Anstie, of Devizes, the first premium of 100 guineas for their plans for the drainage and the utilisation of the sewage of the town. There were twelve or thirteen other competitors.

Paris is about to have the accommodation of an underground railway—more, however, for bringing in market produce from the suburbs than for passenger traffic. It will start from the Halles Centrales at the end of the Rue St. Honore, and take the line of quays as far as St. Cloud, whence it will proceed to La Marche, where a large station will be built, forming the starting point of a new circular railway, passing entirely round Paris at several miles distance. The works are to be commenced in the Champs Elysee, between the Palais de l'Industrie and the Place de la Concorde.

The portraits of the Sovereigns of France, and of the architects and artists who had co-operated in erecting and adorning the Louvre, in number twenty-five or thirty, and executed in Gobelins tapestry, have been removed from their frames and sent back to the manufactory to be, if possible, repaired, as they have been greatly moth-eaten. They cost originally 200,000 francs, and have been fixed on panels in the Apollo Gallery for the last two or three years.

St. Joseph, the reputed father of our Saviour, is generally described as a carpenter. During the late visit of the British Archæological Association to the picture gallery at Charlton House Mr. Black pointed out that the original term used signified architect, builder, or mason. He stated that the designation carpenter was a complete misnomer, no wooden buildings having been erected in the Holy Land, where St. Joseph lived, stone only being used in the construction of the houses.

At the recent meeting of the British Association at Norwich, Professor Leone Levi read a paper in Section F (Economic Sciences and Statistics), "On the Progress of Learned Societies illustrative of the Advancement of Science in the United Kingdom during the last thirty years." The Professor had divided the different arts and sciences into eight distinct groups. Group *d*, comprising geological, antiquarian, archæological, historic, and architectural science, shows an advance in membership of 373 per cent. during the past thirty years; and group *e*, "Applied Science—Society of Arts, Engineers, Architects, Pharmaceutical, Medical, Actuaries, United Service," shows an advance of 453 per cent.

Notice has been given by the India Office that forty appointments in the Engineer establishment of the Public Works Department in India will shortly be open to public competition, and that a competitive examination will be held in December.

The Boston Town Council contemplate the formation of a public park in that town. The piece of land proposed to be devoted to this purpose adjoins Bath Gardens, and is the property of the Council.

A meeting of the Lexden and Winstree Highway Board was held on Friday last. The first business proceeded to was the election of a surveyor. There were forty-seven candidates. After reading the testimonials, five candidates were chosen from this number, for the purpose of making the final selection. These five candidates were:—Mr. John A. Blenkarne, of 181, High-street, Camden Town; Mr. William Adney, The Grove, Wellington, Shropshire; Mr. Francis Green, C.E., Bridge-street, Hereford; Mr. Robert Wrightson, of Westminster; and Mr. John Richards, of Derby. The voting of the members of the Board was then taken, with the following results:—Richards, 30; Blenkarne, 2; none of the other candidates receiving any votes. Mr. Richards was therefore declared duly elected.

On Wednesday, at the meeting of the Liverpool Town Council, it was resolved that an additional sum of £150,000, as provided by the Act of 1865, should be borrowed, for the purpose of improving the public parks of Liverpool.

From early times the Americans have had nicknames for their chief cities. New York is called Gotham; Boston, the Modern Athens—though it is now oftener called by a name Dr. Holmes gave it, "The Hub," *i.e.*, of Creation); Philadelphia is the Quaker City; Baltimore, the Monumental City; Cincinnati, the Queen City; New Orleans, the Crescent City; Washington, the City of Magnificent Distances; New Haven, the Elm City. The fashion is kept up with the new cities that are built in the West. Chicago is now called the Garden City; Detroit, the City of the Straits; Cleveland, the Forest City; Pittsburgh, the Smoky City; Indianapolis, the Railroad City; St. Louis, the Mound City; Keokuk, the Gate City; Louisville, the Falls City; Nashville, the City of Rocks; Hannibal, the Bluff City; Quincy, the Model City; Alexandria, the Delta City.

In St. Louis there is an establishment for making mantels, &c., from silicate and sand. Flint (silicic acid) and soda are melted together in such proportion as to make a viscid substance. This, mixed with sand, is ground in a mill and becomes plaster-like putty. It is then pressed into moulds by hand. In a few hours it becomes perfectly hard, and is said to be as perfect as the carver's work of months. It is Ransome's process imperfectly carried out.

The Poplar Board of Works have completed the purchase of the new recreation ground in the East India Dock-road from the Secretary of State for India. The purchase money was £10,150. The Poplar District Board of Works had paid £5,418 13s. 10d. on account, and the Metropolitan Board of Works have now come forward with a contribution of £6,000.

Dr. Wagner has made known a simple plan for the manufacture of bricks almost entirely of ashes and coke. The coke, after being broken into very small pieces, is mixed with the ashes, and then with one-tenth their weight of slaked lime and enough water to work them well together into a plastic mass. After standing a day the mixture is moulded into the required shapes. They are set on planks to harden, which they must not be allowed to do too rapidly. They are generally ready for use in about fourteen days.

A swarm of bees lately settled in the roof of a church in Norfolk, where they remained undisturbed till Thursday week, when the parish clerk removed from the roof no less than a hundredweight of honey.

The Committee of the Birmingham School of Design have availed themselves of an offer made some time since by Mr. Cole, C.B., to send a selection of art manufactures from the South Kensington Museum, and the exhibition will open on Monday next in the Fine Art Gallery, Ratcliff-place.

"St. Pauls" of this month speaks rather dogmatically of English architecture, as follows:—"There never has been any style with a just claim to be called English. Architecture, in middle-aged and modern Europe, has been a thing of periods, not of nations. There has undoubtedly been in each country a smack of the soil, giving to the buildings of each a character more or less distinctive; in the most widely differing examples in various countries showing difference enough to constitute (say) a variety, not a species; and in the most nearly alike showing little or none. And this holds quite as good with so-called Classic as with so-called Gothic. If nationality is to be the ground of choice, the Elizabethan style has as strong a claim as any other; but it may be taken for granted that its claim will find no supporters. Though, vicious as this style is, it is doubtful whether its adoption would not, on grounds which will presently appear, involve a less absurdity than would that of any one of the lately exhibited designs. To try to beg the question by speaking of Gothic as English is either ignorant or disingenuous; and, indeed, the attempt is particularly out of place, seeing that most of the designs have a good deal of continental character."

For a single house in the Rue Richelieu, Paris, at the corner of the Rue Ménars, about to be demolished for one of the new streets leading from the Grand Opera, a jury has awarded 2,600,000f., or £104,000. In 1816, the same house was sold for 20,000f.

Patents for Inventions

CONNECTED WITH THE BUILDING TRADE.

3580 J. STANFIELD. IMPROVEMENTS IN THE APPLICATION OF HYDROGEN GAS TO THE FURNACES OF STEAM ENGINES, BOILERS, AND KILNS FOR THE MANUFACTURE OF LIME AND BRICKS. Dated December 16, 1867.

This invention consists in the means of and apparatus for obtaining and applying hydrogen gas to the furnaces of steam engines, boilers, and kilns for the manufacture of bricks and lime, and to this end the patentee constructs the said furnaces with a suitable chamber of any convenient shape, and placed in any convenient position, through which chambers he passes steam, causing it thereby to be decomposed, and thus supply hydrogen gas to the furnaces. —Patent completed.

3591 W. E. NEWTON. AN IMPROVED METHOD OF, AND APPARATUS FOR, THE MANUFACTURE OF TINNED LEAD PIPES. (A communication.) Dated December 17, 1867.

Here a cylindrical casting of lead is first prepared of the requisite size and thickness; a mandril is then placed in the centre of this casting in such a way that there shall be left an annular space round the mandril and between the mandril and the inner side of the leaden cylinder. Into this annular space molten tin is run to form the internal coating. The cylinder or tube thus prepared is then submitted to the action of a hydraulic press, which forces the metal out in the form of a lead pipe lined with tin and rolls it up in a coil in the manner that ordinary leaden pipes are coiled when manufactured by hydraulic pressure. —Patent completed.

3583 T. V. MACKINTOSH. IMPROVEMENTS IN MACHINES FOR MAKING DRAINS OR TRENCHES. Dated December 17, 1867.

This invention consists, principally, in combining a series of digging lines or blades for loosening the earth with an endless chain of dredging scoops which elevate the loosened earth upon a shoot arranged to deliver it either to one or to both sides of the trench or upon a waggon.—Patent completed.

3501 H. BESSEMER. IMPROVEMENTS IN THE MANUFACTURE OF FIRE-BRICKS, TILES, ETC. Dated December 9, 1867.

The patentee claims, first, the manufacture of fire bricks, tiles, and solid or hollow fire lumps, retorts, pipes, crucibles, and other hollow vessels or moulds required to resist heat, by moulding or forming such articles in granulated burned clay, or in a mixture of clay and other materials that have been previously subjected to a red heat, and causing such granulated materials to cohere by the employment of a soluble silicate acted on by chloride of calcium, in the manner described. Second, the manufacture of ornamental bricks, tiles, quarries, trusses, bases, vases, busts, figures, columns, capitals, bases, cornices, copings, tablets, finials, and other articles of a similar character employed in building and architectural decorations, by moulding or forming such articles in granulated burned clay, or in a mixture of clay and other materials that have previously been subjected to a red heat, and causing such granulated materials to cohere by the employment of a soluble silicate acted on by chloride of calcium in the manner described.—Patent completed.

3636 J. CAPPER. IMPROVEMENTS IN THE CONSTRUCTION OF CHIMNEY TOPS OR CAPS. Dated December 28, 1867.

Here the inventor fits within and attaches to a chimney top or cap of cylindrical or other desired form a hollow, conical, or other tapering piece or passage called a "draught jet." This draught jet is open at bottom and top, the end of the smallest area being uppermost, and situated below the upper termination of the cylindrical or other part. The smoke is thereby caused to issue from the said draught jet in a protected position at an increased velocity. He surrounds the upper part of a cylindrical or other chimney top or cap by another or outer cylindrical or other top piece of larger size, thereby leaving a space between the two. The outer piece rises higher than the inner. To the inner cylindrical or other piece below the lower end of the outer one he affixes a projecting ring or flange, and to and between the said ring or flange and outer cylinder or piece he attaches dividing pieces, so that a circle of openings at a short distance from each other is left, through which, and up through the space between the inner and outer pieces, a current of air rises and assists egress of the smoke from the inner piece into the atmosphere. He also constructs chimney tops or caps of a combination of the improvements described under the above first and second heads; and, further, he uses in combination the improvement described under the first head with the outer piece described under the second head, but without the projecting ring or flange and circle of openings therein described.—Patent abandoned.

Trade News.

TENDERS.

ERRATUM.—In the list of tenders of August 21, Mr. D. Cubitt Nicholls is described as architect for "building Foundry Wharf, Wapping for Messrs Innes, Brothers, and Co." This is not correct. Mr. R. B. Marsh is the architect; Mr. Nicholls only prepared the quantities.

LONDON.—For rebuilding No. 5, Fashion-street, Spitalfields. Mr. H. H. Collins, architect:—

A. Cohen.....£320

BRIGHTON.—For building stables, &c., at Wellington villas, for H. Tester, Esq. Goulty and Gibbins, architects, London and Brighton. Quantities supplied by J. C. Lansdown and Co:—

Cheeseman	£504
Hall	497
Nash	471
Lockyer (accepted)	410

BURSLEM.—For repairing damage caused by fire at Messrs. Cork, Edge, and Malkin's manufactory:—

		Additional if fireproof floors.
Blackhurst	£523 15 0 ...	£212 4 0
Barlow	500 0 0 ...	200 0 0
Bowden	495 0 0 ...	206 10 0
Woolrich	493 0 0 ...	320 0 0
Watkin	478 0 0 ...	210 0 0
Bennett and Cooke	475 0 0 ...	249 0 0
Brindley and Critchlow (accepted)	460 0 0 ...	210 0 0

CARDIFF.—To pulling down and rebuilding of shop and warerooms for J. B. Hopkins, Angel-street, Cardiff. J. Hartland, architect. Quantities supplied:—

Price	£960
Michelmore	949
Shepton	940
Jones Brothers	890
Lock	889
Seager	800

HAMPSTEAD.—For making roads and sewers on the estate of the Land Company of London (Limited), at Shoot-up-hill lane, Hampstead. Mr. H. G. Haywood, surveyor. Quantities supplied:—

Ennor	£3915
Mowlem and Co.	3714
Hill, Keddell, and Waldram	3707
Nicholson	3470
Pound	3410
Bloomfield	3145
J. Clark	3097
Porter (accepted)	2700

LONDON.—For first portion of new buildings and alterations to Paddington Workhouse. Mr. Thomas R. Parker, architect. Quantities supplied:—

Adamson	4386
Lovett	4280
Wigmore	4130
Temple and Forster	4100
Nutt and Co.	4100
Butt and Son	4090
Crockett	4036
Till	3947
Lee and Gregory	3842
Ellis and Son	3892
Wicks and Banga	3847
Mann	3795
Higgs	3774
Cooper and Cullum	3590
Merrit and Ashby	3535
Palmer	3500
Foale	3400

LONDON.—For rebuilding warehouse, Bury-street, St. Mary Axe. Mr. H. H. Collins, architect:—

King and Sons	£1015
Henshaw	942
Dawes	880
Wall and Russell	822
Stuart and Bennett	670

LONDON.—For erecting additional factories in Lower Kennington-lane for the Patent Silvering Company (Limited). Mr A. Nickerson, architect:—

Ellis	£1800
Clemence	1644
Henshaw	1618
Newman and Mann	1550
Macey (accepted)	1477

WOLSTANTON.—For the erection of new Wesleyan Schools. Mr. Roberts, architect, Trentham:—

Bradbury	£1375
Brindley and Critchlow	1060
Blackhurst	970
Grosvenor	926
Sutton (accepted)	915

COMPETITIONS.

INDIA.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

HEREFORDSHIRE COUNTY AND CITY ASYLUM.—September 14.—For the erection of the above named building R. Griffiths, architect, 3, Martin-street, Stafford.

ALDERSHOT.—September 15.—For the erection of a billiard room at the Royal Artillery barracks. Royal Engineer office, Aldershot.

METROPOLITAN BOARD OF WORKS.—September 24.—For constructing and maintaining in repair certain intended brick sewers. J. Pollard, clerk, Spring-gardens.

OXFORD-ROAD, MANCHESTER.—For the erection of a new catholic church. J. A. Hansom, architect.

BURTON-ON-TRENT.—September 12.—For alterations and additions to police station. R. Griffiths, architect, 3, Martin street, Stafford.

HIGHGATE.—September 30.—For the erection of an infirmary at Highgate. J. Moore, clerk, vestryhall, St. Pancras.

LEAVESDEN WOODSIDE (near Watford).—September 30.—For the erection of schools. J. Moore, clerk, vestry hall, St. Pancras.

TEIGNMOUTH, DEVON.—For the erection of a coast guard station. Drawings, &c., at coast guard watch room. Tenders to the Admiralty coast guard office.

BOARD OF WORKS, LIMEHOUSE DISTRICT.—September 14.—For watering, scavenging, and removal of dust. T. W. Ratcliffe, clerk to the board.

WEST HAM UNION.—September 23.—For the erection of an apparatus capable of cooking for 800 inmates. F. E. Hilliary, clerk to the guardians, Leytonstone.

LUTON, NEAR CHATHAM.—September 12.—For sinking wells or shafts, and for excavating galleries or headings, in the chalk. S. M. Heckford, secretary, Brompton Waterworks Company, 3, Military-road, Chatham.

METROPOLITAN BOARD OF WORKS.—September 29.—For the erection of fire brigade stations at Amhurst-road, Hackney, and Upper Tooting. J. Pollard, clerk to the board, Spring Gardens.

COLOGNE WATER WORKS.—September 18.—For the supply and erection of high service reservoir, two Cornish steam engines, steam boilers, likewise for cast-iron pipes, cocks, &c. At the office of the Chief Burgomaster.

MANCHESTER.—For erecting a new Catholic church, Oxford-road. T. A. Hansom, 25, Alfred-place, Thurloe square, London, S.W.

STRATFORD.—September 23.—For the erection of a store in Maryland-street. H. Ough, architect, 29, Charing Cross.

SOUTHWARK.—September 14.—For the erection of five houses in St. George's-road. Mr. H. S. Legg, architect, 32, Bedford-row.

PETERCHURCH (Herefordshire).—September 12.—For the reparation of the chancel of Peterchurch Church. T. E. Williams, architect, 67, Victoria-street, London, S.W.

PHŒNIX GAS COMPANY, BANKSIDE.—September 9.—For constructing certain timber and tile roofing. J. A. Crookenden, secretary, 70, Bankside, S. E.

PETERBOROUGH.—September 26.—For the erection of a new Baptist Chapel. J. W. Chapman, architect, 14, Great Western-terrace, Westbourne Park, London W.

EASTBOURNE (Sussex).—September 16.—For the erection of Christchurch district schools. H. E. Rumbles, architect.

BROMPTON, &c.—September 12.—For sinking wells or shafts, and excavating galleries or headings, in the chalk, near Chatham. S. A Heckford, secretary, the Brompton, &c., Waterworks Offices, 3, Military-road, Chatham.

PROPERTY SALES.

AUGUST. 25.

AT THE MART.—By Messrs. Gadsden, Ellis, and Scorer.—One half of a moiety of freehold premises, No. 31, Oxenham street, Coventry street, Piccadilly—sold for £200.

One half of a moiety of freehold premises, No. 32, Oxenham street, aforesaid—£180.

One half of a moiety of freehold premises, No. 27, Coventry street—£520.

One half of a moiety of freehold premises, Nos. 28 and 29, Coventry street—£820.

One half of a moiety of freehold premises, Nos. 30 and 30½, Coventry street—£1,050.

One half of a moiety of freehold premises, No. 31, Coventry street—£450.

One half of a moiety of freehold premises, No. 32, Coventry street—£1,000.

One half of a moiety of freehold premises, No. 65, Princes street, Coventry street—£330.

One half of a moiety of freehold premises, No. 66, Princes street, Coventry street—£340.

One half of a moiety of freehold premises, No. 67, Princes street, Coventry street—£420.

One half of a moiety of freehold premises, No. 68, Princes street, Coventry street—£300.

By Mr. T. J. Tobin.—Freehold residence and nine acres of land in the parish of Hewetsfield, Gloucester—£690.

Freehold residence and six acres of land situate as above—£295.

By Mr. E. White.—Leasehold six residences, Nos. 1 to 6, Albert villas, The Drive, Enmore Park, South Norwood, term 71 years unexpired, at £5 5s. each per annum—£190 and £200 each.

By Mr. Ward.—Freehold two houses, Nos. 59, Hyde road, and 1, Harvey street, Hoxton, annual value £70—£780.

At the London Tavern.—By Messrs. F. R. and F. Vigers.—Freehold house and shop, No. 231, Blackfriars road—£1,180.

Freehold house and shop, with land in the rear, No. 232, Blackfriars road—£1,040.

Freehold house and plot of land in the rear, No. 236, Blackfriars road—£1,080.

Freehold plot of building land, situate in Surrey row—£1,160.

Freehold plot of land, fronting the Camberwell New road—£270.

Freehold plot of land, fronting the Knatchbull road, Camberwell—£320.

Freehold house and shop, with yard and buildings in the rear, No. 4, Lothian terrace, Cold Harbour lane, Brixton, and a lease for 1,000 years of two half and one whole arches—£1,000.

Freehold messuage and shop, No. 26, New Kent road, let at £37 per annum—£920.

Freehold residence, No. 28, New Kent road, let on lease at £13 per annum—£840.

Freehold residence, No. 30, New Kent road—£920.

Freehold residence, No. 32, New Kent road—£820.

Freehold house, No. 38, New Kent road, let on lease at £8 8s. per annum—£1,060.

Freehold residence, with stabling, No. 128, Walworth-road, and a lease for 1,000 years of three arches—£2,050.

Freehold residences, with stabling and buildings, No. 126, Walworth road, and lease for 1,000 years of three arches—£2,400.

Freehold land and buildings, with frontages in New Kent road and Nile place, area about 13,150 superficial feet, and lease for 1,000 years of six arches—£1,770.

Freehold house and premises, No. 1, Nile place, Wentworth street, New Kent road, let at £39 per annum—£820.

Freehold two messuages, one with shop, Nos. 2 and 3, Wentworth street, New Kent road, let on lease at £4 per annum—£800.

Freehold two messuages, Nos. 4 and 5, Wentworth street, New Kent road, let on lease at £7 per annum—£620.

Freehold messuage, shop, and cottage, No. 6, Weymouth street, and 23, Baker street—£400.

Freehold plot of land, fronting the Elephant and Castle Station—£280.

Freehold two plots of land, fronting the Walworth road, and a lease for 1,000 years of an arch—£960.

Freehold plot of land, cottage, and buildings in Hampton street, Walworth, and a lease for 1,000 years of one arch—£570.

Freehold plot of land, fronting Hampton street, and a lease for 1,000 years of one arch—£300.

Freehold two plots of land, fronting Hampton street, and a lease for 1,000 years of one arch—£360.

Freehold house, No. 3, Hanover street, Walworth, let at £19 4s. per annum—£340.

Freehold plot of land, fronting Hanover street, Walworth—£340.

Freehold house, No. 30, Hanover street, Walworth, let at £19 4s. per annum—£370.

AUGUST 26.

At the Mart.—By Messrs E. Fox and Bousfield. Freehold and copyhold estate, situate at Field heath, Hillingdon, Middlesex, consisting of a residence, with stabling, cottage buildings, and ten acres of meadow land—£2,370.

Leasehold three residences, Nos. 1, 2, and 4, Oakley crescent, City road, producing £157 10s. per annum, term 74 years unexpired, at £26 5s. per annum—£1,500.

Leasehold six houses, with shops, Nos. 1 to 6, Market place, Silchester road, Notting hill, producing £255 per annum, term 99 years from 1866, at £38 12s. per annum—£1,900.

By Mr. G. B. Hilliard.—Copyhold estate, known as "Walden House," Great Tatham, Essex, comprising a house, with stabling, farm buildings, and yards, and about 48a. 0r. 11p. of land—£2,700.

AUGUST 27.

At the Mart.—By Messrs. H. Brown and T. A Roberts.—Leasehold 76a. 3r. 19p. of marsh land in the parish of East Guldeford, Sussex, term 500 years unexpired, at a peppercorn rent—£6,820.

Freehold ground rents of £80 per annum, arising from Nos. 134, 136, 138, and 140, St. Paul's road, Canonbury—£1,685.

By Mr. Newbon.—Leasehold residence, No. 42, Compton road, Canonbury, annual value £65 per annum, term 95 years from 1850, at a peppercorn rent—£725.

Freehold residence, fronting the main road, Hornsey—£700.

Leasehold residence No. 1, Archway villas, Archway road, Upper Holloway, annual value £38, term 93 years unexpired, at £7 per annum—£525.

Leasehold residence, No. 2, Archway villas, Archway road, let at £36 per annum, term and ground rent similar to above—£505.

Leasehold residence, No. 12, Cloudesley street, Islington, let at £50 per annum, term 80 years from 1836, at £8 per annum—£515.

By Mr. Saffell.—Freehold estate, situate in the parish of Upchurch, Kent, comprising about 13¾ acres of land, with residence and buildings—£2,510

Freehold 4a 3r. 2p. of land situate as above—£760.

AUGUST 28.

At the Mart.—By Messrs. Rushworth, Abbott, and Co.—Life interest on a Baronet, age 30 years, in freehold estates in the Borough Fen and in the parishes of Newborough, Crowland, and Deeping St. James, in the counties of Northampton and Lincoln, comprising upwards of 3,110 acres, with farm houses, buildings, and six cottages, the whole producing nearly £7,200 per annum—£9,200.

Leasehold four houses, Nos. 23 to 26, Edward street, Blackfriars road, producing £111 16s. per annum, term 16 years unexpired, at £8 8s. per annum—£385.

Leasehold three houses, Nos. 69 to 71, New street, Princes road, Lambeth, producing £46 16s. per annum, term 11½ years unexpired, at £9 9s. per annum—£95.

By Mr. J Apps.—Freehold 8a. 0r. 39p. of hop and arable land, in the parish of Gondhurst, Kent—£700.

Freehold 4a. 1r. 22p. of meadow land, situate as above—£710.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

John William Crook, Langley, Bucks, carpenter, September 16, at 12.—Thomas Lane, Watford, builder, September 11, at 1.—William Joseph Bowen, Tottenham, builder, September 11, at 1—James Cobden, Pooles Park, Seven Sisters road, builder, September 11, at 11.—Thomas Fergusson, Amberly road, Paddington, contractor, September 10, at 11.

TO SURRENDER IN THE COUNTRY.

Miles Ogg, Flaxley, Gloucestershire, carpenter, September 14, at 11—Charles Noble, Bramham, Yorksbire, builder, September 14, at 10.—Benjamin Horsfield Sykes, Altofts, Yorkshire, bricklayer, September 12, at 11.—Gabriel Baker, Bristol, painter, September 11, at 12.—Thomas Hughes, Pontblyddyn, Flintshire, builder, September 16, at 12.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

October 1, J. George, Orleton, Herefordshire, carpenter.—October 17, J. Knott, Coombe, Cornwall, mason.—November 27, H. Cridland, York road, Battersea, plasterer.—September 16, G. B. and G. Capes, Burton-upon-Trent, engineers.

DIVIDEND.

September 11, D. G. F. Macdonald, Brighton, surveyor.

SCOTCH SEQUESTRATION.

John M'Gregor, Dunoon, joiner, September 1, at 12.

PARTNERSHIPS DISSOLVED.

Hedley and Sutherland, Tench street, Wapping, carpenters—Walker and Co., Rugby, and South Wharf, Paddington, lime and cement merchants.

THE BUILDING NEWS.

LONDON, FRIDAY, SEPTEMBER 11, 1868.

PUBLICATIONS ON ENGLISH ARCHITECTURAL ANTIQUITIES.

SINCE the days of Augustus Pugin the character of architectural publications having reference to ancient buildings has not improved, nor has the example worthily set by that excellent and industrious draughtsman been followed with equal zeal. The fact is, that the work to him was a profession, whereas at the present time it is looked upon rather as a pastime to occupy the vacation hours of established architects, or a stepping-stone to reputation by younger men just entering professional life; and it is laid aside as soon as their time becomes more profitably engaged. It is lamentably true that to architecture and all that appertains to it the public may be considered as profoundly indifferent, and that publishers find no sale for such works except among the fraternity of architects themselves. Under these circumstances we must accept the situation and seek only such ameliorations of the system as can be wrought within it. We think, however, that those architects and students who do approach the task do not sufficiently realise what the real need is in the matter.

In the early days of the revival of the taste for mediæval architecture, such a work as Pugin's "Specimens of Gothic Architecture" (1823) was undoubtedly well-conceived and likely to be useful. Yet the later works by that author, in which he was assisted by his son A. W. Pugin, were preferable in many respects. Their "Examples of Gothic Architecture" (1831, &c.) treated of less fragmentary portions of buildings, and dealt with structures of an earlier and better type, many of which were set forth therein with a commendable completeness.

The Brothers Raphael and J. Arthur Brandon, in 1860, published their admirable "Analysis of Gothic Architecture," while "Details of Gothic Architecture," by James K. Colling, equally excellent, had been commenced in 1852; and these careful works supplied the profession with an ample store of precedents, of which it may be said, without any detriment to the authors or their purpose, that it may be questioned whether the use that has been made of them has been productive of more good than harm. Unthinking copyists have taken advantage of them, and brought ridicule not only on themselves but upon the whole school of the revival by the manner in which they have malappropriated instead of studied the various details which are given in them.

"The Examples of Ancient Domestic Architecture," by F. T. Dollman and J. R. Jobbins (1858, &c.), is a work of a different and we think a far more useful character. It transmits a thorough and faithful record of most of the interesting old buildings selected for illustration, and though, of course, it is open to misuse and piracy, as we might term the wholesale importation of any feature from the work of a past age into modern building, it in no way lends itself to such a practice.

The magnificent work on the principal English abbeys, entitled "Architectural Parallels," by Edmund Sharpe (1845), had a higher aim than any which preceded it, nor did the manner of its execution fall far short of its aim; but, for completeness in the manner in which the fine examples of English ecclesiastical architecture selected are represented we know few works to equal that on "The Churches of the Middle Ages," by Messrs. Bowman and Crowther. The somewhat scarce works on Wenlock, Buildwas, and Tintern Abbeys, by Joseph Potter, also merit very high praise.

In the production of such works as these, and some few others of the same class, the list of which our limits prevent us from pretending to make exhaustive, there seems of late years to have been a comparative cessation.

Another style of architectural publication has since come into vogue; it is that fitly described by their authors as consisting of *sketches*. They are results of tours undertaken by architectural students, and are interesting and valuable enough in their way, but from their very attractiveness are liable to lead away the younger professional men from the class of study which would be more beneficial to them. In these we have few if any measured drawings, the making of which is the staple food upon which young architects should be brought up, and picturesque pretty drawings are their object throughout.

It is true that in noticing these we are somewhat straying from our subject of *English* rather than *foreign* architectural publications, but their authors, the foremost among the professional students of their day, chose the continent instead of their native land as the theatre of their studies, so that we are forced, as it were, to follow in their steps, protesting meanwhile that their choice is not the one we would wish accepted as a desirable precedent.

The first, and by no means the least able, was that by Mr. R. Norman Shaw, entitled "Architectural Sketches from the Continent" (1858). They are dedicated to the members of the Royal Academy, having been taken in his capacity as travelling student of that institution—in itself an ample reason for the transpontine localities from which his subjects are taken. Through France, Lower Germany, and Italy the succession of his pages hurries us, giving us glimpses—glorious glimpses—of the noble buildings he met with in his route, just as a literary bee might of the scents of the various flowers she rifles with scarce greater rapidity. Of this work we notice that the author says in his preface that he hopes its chief utility may be found in its *suggestive tendency*. We know not what hard fate drove him at such a pace on his travels, and can, therefore, only pity him as we should the mad dog whose last fatal course was urged to unwonted speed by the kettle tied to his caudal appendage. But if it were from exigencies imposed by the Academy we should have much to say on the subject, being of opinion that it would be far better for its students to bring home thoroughly well-studied drawings of one good building than even able sketches only of the whole in Christendom. We assume, however, that the *suggestive tendency* coveted by Mr. Shaw for his sketches was not exactly that others should go and do likewise.

We find, however, in 1862, another equally able and equally discursive set of "Specimens of Mediæval Architecture, chiefly selected from examples of the twelfth and thirteenth centuries in France and Italy, and drawn by W. Eden Nesfield," in which measured drawings to scale form a still smaller proportion. Of this work, as of the last, conceding the aim to be one of the bee order, highly to be desired that it should be taken by some, it would be difficult to surpass them in the excellence and spirited manner of their execution.

We have now, however, before us, just completed, another volume of "Detail Drawings and Sketches in England and France," by F. Rogers, which is not quite so able, while it is even far more discursive than either of its predecessors. In its license of choice the butterfly rather than the bee would appear to have been the type followed. Cathedrals, churches, houses, cottages, and chests are wandered among with a sweet free will. Now, were a sculptor to publish a parallel work we should be danced from ancient Egypt and classic Greece to the France of Francois I. and Louis XIV., be presented in successive pages with the Apollo Belvedere and a Nineveite bull, with the Venus di Medici and an Attic steed, the nose of a Hercules and leg of a Satyr, and we should close its pages with very much the same impression left by an afternoon's walk through the Crystal Palace.

Lest we should seem to exaggerate, let us suppose an architectural student, of the non-roaming order, seeking in the three works referred to for some information as to Chartres Cathedral. From Mr. Shaw he would only get, in plate sixteen, the elevation and details of a miserable little doorway, on the north side of the clock turret, of which the only speciality is the introduction into the jambs of two columns for their own sake and nothing else, as they have nothing whatever to support the head—a simply chamfered lintel—so that they are dragged in, neck and shoulders, into conversation, as Sampson was. In Mr. Nesfield's book we get the two west spires, but disconnected. The tympanum of one west doorway, two capitals, and a base, and two scraps of friezes from the celebrated north porch; while, in Mr. Rogers's book we get a lop-sided view of the north-west angle of the north portal, and such a miscellaneous number of scraps, from various parts, that they look as if they were studies in an old curiosity shop.

Now with hearty and sincere thanks for the many objects of interest these authors have given to us, we would say, to future students, that of such fragmentary sketches we have had quite if not more than enough. Our head aches with the difficulties of searching in these volumes for what we happen to have wanted, and our powers of memory would fail us if the number of this sketching band were much further enlarged.

Far different is the work since published by Mr. R. J. Johnson, upon "Early French Architecture." This is one of which it is impossible to speak in terms of too high praise. It is nearly exhaustive of what it proposes to treat, and its style of execution is first-rate.

We wish, however, that our architects and architectural students would look more at home. French architecture, by French architects and Government aid, has been, on the whole, very fairly and fully represented, and we may well leave the completion of that task in their hands. But English architecture has been but fragmentarily and indifferently put before the world, and its reputation has suffered accordingly.

Where are any monographs of our Cathedrals? Where are any details of them given on an intelligible scale and in a reliable manner? What is there to give a foreigner a clear idea of any of the masterpieces of our special insular styles—the Early English or Perpendicular? Where are our countless admirable parish churches and noble towers and spires reliably set forth? Sketchily, and in a picturesque manner, many may be seen in the "Reliques of Ancient English Architecture," by John Johnson, and others in Brandon's "Parish Churches;" but these works only serve to indicate a mine of wealth, of which they do not more than pretend to skim the surface.

In the meantime the rage for the restoration of these buildings is proceeding at such a rate that more than ever is the work of properly delineating our ancient monuments imperatively needed. We hail, therefore, with pleasure, the establishment of the Pugin Studentship, the express purpose of which is to induce young English architects to study and draw the mediæval remains of our own country, and as the first fruit of the movement, and earnest of what we may expect to reap through it, we welcome "Illustrations of the Mediæval Antiquities of the County of Durham," by John Tavenor Perry and Chas. Henman, jun., the former a past Pugin Student, and the latter the present

one. Still we trust that the good work will not merely be left to the junior members of the profession, and venture to suggest, as one method of obtaining the end we have in view, that architects who are engaged professionally in the work of restoration might do good service in publishing the drawings which it is incumbent upon them to have made of the present condition of such buildings of interest as they are called upon to restore.

TOMBS AND TOMBSTONES.

THE word tomb, which strictly means a mass of stonework raised over a grave, is in common use applied to any sepulchral structure. From the earliest ages man has devised some monument to his departed fellow. In the historic ages the most ancient is the rock-hewn tomb, but the *tumulus* is undoubtedly of much higher antiquity, as the rudest people, without implements, could accumulate a large heap of stones and cover it with earth. We are not going into a disquisition as to the comparative antiquity of the subterraneous or Hypogæan, and the above-ground or Hypergæan systems of burying and commemorating the dead. We will pass by the stupendous monuments of remote antiquity, the mausoleum built by Artemesia, that of Hadrian, and the smaller one of Cæcilia Metella, which, however, is 90ft. in diameter and about 130ft. in height, and come at once to a phase of the subject which more nearly concerns ourselves. There are few who would wish to pass away without leaving some sign behind them, and among the very poor this feeling is stronger than among the very rich. The names of the latter cannot well perish. If not matter of history they are matters of record, and however obscure may be the place of burial their memory cannot lightly die; but with the poor it is different—their annals are short and simple, and they look upon some sort of head-stone as a thing of great importance. It might therefore be supposed that in every country a considerable degree of skill had been attained in the production of memorials, but this is far from being the case, and, leaving foreign countries out of the question, let us look at Kensal Green. We take Kensal Green to be a representative cemetery—the burying place of the illustrious, the rich, and the middle classes, the type of public taste in monumental architecture in the middle of the nineteenth century. If anything were wanting to check the notion that we are near the millennium of art, or that we have made any perceptible advance in national taste—in the monumental line, at least—a visit to Kensal Green Cemetery would suffice. It is little to the purpose to say that the French exhibit no more, or the Americans less, taste in this particular; the question is why, with all our vaunted revival, our hosts of ardent spirits—earnest students they call themselves—do we, with the best intentions, put up such vile memorials to the dead? The subject is a delicate one, and we have no desire to wound the feelings of anyone, but private considerations must give way to public welfare, and if anything in these columns should awaken people to the absolute duty of providing memorials of a better character than now prevails, if those who have been respected during their lives should not be made ridiculous in death, we shall be satisfied.

It is not desirable to go deeply into the question of the good taste or propriety of epitaphs. "The heart knoweth its own bitterness," and so long as the epitaph shows feeling and is free from overweening confidence, or, as sometimes happens, a defiant spirit, the passer-by has no reason to complain. When, however, after the address, *siste viator*, we are told that the lady of John Smith was "the best of wives," it is impossible to overlook the fact that the majority of married men in the world might be unwilling to acquiesce in John Smith's complacent view of his good fortune. With exceptions such as these, epitaphs should not be criticised, but the mere monument, as the work of an artist or worker in stone, is legitimate subject for comment. The public by no means oblige relatives to erect memorials to the deceased, but they have a right to expect them to be inoffensive to the eye, and unopposed to the general fitness of things. It can never be maintained that stone scrolls and draped urns are elegant, or that sarcophagi like cellarets, columns wreathed with roses, obelisks terminating in heaven-pointing hands, or broken lilies symbolising the decease of a middle-aged person, are appropriate; but in the span-new monuments we see less negative beauty and more positive pretension. The lavish employment of polished granite, particularly red granite, of marble called Sicilian, serpentine, Irish green, and Derby marbles, encaustic tiles, orbs of coloured glass, and, above all, the use of gilding, is destructive of repose and the modest simplicity of what the Italians call a Holy Field, and the Germans God's Acre. Equally out of place is the excessive use of bright-coloured flowers. A cemetery is not a tea garden, and, although there is no need for us to "enhance the gloomy horrors of the tomb" by excluding all the grace that flowers and foliage afford, still such plants and trees should be chosen as are "fitt to adorne the dead and deck the drery toombe." Any white, blue, neutral-coloured, or purple flower is appropriate, but yellow, red, or any mixtures of the two last colours are unsuitable. In the choice of trees and shrubs there are few that must be excluded. Forest trees scarcely find a place in most cemeteries on account of the space they require, and it would, therefore, be better to leave the horse chestnut out of the list and to be sparing of weeping willows. Deodar cedars are very well as long as they are young, but when full grown they require as much room as others. It is rather to shrubs, large and small, that the gardener should look for the embellishment of a cemetery, and of these so many are fit that it is needless to name them. Of all places in a cemetery a grave is the last on which flowers or shrubs should be planted. The common practice of turning the grave itself into a little garden is most objectionable. A flat or a coped tombstone, or *dos d'ane* as it is called, or turf, is the only proper covering for a grave. With a monument the case is different, as it by no means implies that the body is buried beneath; but a mere head and foot stone, with a raised curb, enclosing a few geraniums, or, perhaps, two or three dwarf arbor vitæ, is open to objections that are more than sentimental. The profuse use of flowers of brilliant colours is much to be regretted. Round one grave, a large one, are set no less than twenty-four geraniums in pots. In contradistinction to this monument may be seen one erected about twenty years ago to Mr. H. Webb, of great simplicity and grace. The style is Pagan, but it is not paltry, like too many of its neighbours erected within a year or two. One of these consists of four square legs of serpentine marble, supporting a slab of the same material covered by a slab of white marble. The whole looks like a small but heavily-mounted billiard table with the white cloth over it. A monument of more than ordinary pretensions—that to Captain Rickets—is in every respect a remarkable work, and has only recently been completed. It is a sort of shrine, supported by eight external columns of red granite and twelve dwarf columns of Irish green marble, the latter supporting a stone cist. A canopy, with crockets, gargoyles, and finials, crowns all. The style is French Gothic of the thirteenth century, and the monument is well worth seeing. The mortuary chapel, if it can so be termed, of General Perry, merits attention on account of its beautiful metal doors, but it is not elegant in general form. The vault of Mr. A. Blumbery, of white marble and polished grey granite, in the form of a Grecian temple, about 15ft. square, is just finished. It will look better when the polish has gone off. Here will be seen what we believe to be the only terra cotta monument in the cemetery. It is erected to Mulready, the genial, well-beloved painter. The effigy of the deceased is recumbent under a canopy supported by six columns, the whole in terra cotta. In panels in the sides of the dado, rough sketches of some of his principal works are incised. This monument is worthy the attention of the student, from its original treatment, but it is very questionable whether such a treatment is suited to the open air. In a church it would be proper, no doubt. The large granite tomb of Sir W. Molesworth is remarkable for the injudicious manner in which the descending steps are contrived, but it is simple, and so far meritorious. Of very opposite character is an ambitious octagonal structure of white marble and red granite, of enormous size, in memory of Mr. H. Molyneux. We question whether in modern times any private individual in any country has so large and costly a memorial. There is nothing to compare with it in the cemetery in this respect, but it is in indifferent taste, and is not an improvement on the memorial art of thirty years ago. The plain grey granite vault of General Duncan Sim is in better taste and far handsomer, great judgment being shown in polishing certain of the surfaces only. The monument of the Ducrow family is too well known to need comment. Passing by the monument of J. St. John Long, by that almost universal genius Sievier, the gigantic granite slab which covers the vault of the Rashleigh family is conspicuous, as also the metal plate whereon are engraved the names of the deceased. The student will see that this treatment is massive, but by no means elegant, but far better than the glittering white marble, incised with patterns, tile-bedecked, and jewelled, which is in abundance on every hand. The memorial of J. Meadows Kendel, of unpolished red granite, and the wrought-iron one of Mr. T. Walford, are the next objects of interest. The latter is a decided failure. The pretty little Doric temple which contains the remains of Dr. Valpy will be noticed for its classic elegance, and the monuments of the Princess Sophia and the Duke of Sussex for any merit the student may suppose them to possess. The monument to the former, though consisting principally of a sarcophagus raised high in the air, is not inelegant. There are few persons at present living who could design a better in the same style. The recently-erected tomb of Sir de Lacy Evans is no improvement on the work of the commencement of this century. In this portion of the cemetery there is little more that is worthy of notice. The usual amount of uninteresting headstones, broken columns, weeping willows, and lachrymatory urns will be found, and perhaps a few Gothic crosses and slabs in no way remarkable. The stranger returning to the entrance will wonder what palm branches and wreaths of bay have to do with Sarah, the beloved wife of Mr. Green, as he never heard of her as a poetess or even a martyr. But he will feel that on Robert Lindley's humble tomb the violin unstrung and broken is neither ill conceived nor badly executed.

Ascending the hill the Catholic cemetery is reached, and from the well-known mediæval predilections of that religious body it might be expected that some tasteful crosses or mortuary chapels would be found. This is not the case. Of the former there is scarcely one, and of the latter none whatever. A small unfinished building roofed with gaudy red, green, and black glazed tiles glittering in the sun, and a still smaller building of no pretensions, are all that meet the eye.

Now it is well known that there are some excellent architects of this persuasion, men admirably qualified to supply the very thing

which is wanting, a monument of a religious rather than sentimental character, but of their existence this cemetery presents small traces. The plain coped stone, surmounted by a foliated cross, in low relief, with the inscription on the bevelled plinth, is almost unknown, and yet it is the most appropriate covering for a single grave. The headstone, usually in the form of a foliated cross, seems to be the favourite; but we noticed no monument that seemed worthy of the present state of Gothic art. We, however, saw more than one that showed the affection in which the dead are held. In the southern portion of the cemetery the poorest of the poor find their resting place. Here there are hundreds of graves, distinguished by little plaster casts of devotional subjects, beloved perhaps in life by the sleeper below the earth, for sod it cannot be called at present. In one case about twenty white stones, weighing nearly three pounds each, were placed side by side, from the head to the foot of a grave, that had nothing else to mark it. In another case, the only sign was a flint stone about 6in. square, placed at the head. This mourner was poor, but offered all he had, and his offering, rude as it might be, was not in bad taste; but how with the others of ample means? The subject is depressing. It is humiliating to find that country or creed makes little difference in the bad taste and low art prevailing in monumental works, and in this country our shortcomings are the more to be deplored from the high state of civilisation to which we are always assuring ourselves we have attained. The remedy lies in our own hands. If the architect, artist, and sculptor are employed more and the cemetery mason less, there is no reason to doubt that in ten years as great an improvement will be made as has been effected in a like period in any branch of art. But we repeat, the art must be in higher hands than it is at present, and money should be spent in obtaining a pure design, and not in florid and often absurd decoration.

WESTMINSTER ABBEY AND ITS ORGAN.

IT has often been said by the leading journal that if we English people are not remarkable for "commerce and business" activity, we are assuredly remarkable for nothing else, and no one will, I presume, be at all likely to dissent from this somewhat severe dictum, though it does not say much for us. It is not *fine art*, certainly, that we are now in this present age remarkable for; there are no great and enduring paintings nowadays, and in this country, in process of execution; no work of sculpture other than manufactured; and the great work of the future, says the same world-wide authority, must be the "rebuilding of this hideous metropolis"—mighty London; so that there is nothing, it would seem, but business and business only.

Mr. Disraeli, who has achieved so much in so very many ways, is even more severe than this, and once declared that the whole modern world, generally, and everywhere, could not consider itself famous for anything whatever in these modern times but *music*—*i.e.*, musical composition and musical performance. Indeed, he says, what sculpture was to the Greek, and architecture to the Egyptian, *music* is to us—not, perhaps, to England, but generally to the modern world. And to cite another great authority, Mr. Hullah, nothing has made such progress as modern musical instrument-making. But volumes of poetry, says he, have been written about the antique lyre, but who ever saw a line on the subject of the infinitely finer but common-named fiddle? In spite of the *Times* dictum, therefore, we are improving, fiddles are improving—at least they say so—and so are *organs*, church and cathedral organs.

Westminster itself, as everybody knows, is all of it in a rapid and truly cheering course of systematic improvement—streets, drainage, houses, and all; and the venerable Abbey itself could hardly be expected to fall behind in such a race of progress on to ultimate perfection, and a very great deal might be said about it and its old and its new arrangements, so suitable to modern wants and requirements, and ritual! But our immediate and pressing object now is the Abbey organ, which is under a thorough course of cleaning and repairs and "additions," and we would therefore most respectfully ask a little attention to it, so that it may be seen what it is possible to do in these days of universal improvement and educational excitement.

It is first necessary that the reader should at least roughly understand what an organ is. It is not a simple instrument, like a pianoforte, all before you at a glance; but a large organ like that at the Abbey is a very complicated instrument indeed, and is in reality not one simple instrument, but several—*i.e.*, a quoir organ, the great organ, a swell organ, and so on, each consisting of some hundreds of pipes, and many *ranges* of pipes or stops, and working apparatus. Of course it is impossible to describe all this, but anyone will be able to understand, without lengthened description in detail, what a very complicated piece of apparatus it is. It must, however, be understood that though the whole instrument is made up of many parts, it is in fact *one* instrument. It is necessary to be studious of brevity, but without a little particular commonplace description it is not possible to make clear what it is needful to say. I cannot refer at present to the only book likely to give it (Hopkins and Rimbault on the Organ), who I dare say have found out; but it does happen sometimes that a wonderful flash of genius comes across some perhaps humble man engaged in the manufacture of a common piece of mechanism, and this never happened more happily than when the *swell organ*, as it is so well called, was thought of. It is quite an obvious thought, like the way to America, when you have once seen it and know it; it simply consists in shutting the pipes up in a box, with a portion of it so made as to open by louvre boards, so that the sound is shut up or deadened, and let out or *swells*, at the will of the performer, who shuts or opens them at pleasure. Nothing can be simpler or more obvious than this, but it is a splendid triumph of genius both mechanically and musically, and creates, when judiciously managed—which is not always the case, for you can work the best of ideas to death—the most beautiful effect of which music is capable, comparable to nothing but the sound of a sweet-toned bell under the influence of the wind, the purest of sounds. I say that this happy and beautiful thought can be worked to death, but Mr. Turle, the organist of the Abbey, fortunately, is as skilful and happy in the use of the swell organ as it is in itself a skilful and happy thought. It could not be better done, because there is not too much of it—the truest of all tests of the good and proper use of anything. But this is not all. The pipes of an organ nearly all of them stand upright, so that the sound, coming out at the top, goes upward towards the roof, and is reflected down again from the roof and walls. It is important to bear this in mind, and also the fact that the purest of all sound or sounds from a pipe or pipes is *after* the pipe or pipes are closed and have ceased to speak, and the sound is in the air.

Another point to note, and it is quite as important, if not more so, to keep it in mind, is, that it is not the instrument only, but the position it occupies in a building, that determines the quantity and quality of the sound effect it produces; and in our cathedrals, through a series of ages, it must have been a problem where best to put the organ; and the rood screen or organ screen was found to be, as it most surely is, the very best place—the result of the wisdom of our ancestors, for the organ is clear of everything, with plenty of room for the air vibrations, so that the whole organ is as a trumpet in the open air, and there is as much difference between an instrument in such a position and in one shut up in a box (as at the Temple Church) as there is between a trumpet in the open air and one tied up in a coal-sack. Again, a great deal depends upon what the organ stands upon, its solidity, firmness, and so on, and still more on the nature of the material of which the *walls* of the building in which it is are composed, whether of stone or of plaster, and whether *painted* or not. Now there were only three buildings in London wherein might be found all these precious and rare requirements—the Abbey, St. Paul's, and the Temple Church; and it is hardly to be credited that in all three of them all these rare and happy advantages have been ruthlessly sacrificed and thrown away. To confine ourselves for the present to the Abbey. In a truly unfortunate moment it was determined, I presume by the Chapter, under the advice of the Abbey architect, Mr. Scott, that this organ should be *cut in two* or rather three, a large organ on one side, another large organ on the other side, both almost touching the top of the aisle arches, and a small organ, or rather a few pipes, in the middle—I suppose, to hide the performer, and thus in a moment to destroy at one blow the whole strength of the instrument, for now the organist sits in the middle of it, with one half of it behind him, instead of the whole of it before him, giving him thus a certain command over it, which is now lost, to say nothing of the fact of his being entirely hidden from the choir, and they from him. But the final and fatal blunder is this, that the swell organ, so happy in effect, will not act, and this is very curious and well worthy of a little thought. As I tried to explain, the *swell* is produced by the opening and shutting of louvre boards, and in the old arrangement, when the whole organ stood in the middle of the loft, the louvres so opened as to throw the sound into the nave, and there it found space and air to vibrate in, and (so charming was sometimes the effect) to return after reflection, producing a sort of echo from the west wall. It is impossible to over-estimate the value of this beautiful accident, but it has been all thoughtlessly thrown away, no man understanding it or having the courage to say nay to its destruction.

But even this is not all, for it will hardly be credited that the motive given for this stupid blunder—for what else can it be called?—is, that it—the putting the organ out of sight—"opened out the Abbey, and exhibited to greater advantage its Gothic proportions!" Now, I think that every Gothic man may be confidently appealed to for this—that if there be one thing more than another which may be called a "fixed principle" in Gothic architectural plan inventing, it is this, that in a Gothic interior like the Abbey, the screens, altar rails, and "furniture" generally, *add* to the Gothic effect of it, and increase its architectural nobleness. A sort of confusion and mystery is created by your not seeing the whole building at once, like its plan on paper, but yet being clearly conscious of its size and extent. "Opening out," for that is the term, is simply Gothic destroyed. And Professor Willis (description of Canterbury Cathedral) especially notes the miserable mistake that was made when some restoring architect went down there and destroyed all the screens, and fairly gutted the church. Who does not agree with Professor Willis? This, therefore, in addition to the musical destruction, has been repeated in Westminster Abbey, when its organ was cut in two and put out of sight, that you might "see the Abbey!"

Is it too late to amend all this? for that is now the question and the reason of this notice; for, as I have already said, the organ is all to pieces, cleaning and mending, and, what is more, a new "trumpet stop" of very great power (*tuba mirabilis*) is to be added to increase the effect of the organ accompaniment in f. f. passages. Wonderful! Has it ever occurred to anybody connected with this place that the *quoir* is a necessary and very constituent element in the "music" of Westminster? But let us be thankful for all things particularly, and more especially for this *tuba*; and, also, to come down from the sublime to the very ridiculous, for a little attention to the *bellows*, for, truth ought to be told, they make nearly as much noise as the organ itself, in the act of blowing. But, I say, let us be thankful for what we can get, whether much or little; and so now, having got the new trumpet, and well rid of the old one, which some may remember with dismay, let us ask, as the choir boys say, for more—*i.e.*, let us ask Mr. Scott and Dean Stanley to kindly take it into their thoughtful consideration whether or no it would not now be a capital opportunity, after so much mischief, to commence the real and *bonâ fide restoration* of the Abbey Church of Westminster by simply putting back in its proper place "the organ," so that you may both hear it and see it; for what possible, even miraculous, additions can be made to this organ which can possibly make up for the previous total breaking up of the whole instrument into bits, cases, pipes, sound, music, and all—putting all the said bits where they cannot possibly act, destroying the organist's power over the instrument, and so deadening and destroying the quality of the sound from it that I do not hesitate to say that the putting the whole thing out in the Broadway would have been less of an evil?

C. B. A.

GOSSIP FROM GLASGOW.

(FROM OUR CORRESPONDENT.)

AFTER a tedious delay the statue of Lord Clyde has been placed upon its pedestal. From not only the reputation of its sculptor, Foley, of London, but from evidence of his genius, as seen in a model of Burke, lately shown in our Fine Art Exhibition, something great was expected. It is a statue that may "please the million," but I am not sure that it will altogether satisfy the fit few who are versed in not only the canons but the associations of art. The treatment is eminently realistic, and there is a melodramatic, not to say "bumptious," air about it, which is as alien to the highest class of art as it was to the character of the modest-minded soldier whose services it seeks to commemorate. This may perhaps arise in some degree from a slight anachronism. The accessories all indicate the brief but brilliant career in India, while the face and the whole bearing of the statue point to a period fully twenty years earlier. In especially artistic repose Foley's Lord Clyde cannot for a moment be compared with the statue which it has displaced, the Sir John Moore, of Flaxman. However, whatever its defects, I must say this of it, that it is a vast relief from the many Marochettis to which Glasgow has so long been almost invariably doomed.

I had lately an opportunity of seeing a cast of the head of Foley's statue of Lord Clyde. It is (in an art sense) broad, simple, and heroic, and wholly dwarfs the rival busts by Adams and Ewing.

Operations are commenced in converting part of the corporation property in Sauchiehall-street from dwelling houses into premises for the School of Art and several of the scientific and learned societies. It is likely that the Architectural Society will find here a congenial home.

The "Eastern Difficulty" is about as chronic in the deliberations of the Glasgow Town Council as in the politics of the courts of Europe. Whenceever arises the general Oriental grumbling and dissatisfaction, in at least one instance the wise men of the East have long had a real grievance, the inadequacy of their police-office accommodation. Far be it from me to say that there has been a disproportionate increase of crime in the meridian of the Calton. It is more pleasant to find a sufficient and satisfactory reason in the obvious facts that the present prison is wholly unsuited to its purpose, and that it is desirable to have the several departments—now scattered—such as lighting, cleansing, and watching, under one roof, as they are under one administration. Another reason is, that justice, which in such matters is too often blind, required that magisterial dignity should not in the east be "cabined, cribbed, confined" in a dingy den, while in the west it luxuriates in a spacious palace. Within these few years new police offices have been built in the west, north-west, and north-east districts of the city, and now the east in turn has its claims recognised. The western police-office is an exceedingly elaborate building, ornamented with carving and embellished with sculpture; and, had not the east got shortly something decent as a *quid pro quo*, the local jealousy would likely have become incensed, indignation meetings have been held in the City Hall and on the Green, and about half of the town councillors been made to shake in their shoes in which they were to "walk their chalks" at the impending municipal election. The eastern police-office is a much plainer building than is its sister in the west, and depends less for its effect upon elaborate ornamentation than upon breadth of composition and simplicity of detail. It consists of a centre of two stories and two wings of one. The centre is about 80ft. long, and each wing about 40ft. The wings and the basement of centre are rusticated. Above the rustic work is a dado course, and upon this in the centre compartment are set windows having architraves, frieze, and cornice. The centre building is crowned with a noble cornice, unbroken from end to end, and enriched with dentils and modillions The doorpiece, although simple, is effective, and is composed of architraves, frieze, consoles, and cornice. On the frieze is carved the city arms. The architect (also of the western), is Mr. Carrick, the city's master of works.

A new broom sweeps clean, and the new lord of the manure is making a clean sweep of the streets by brushing them by machinery.

Messrs. Bateman and Bazalgette have issued their report upon the sewage of the city. Their proposal is nothing new—to carry it in covered aqueducts to the sterile sands of Ayrshire, and dispose of it as manure.

Whatever a reformed Parliament may do or may not do about education, Glasgow, always forward in this good work—bear witness its normal schools and its printing for the blind!—has been, meanwhile, doing a little in the way of helping itself. In Elgin-street a large building is almost completed for the Gorbals youths' school, and at Mossbank, the other day, the foundation stone was laid of the Glasgow schools of industry. The design for the Gorbals youths' school is by Mr. Honeyman, and, as it is Italian, he seems to be forsaking that first love to which I thought he had been irrevocably wedded—the Gothic. The basement is rusticated, with arched windows, and has a Doric doorpiece of coupled three-quarter columns. The upper storey is somewhat plain, but character is given to it by a bold cantilever cornice of iron and timber. Adjoining there is being erected an ordinary tenement, of a Greeky character, by Mr. Gildard. The architects for the Glasgow industrial schools are Messrs. Douglas and Stevenson, and the style is the Domestic Gothic. This building is to be of red, black, and white brick, will be 240ft. in length, three stories in height, have a spire and dormers breaking the sky-line, and will furnish accommodation for about 1,000 children. These schools are considered of so much social importance that their foundation stone was laid by the Grand Master-Mason of Scotland, the Earl of Dalhousie.

Subscriptions for the Wallace Monument are "never ending, still beginning." Begging circulars having once more been issued, surely the £5,000 which it was to cost will be now speedily raised, and the monument along with it, or else we may ask with Macduff, in *Macbeth*, "Stands Scotland where it did?"

In a recent review of a Glasgow book on architecture you twitted us Scots a little on our partiality for the Greek. We may be right or wrong in our partiality, but we have some reason to be proud our achievements. The High School, the Royal Institution, Surgeons' Hall, and the several monuments on the Calton Hill, in Edinburgh, and the gaol, by Stark, and the later and more original works by Thomson in Glasgow, argue not a little, I think, for a just taste in the north; and in the battle of the styles Greek has just accomplished another rather considerable triumph. I mentioned some time ago a competition for designs for a church, the style being strictly limited to Greek and Gothic. Messrs. Thomson entered Greek, and, notwithstanding all the eloquence that has been expended in enforcing again and again that Gothic is your only style for churches, the Classic conquered. Another competition has been decided since I last wrote to you, that for the Reformed Presbyterian congregation in Cumberland-street. In this case there was no limitation of styles, and the successful design is Gothic, by Mr. Barbour, of Dumfries. This small body of Presbyterians seems to be prospering, if I may judge from it being about to build also in Laundressy-street. This building will be likewise Gothic, and the architect is Mr. Thomas Binnie, a new and hitherto unknown aspirant towards fame and fortune in designing broach spires and pointed arches.

The chief event of the season is likely to be the new offices for the Scottish Widows' Fund Assurance Society, the architects being Mr. Bryce, of Edinburgh, and Mr. Burnet, of Glasgow. The site, a most valuable and imposing one, is being presently cleared out.

Very rapid progress has been made with the building of the University. The eastern wing is already being roofed.

Glasgow, that "flourishes by the preaching of the Word," boasts once more of one of the largest provincial theatres, the Colosseum. The proscenium, although not so wide as is that of Drury-lane or Covent Garden, is said to be deeper than any in London, and this depth is being added to. Beneath the stage is a place 30ft. high, into which scenery descends, and part of which is bridged over for the building of set-scenes, &c. If the Union Railway gets dragged along, the Theatre Royal will shortly require to be rebuilt.

Of country work, a large mansion is being built in the Upper Ward of Lanarkshire, by Mr. Finlay, merchant, from designs by Mr. Leiper (late Melvin and Leiper), a clever young Gothic architect, whose talents have almost all at once given to him a high place in the profession; and in the classic Vale of Leven, overlooking the birthplace of Roderick Random, Mr. Aiken, spirit dealer, is erecting a mansion from designs by Mr. Watt.

Having now probably shown that my long (and enforced) silence was of no great consequence, I lay down my pen, hoping that no such interval may occur until I resume it.

BUILDERS' AND GENERAL HARDWARE.

(FROM A BIRMINGHAM CORRESPONDENT.)

AFTER a depression almost unexampled in its duration and severity, the hardware trades of Birmingham and the great Midland district are beginning to show signs of recovery, and the numberless factories and workshops are once again in tolerably steady operation. Builders' and contractors' ironmongery is in better demand than for two years past, but it is noticeable that the builders in Australia and other colonial markets who used to outbid English builders in regard to the superior quality of their fixtures, are now beginning to prefer cheaper and commoner articles. A good business is being done in the Scotch trade for all kinds of hardware, and the West Indian orders are improving. The East India market is taking a much greater quantity of railway and engineering ironwork than for some months past, but, of course, a large proportion of the present demand is on account of Government contracts. The home trade is steadily improving in all the principal departments, and the factors' travellers predict a fair winter demand, especially for builders' tools and furnishing ironmongery.

In Birmingham, the cut-nail works are in steadier operation, and the demand for wood screws—a trade which is in the hands of two or three firms—is gradually recovering. In the gun trade, the manufacturers still complain of depressed prices, although during the past fortnight the demand for sporting guns has been more favourable. The Birmingham Small Arms Company have just declared a dividend for the past half-year at the rate of 20 per cent. per annum, after carrying the large sum of £6,000 to the reserve fund. Mr. Joseph March has been appointed proofmaster, under the

"Gun-barrel Proof Act, 1868." The salary attached to the office is £600 per annum. Steel pens, buttons, and fancy wares are only in moderate demand. Edge tools and steel toys command a somewhat better inquiry, and some of the metallic bedstead makers have a fuller employment for their workpeople. A well-informed correspondent of the *Builder's Weekly Reporter* states that "the hammer makers still suffer to a considerable extent from the competition of rival manufacturers in the Northern States of America, whose productions are increasing in favour among the builders in this country." A tolerable home trade, however, still remains to the English hammermakers, who will doubtless be stimulated to greater enterprise by the influence of a little wholesome rivalry.

At Wolverhampton, the makers of galvanised ironware are a shade busier, notwithstanding the great increase in the production of such ware in this locality during the past few years. The lock trade is tolerably brisk, especially in the secure rim and night latch branches. The japanners and tin plate workers have a more favourable inquiry this week, on account of the Colonial and South American markets. The home demand for coal vases is quite buoyant. In agricultural implements and ironwork rather more is being done throughout the district, and other descriptions of heavy hardware are in better demand. The dispute between the fine plate locksmiths and their employers on the question of wages is not yet terminated, and there is every reason to believe that the discontented workpeople will join the Co-operative Association of Fineplate Locksmiths, already established with much success in Wolverhampton.

At Willenhall, the lock trade is steadily improving, but the curry-comb makers have not full employment for their workpeople. The Bilston japanners and tin plate workers have a fair demand for goods adapted to this season of the year. At Wednesbury and Darlaston the engineering ironwork makers are doing an improved business, especially on account of the East India market. The Walsall saddlers' ironmongers have a much better home demand for bits, stirrups, and other malleable ware. At Westbromwich the ironfounders are doing more business in the kitchen ware department, and the mill and forge castings branch is reported better. Chilled rolls command a fair inquiry. At Tipton the chain, cable, and anchor makers are fairly employed on Admiralty contracts, but the general merchant's trade is scarcely so favourable. The nail-makers' "strike" continues without any prospect of immediate settlement. Large numbers of them, with their wives and families, have left the district for Kent, on a hop-picking tour. Over 1,000 of them, bent on this enterprise, left Stourbridge a few days ago by special train.

STATE OF THE TOWER BARRACKS.

THE *Lancet* Sanitary Commission on the state of the barracks of the Foot Guards has made public a condition of things with regard to the Tower of London not at all creditable to the War Office authorities. Soldiers, storekeepers, warders, policemen, and women and children, to the number of 1,062 persons, are confined within a space which is taken up principally by stores, workshops, ramparts, &c. Overcrowding presents one of the chief obstacles to the sanitary improvement of the fortress. The principal barrack is a modern structure, having a castellated appearance, internal comfort being sacrificed to external effect. The rooms are dark and prison-like, the windows are small, and there is no perfect ventilation. There are no ablution rooms, latrines, or urioals, under the barrack roof. The principal ablution room occupies the basement of one of the ancient towers, and is approached by a narrow staircase. It is dark, and the floor is perpetually wet. Over this is the cooking kitchen, and over this again is the library. It should be an imperative rule that kitchens should have nothing above them, so that a louvre opening may be made in the roof for ventilation: the heat, as here, is otherwise intolerable. The basement of another ancient tower is occupied by latrines, and is a most disgusting place. There is practically no ventilation, and the stench is overpowering. It is said that they have been condemned, and that new plans have been prepared; but no money has yet been voted for the purpose. Some of the married sergeants reside in the casemates, which have been constructed with a view of restoring the fortifications to their original state. These rooms, though large and lofty, are dark and ill-ventilated. More of these unhealthy and cell-like dwellings are about to be built, and it is to be hoped that the engineer officer entrusted with the designs will strive to make them a little more comfortable. The casemates are more adapted for ornament than for present use. They would not resist a single modern shell, and they are not likely to be tested. Small openings might be made in front for light and ventilation.

MEASURING WORK.

THE Islington Board of Guardians held a special meeting on Tuesday week, for the purpose of investigating the charge made against the contractors for the new workhouse of having used "improper" materials—*i.e.*, materials not in accordance with those specified in the contract—in the construction of the new building. In the course of the investigation, Mr. Burden, the architect, was examined, and in reply to a question he said that he depended upon the Clerk of the Works (Mr. Lewis) for the accuracy of the measurement on which he certified. He could not say it was the duty of the clerk of the works to make the measurements; he could only speak as to custom. It was customary for contractors on the one side, and the clerk of the works on the other, to send a statement as to the measurements to the architect, and if these tallied the architect gave a certificate.—A Guardian here observed that with such a system Mr. Burden would place himself in an awkward position should there be collusion between the clerk of works and the contractor.—The architect replied that either the clerk of works must do the work or he must do it himself. He was able to check the measurements by his plans.—A Guardian adverted to the fact that the measurement of the work took up the whole of the time of the clerk of works.—Mr. Lewis, in reply to a question, said that on all works where he had been engaged it was the custom for either the architect or his clerk to go over the work with the clerk of the works.—The architect said that the clerk of the works was supposed to work on the part of the architect and the persons who employed him. A part of his duty was to measure up the work for the architect, and this did not relieve the latter from responsibility.—Mr. Hillman said he had questioned a celebrated architect on the subject, and he had said that the duty of a clerk of the works was not to measure up work.—The discussion on this topic then dropped, and after some further conversation it was carried unanimously—"That the architect be requested to write an imperative letter to the contractors, requiring them to remove from the ground the whole of the defective materials within two days."—The Clerk of the Works suggested that for the future all materials brought on the ground should enter by one gateway, and that a gatekeeper should be appointed to inspect the loads.

SEPULCHRAL REMAINS IN SOUTHERN INDIA.

SIR WALTER ELLIOTT, in a paper read before the Ethnological and Geographical Section of the recent British Association meeting at Norwich, stated that some five-and-twenty or thirty years ago he examined a number of ancient cairns and tumuli on the Neilgherry Hills, which proved to be the burial-places of an extinct race The most common are simple circles, from 3ft. to 6ft. in diameter, formed by a few rude stones placed side by side, and sometimes enclosed within a larger circle or square of similar stones. A few that were opened contained only one or two earthen vessels, incinerated bones, and sometimes a few beads. These are occasionally deposited just without the circle, at a spot on the east side, where one stone projects beyond the curve. An extensive collection of these circles occurs at the Red Hills, near Madras, which had been the burial-place of an extinct race called Curumbars. None of the present inhabitants of the plain now deposit the remains of their dead in this fashion. A second kind of tomb is composed of a few large slabs of stone, generally four, placed upright, so as to form a square, and surmounted by a slab serving as a cover or lid. They are termed *pandis kulis*, and occur in all parts of the country, in great numbers on the banks of the River Noyel, in the province of Combatore. In some places, as at Chittore, there is a circular opening in the end stone, apparently intended for the introductory offerings to the dead, but which the natives consider to be an entrance or doorway, and say they were the habitations of a race of pigmies or troglodytes, whence the place goes by the name of the City of the Dwarfs. In a *pandukí* of this class were found, in three earthen vessels buried in the north-east corner, a necklace of gilded beads on clay or lac, a small string of hexagonal cornelian beads marked with white lines, four oblong beads and two smaller ones of crystal or quartz, a small armlet of thin gold plate, two gold bbuke or buttons, and some fragments of gold. Remains of iron implements, much oxidised, were also found. A third description of tomb is of frequent occurrence in the province of Malabar, called *Kodi Kals*, generally found on eminences or open slopes. They may be described as chambers excavated in the soil, with a descent of a few steps and covered with a convex slab, whence their name, from their resemblance to a *kodi* or umbrella. The chamber has a shelf on one side, and a conical cavity, in which a coarse earthenware vessel 4ft. or 5ft. high and 3ft. or 4ft. in diameter, like an amphora without handles, is deposited, its wide mouth covered by a stone lid. In one of these, on removing the cover, other smaller vessels were discovered, of various shapes, all containing burnt bones and a little fine shining powder or sand, which was also strewed about the bottom, on which also rested a saucer-shaped vase of fine glazed pottery, containing a string of crystal cup shaped beads. Other beads, and some oxidised pieces of iron, were found on the shelf. In the vicinity of these umbrella tombs are often seen other edifices in which the convex lid is supported on upright stones; but in none of these that have been examined have any remains been found indicatiog their purpose, whether monumental, sepulchral, or religious. They are called *Topi-Kals*, or "cap stones," and have much the appearance of gigantic mushrooms. The structures in the Neilgherries, like the umbrella and hat tombs of Malabar, generally occupy the tops of hills or gentle slopes surrounded by woods. The most common form of these cairns is that of a circular wall of uncemented rough stones, four or five feet high, three feet thick, and six to eight feet diameter inside, exactly like a draw well. Others are formed of tall, unhewn stones, set on end in a circle. Instances also occur, though more rarely, of conical earthen tumuli, and of circular cavities lined with stones, from which the earth slopes down on every side. Diversified as they are in form, the interior arrangement is nearly alike in all. On removing the upper soil, one or more long narrow slabs of unhewn stone are discovered lying horizontally, and, where there are several, parallel to each other, all invariably in the same direction—from north-west to south-west. On digging deeper the space between the slabs and between these and the wall is found to be filled with pottery, almost invariably broken, as if carelessly cast in. The vessels are for the most part empty, of a cylindrical form, with many rings, as if turned, and having rounded bottoms, but no handles. Most of them have lids, surmounted by rude figures of buffaloes, deer, elephants, tigers, bears, birds, snakes, or men. Sometimes the fancy of the potter has produced monstrous shapes of birds with two heads, or beasts ending in snakes. On clearing out this broken pottery and removing the stone slabs, one or more flatter vessels are found with or without covers, sometimes entire, sometimes crushed by the weight of the superincumbent stone, and containing a few burnt bones, and fine black or brown mould, together with gold or metal, jewels, beads, rings, &c. Others contain cups or vases of bronze or mixed metals, together with utensils which may have been used by the deceased, as spears, knives, sickles, razors, tweezers, all of iron, much oxidised. Traces of charcoal, resin, and other matters which may have been left among the ashes of the funeral pile also occur. The remainder of the paper contained a description of one or two cairns which Sir Walter Elliott had examined.

The once famous City Theatre, in Norton Folgate, known latterly as the City of London Theatre, will soon be numbered with the things that were, it having been purchased for railway purposes.

SOME INCONGRUITIES OF "REALISM" IN THE DRAMA.

THE new drama produced at the Surrey Theatre, on Saturday last, "Land Rats and Water Rats," by Watts Phillips, is decidedly Boucicaultish in character, a weak, improbable, and indistinct plot being made subservient to the prowess of the scene-painter and the property room. A real horse and cab are driven on to the stage, and a locomotive and train improvised by the scene-painter and (theatrical) machinist pass across. But while "realism" seems to be so fashionable with some authors, why do they not see that their scene-painters and machinists fulfil their portions of the work with fidelity? Old Blackfriars Bridge is the great *piece de resistance* in the new drama, but why is it a counterpart of Waterloo Bridge as regards the open balustrading? Within our memory Blackfriars Bridge was never flanked with anything but plain stone walls, except on such portions of the structure as were unable to sustain the weight of stone, where a wooden palisading was substituted. Again, the plot may reasonably be presumed to be laid at the present time, as the interior of the Langham Hotel is one of the scenes. Here we must blame the playwright. Old Blackfriars Bridge was closed before the Langham Hotel was completed, and before the old bridge was closed the London, Chatham, and Dover Railway bridge had been erected, and so effectually shut out the fine view of London as seen from the bridge formerly, and as depicted by the Surrey scene-painters. Again, the driving wheel (not wheels, for the train and locomotive only consist of a long painted partition with wheels underneath) of the locomotive must have made many a mechanic smile as he saw it on Saturday night, containing, as it did, only four spokes, formed by two bars crossing each other at right angles within a hoop, to say nothing of the absence of the driving crank. Surely if "realism" as to scenic effects and properties now constitutes the playwright's principal stock in trade, it is worth the bestowal of a little more attention. The representation of the Langham Hotel as contemporaneous with old Blackfriars Bridge and an uninterrupted view of London cityward from the latter, are matters that should not, for the sake of "realism," be unnoticed, and they are matters, moreover, at which the lover of the unsophisticated drama and the admirers of art will indulge a hearty laugh. The artist, in transferring the open balustrade of Waterloo Bridge to old Blackfriars Bridge, however, would seem to have a predilection for æsthetics rather than for "realism," and is, therefore, to be commended. Much as is talked about the prospects of the drama, it seems to us that the production of such pieces as "After Dark," "Land Rats and Water Rats," (depending as they do on "realism" in connection with things that should be of subsidiary interest) is anything but a favourable sign.

PUBLIC WORKS IN PARIS.

THERE are manifestly only two methods of executing any project or undertaking. One is to do it yourself, and the other to get somebody to do it for you. Under the latter method may be included every possible phase and branch of contracting, which is the favourite principle of carrying out work in this country. It is not to be understood that works of construction, both architectural and engineering, have not been executed by private parties in some instances; but in the main the preference is given, and justly too, to the contracting system. Owing to the advent of certain circumstances it has not unfrequently occurred that a railway company has relieved its contractor from his engagements when it became obvious that he was unable to duly fulfil them. A case in point happened in India, upon one of the great arterial lines, where, after the contractor had done a certain portion of the work, he being unable to complete the whole, the company took the contract off his hands, and finished the line not only in a most efficient manner but with great advantage upon the side of economy—a fact reflecting the highest credit upon its engineers and managers. The principle of contracting, although in the abstract implying merely the substitution of one party for another, yet comprises an almost infinite number and variety of ramifications, depending upon the obligations entered into under the contract.

Contemporaneously with the remodelling of our own metropolis, that of Paris is proceeding *pari passu*, and it is impossible to predict which will benefit most by its partial transformation. From various causes one uniform system of obtaining the execution of the magnificent works at present in different stages of progress in the French capital has not been adhered to. The magnitude, the uncertainty, and other features inseparably connected with their construction has prevented this desirable result. This is the less surprising when it is borne in mind that the transformation of Paris has been commenced and steadily and persistently carried out for the last fourteen years. Strictly speaking, there is no system on the continent answering exactly to our contracting. Both the methods of "adjudication" and "concession" have many points in common with it, but yet do not realise the precise signification we attach to it. The works connected with the improvements of Paris have been accomplished partly by "direct execution," a phrase self-explanatory, and partly by "concession." A glance at what has been effected in the French metropolis will suffice to indicate that the municipal authorities do not intend to be behind ourselves in providing for the health and comfort of the inhabitants of their chief city. With a few exceptions our main thoroughfares are by no means very ample in their dimensions, but those of Paris are, or we should say were, still more contracted and limited in their accommodation for traffic. Naturally, therefore, the attention and energies of the legislative authorities were in the first instance directed to the widening, straightening, and general amelioration of their public routes, and in pursuance thereof three principal plans were laid down. Of these the first was commenced seventeen years ago, and is now completely finished. It embraced a total course of six miles, and cost eleven millions sterling, but the benefits it conferred more than compensated for the expenditure it entailed. Air and light were by its means distributed over a district in which the narrow and tortuous alleys and lanes forbade the slightest circulation of the vitiated atmosphere, and swift demolition befell the old obscure and dilapidated localities and purlieus in the vicinity of the Tuileries, the Louvre, the Palais Royal, the Hotel de Ville, and la Cité. The extent of the second projected system of streets, commenced just ten years ago, is thirteen miles, and consists chiefly of routes rendered necessary by the enormous development that modern times, together with the introduction of railways, have produced upon all metropolitan cities. It constitutes the principal means of intercommunication between the railway, telegraph stations, and most of the foci of official importance, and affords a convincing proof of the uncertainty attending the cost of all works of a corresponding magnitude. The original estimate was nearly three millions and a quarter, and it is calculated that when the system is completed the expenditure will reach nearly seven millions. No doubt additional works and extensions have been made which were not contemplated in the original estimate, but they could not have been sufficiently extensive to cause an increase exceeding by 120 per cent. the total sum first allowed for. The third system, both in cost and extent, is about equal to the first, and, although decidedly a great improvement to the city, is nevertheless not characterised by that amount of utility unquestionably belonging to the two former. It is rather a work of expediency than one of absolute necessity, although some portions of it may be said to have been rendered imperative by the extensions already accomplished in the other two. No such anomalies as *cul-de-sacs* could be permitted in the transformation of an imperial metropolis.

The experience gained by the carrying out of the Parisian improvements, in which, as we have already stated, the principles of direct execution and that of concession were both employed, resulted in the recognition of the latter as the preferable method economically considered. One great advantage of this plan was found to consist in the personal interest it gave to those responsible for the accomplishment of the task, and the superior activity, energy, zeal, and ability exhibited in the pushing on and rapid completion of the works. The results would have been probably still more satisfactory had it been possible to employ the method of adjudication, which has been most successfully adopted in the construction of the railways. The peculiar manner in which the financial arrangements were effected precluded the practicability of employing the method of adjudication. Where the "concession" plan is employed the means of arriving at its cost is thus determined. So soon as a certain work—suppose the opening up of a new route—is determined upon, a preliminary estimate of the expense is made by the municipal officers, who base their calculations upon the results of similar works already accomplished. This valuation is submitted to a committee appointed especially to examine into such matters, and the fiat of the members ultimately fixes the price of the concession. No concession is ever granted without this check upon the estimate being performed, and the lodgment of a proportionate amount of caution money, as a guarantee for the fidelity of his intentions, is the only condition imposed upon the contractor. Referring to a report lately published, relative to what may be termed the inner working of the French systems of contracting, it is manifest that they are free from the great majority of the blemishes which attend our own, which, in fact, disgrace many of the parties connected with the execution of large public works, and cast a shade of distrust and suspicion upon those who ought in no manner whatever to be concerned with the financial part of the undertaking. When £10,000 is added to an estimate to ensure the fulfilment of the contract, it is time for our municipal authorities to seriously consider whether the principle of direct execution would not be preferable to the system of contracting.

WALTON SEWERAGE, LIVERPOOL.

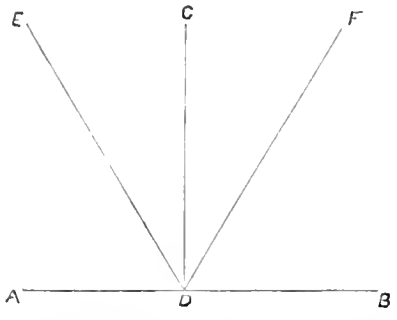
IT appears that the Walton Board do not intend adopting Mr. Rawlinson's advice to join the township of West Derby in a joint outlet for wasting the sewage into the River Mersey. They have instructed their engineers, Messrs. Reade and Goodison, to modify their utilisation scheme so as to adapt it to the disposal of the sewage of Walton alone. The following resolution was adopted unanimously at the last meeting of the Board:—That as there does not appear any probability of an agreement being come to between the West Derby Board and that of this township for a joint outlet sewer for the disposal of the sewage of both townships by utilisation, the engineers be instructed to modify the plans so far as to make the outlet sewers applicable for the township of Walton only, due provision being made in such altered plans for prospective increase of population.

The congress of German architects, which has been sitting at Hamburg, was closed on Friday last.

THE THEORY OF SHADOWS.*

EVERY one who regards himself as a finished draughtsman ought to be thoroughly *au fait* at the various descriptions of perspective, including lineal, parallel, geometric, and aërial, and at any rate acquainted with the science of shadow drawing. We have known many first-rate draughtsmen who knew absolutely nothing about sciography and the correct projection of shadows. They were literally unaware that shadows could be defined with the same degree of accuracy and fidelity with which the contours of substance can be delineated. In addition to ignorance upon the point it was not considered as a matter of much importance. The eye was assumed to be quite a sufficient guide, and provided the outlines of the objects were correctly ascertained, the shadows might be simply sketched in without any effort to define their proper limits with that mathematical accuracy of which they are capable. Yet there is very little doubt but that the just delineation of shadows, not only of their outline, but also of their relative tone and depth, is a subject of the greatest importance in either architectural or artistic productions. It is in the former of these that the deficiency of an unpractised eye and an ignorance of theory would be most apparent, since the character of the drawing being of a rectilineal kind would betray an error sooner than the latter. The theory of shadows is usually treated of in text books relating to descriptive geometry, and it must be confessed that the subject is not a very attractive one, except to those possessing a strong taste for geometrical analysis.

Mr. Puckett, in the work to which we refer, has treated the subject of the projection of shadows in a series of lectures illustrated by accompanying diagrams. Perhaps this gentleman would allow us to point out one fact to him, of which, by the arrangement he has adopted in his volume, he does not appear cognisant. However admirable a series of lectures may be when delivered orally, it by no means follows that they will read equally well. It is the same with all speaking, and in nothing more manifest than in pulpit preaching. A sermon that is perfect when well delivered will often be found to read but very indifferently, and one that can be read with pleasure would be completely spoilt by public declamation. In compiling a book of a number of lectures there is a dissimilarity and a want of sequence which become very unsatisfactory. This is not noticed in the lecture and class room, where the one lecture succeeds the other in its proper time, and the whole system of education is based upon this recognised foundation. But to gather together the information that has been spread over a certain period, and publish it in exactly the same unconnected form in which it first appeared, is a complete mistake in the art of "book-making." It is easy to perceive that the author is master of his subject, and thoroughly understands the principles of tuition. He commences by the case of a simple block, and proceeds to the more intricate and complicated examples in subsequent lectures. Every step in the working out of a diagram is clearly demonstrated, and all the necessary points, lines, and projections truly and correctly defined. This care is the more necessary in the solution of all problems depending upon geometrical reasoning for their accurate determination. It must be borne in mind that the successive steps are not only dependent upon one another, but combine to make up the whole figure. They constitute so many links, whereof if one be broken the whole of the problem become obscure and unintelligible. If the student is unable to determine the position of one of the lines, or ascertain the necessary projection, he can go no further with the problem, as it is very rarely that he can supply the missing link in the process. The case is otherwise with analytical reasoning or calculation, where if a step in the operation be omitted the pupil can generally supply it if it be not of a very complicated nature. The subject of sciography includes three descriptions of the projection of shadows—one where the cause is natural light, the other where the shadows are generated by artificial light, and the third where they are due to the medium of reflection. In the two first the theory is nearly identical, and there is only one position for the source of light, which is assumed to be in front of the observers. A few examples are all that is required to elucidate the projection of shadows by artificial light. Reflected light, and the projections of the shadows due to its agency, are founded upon the well-known physical law that the angle of incidence is equal to the angle of reflexion, and that when one is given or is a known quantity, the other is also known. As this is a very important law, we will explain it a little in detail. Let A B be the surface of a mirror or of any reflecting substance, such as a sheet of water or quicksilver, and



let C D be a perpendicular to it at the point D. If E D represent the incidental ray falling upon the surface at the point D, then E D C will be the angle of incidence, and E D A its complement. Similarly F D C will be the angle of reflexion, and F D B its complement. Bearing in mind that C D A is a right angle and calling the angle of incidence θ, and that of reflection ϕ, we shall always have the following equalities, $\theta = \phi$: angle E D A = angle F B D = $(90° - \theta) = (90° - \phi)$. The plates in this little volume are distinctly and clearly lithographed, and the lettering, a most important point, has been carefully attended to. Anyone who uses the treatise must do so with the full intention of becoming thoroughly acquainted with the contents, as there is no other way open to him but to take his drawing board and squares and work out to a good large scale the various diagrams explanatory of the problems. It is essentially a practical book, and imparts a knowledge of sciography by the only methods by which it can be adequately acquired.

* "Sciography or Radial Projection of Shadows." By R. CAMPBELL PUCKETT, Ph. D., Head Master of the Bath School of Art. London: Chapman and Hall, 193, Piccadilly. 1868.

BUILDING IN SAUCHIEHALL STREET, GLASGOW.

OWING to the rapid and steady westward extension of Glasgow, Sauchiehall-street has, in the memory of those still comparatively young, passed from being a quiet country road to be a busy thoroughfare, so that where but a few years ago the suburban villa was seen nestling snugly among shrubbery and trees, with green lawn and flower plots interspersed, are now to be seen long continuous ranges of tall buildings, the upper stories of which are divided off into commodious dwelling houses, after the Scotch method, and the street floor occupied as first-class shops, containing all conceivable commodities requisite for the comforts of those residing in the still rapidly extending west end. Hitherto, however, these remarks were true only of the south side of Sauchiehall-street, the north side, west of the Corporation Gallery Buildings, still remaining in the same condition in which it was forty or fifty years ago. The circumstance of one side of this street being occupied by detached villas and gardens has rendered it a favourite and pleasant thoroughfare; but it has been evident for years that the north side of the street was doomed to a change also; there being an increasing demand for shops in this locality, there were not wanting those who saw the profit that would accrue from erecting buildings to supply this demand. Fortunately for the amenity of the street, the building an illustration of which is given in our present number has been restricted by the proprietor to three stories in height, an example which it is to be hoped will be followed in the case of such buildings as may afterwards be erected in the same line of street.

This building has been erected with the view of being occupied as shops and warehouses, the ground having become too valuable for dwellings. The frontage to Sauchiehall street measures about 126ft. and to Scott-street about 60ft. The building was described pretty fully by "our Glasgow correspondent," on the 24th of April last (No. 694). Messrs. A. and G. Thompson are the architects.

A NEW "ROAD STEAMER."

GREAT efforts have been made within the last few years to apply steam power to the draught of loads on common roads, but two difficulties have hitherto hindered these efforts. The first difficulty was the jar caused to the machinery by travelling over a rough road, if the locomotive was lightly built; and the second obstacle was that if the locomotive was made heavy and large, in order to obviate this first difficulty, it was only done at the expense of the roads which would suffer greatly. Mr. Thomson, a civil engineer of Edinburgh, has, however, overcome these difficulties in a manner which appears to be highly satisfactory, although by very simple means—viz., by fixing stout india-rubber tires to the engine wheels. The various trials of these engines appear to have demonstrated the success of Mr. Thomson's expedient. One engine, weighing 8 tons, was recently tried in Edinburgh. It drew a train of four waggons, each weighing 2 tons 15 cwt., and each loaded with 5½ tons of coals, making, with the engine, a weight of 40 tons, from a colliery twelve miles from Edinburgh, to the latter city, although built to draw only 15 tons. The train (90ft. long without engine) travelled with perfect ease along a road having inclines of 1 in 16. Reaching Edinburgh, it deftly threaded its course amid the streams of ordinary traffic, over beds of broken stones, dodging through barriers for the protection of the road-menders, turning sharp corners, and descending steep streets, describing serpent-like sinuosities as the exigencies of the steering demanded. The whole trial was very complete as a demonstration of the tractive power of the engine, and of the perfect control over it possessed by its driver. Professor Archer, in a paper read before the British Association, compares the india-rubber tires to the cushioned feet of the elephant and camel, than which it is probable that the tires will be hardly more destructible.

DRAINAGE OF THE FENS.

AT the recent meeting of the British Association at Norwich, Mr. G. W. Harding read a paper on this subject. He confined himself to the Bedford level, comprising 300,000 acres of land in the counties of Cambridge, Norfolk, Suffolk, and Huntingdon. Having remarked upon the scanty materials left by history as to the period at which attempts were first made to reclaim this important tract of country from the water, and glanced at a tradition that this attempt was to be attributed to John of Gaunt, at the latter end of the fourteenth century, he passed on through the reigns of several sovereigns to that of Elizabeth, in which a commission of sewers was issued, with the object of draining what was known as the North Level. Nothing, however, was done for twenty-three years, when, through the exertions of Sir William Cecil (afterwards Lord Burghley), the first statute was passed proposing a general plan for draining the whole great level. A multiplicity of commissions were issued during the reign of James I., and so many disputes and difficulties arose that the king himself eventually became the undertaker of this great work, for which he was to receive 120,000 acres. An engineer and workmen were obtained from Holland, but the work did not proceed satisfactorily, and was eventually given up. Nothing more was attempted until the fifth year of the reign of Charles I., when a tax of 6s. per acre on the

land in question was imposed for carrying out the work, but no part of the tax was paid, nor was anything done. Mr. Harding thus advanced by easy stages to the present times.

THE DRAINAGE OF PARIS.

DURING the last few days one of the bridges, the Pont de l'Alma, near the Champ de Mars, has been crowded with people overlooking an exciting mechanical operation—the laying down at the bottom of the Seine of two enormous water pipes, to complete the system of Parisian sewers, which are themselves almost a city, having main avenues, thoroughfares, passages, and cross-roads. In consequence of the Seine running through Paris, and dividing the town into two distinct portions, the drainage on each bank has been hitherto independent, one branch being carried off to Asnières, and the other coming out at the Pont de l'Alma. But it was deemed necessary to avoid infecting the water at this spot, and so the engineers decided upon joining the two branches together. They began by constructing a kind of underground canal from the Pont de l'Alma to the right bank main sewer. This was dug at the depth of 105ft., and took three years to complete, without any other display of works on the surface than a few wells and engines here and there. All that then remained to be done was to join the two branches by means of an enormous iron siphon, for ensuring the regular circulation of the sewage from one side of the river to the other. It consists of two tubes, one metre wide, two centimetres thick, and 124 metres long, made of two sheets of iron one over the other. A bed of concrete has been made across the river: it is to receive these tubes, which are now being laid—a gigantic operation, wherein no fewer than 150 workmen are employed. So great are the difficulties encountered in laying down the tubes, from the strength of the current and other causes, that several attempts have been unsuccessful as yet, and the mode of working has been changed in consequence. Divers go down continually to watch the proceedings. A day or two ago a jerk in the machinery threw over one of the chief contractors, M. Gonin, who, however, escaped unhurt. No similar work has ever been undertaken before, so that the excitement caused by this one is not to be wondered at. But it stops all navigation on the Seine at present, and the river is encumbered with boats awaiting the accomplishment of the work. This is expected to be effected in a very few days.—*Paris letter.*

THE CONSUMPTION OF SMOKE.

THE first inquiry by a Government inspector, under the 49th section of the Sanitary Act, 1866, was held by Mr. Rawlinson, at Hanley, on Tuesday and Wednesday of last week. Under this section, where a local government fails to enforce the act on a complaint of a number of the inhabitants, the Home Secretary is empowered to call upon the defaulters to do their duty, and, if necessary, appoint an inspector to put the act in force. When the Sanitary Act was passed, the town council of Hanley adopted its other provisions, but neglected to enforce the clauses requiring the consumption of smoke created by manufacturing processes. The nuisance arising from this cause in Hanley has been very great, and some three months back about 200 inhabitants of the town memorialised the Secretary of State to send down an inspector to enforce the smoke clauses. This being the first application under the 49th clause the Home Secretary instituted a preliminary inquiry, which was held as above stated. Evidence was given of the neglect of the town council to put the smoke clauses in force until after the memorial had been got up, of the serious nature of the nuisance arising from the large quantity of smoke emitted from the chimneys of the town, and, on the other hand, to show that of late the nuisance had been to some extent abated. Mr. Rawlinson intimated that as the town council had at last taken steps to enforce the act they would be allowed to proceed; but if they relaxed in their duty the Home Secretary would consider it necessary to take the matter out of their hands. He also hinted as extremely probable that if local authorities neglected to put the act in force the whole of the manufacturing districts would be placed under Government supervision in regard to the smoke clauses.

ARCHÆOLOGY.

A VERY fine sepulchral urn was discovered last week in a barrow on the top of Tredinny hill, near the Land's End. It was found to a Kist-vaen, formed by eight stones in layers of four. It was resting on a granite rock and was covered by a flat stone. The measurement is about 8in. by 13in. The urn is perfect except the bottom. It has four handles and is ornamented by a rude chevron pattern. It was filled with human bones. A few flints were found on the removal of the earth, and a considerable quantity of ashes lay around a large rock in the centre of the mound, on which it is believed the body was burnt.

An interesting archæological discovery has been made in a railway cutting at Pont de Pierre, not far from Châlons-sur-Saone. At 3ft. below the surface of the ground, a group of thirteen skeletons was found in a narrow space, and wonderfully preserved. They seem to be the bones of full grown men who had died in battle. The skeleton of a woman has been discovered among the others. Between the jaws of one of the dead was found an obolus, which the friend of the defunct had perhaps slipped in to enable the departed to pay his fare to Charon. A coin very much defaced, but still seen to bear the effigy of the Emperor Gordian was also picked up among these remains, which leads to the conclusion that 1,700 years have elapsed since they were interred.

At a meeting of the Newcastle Antiquarian Society on Wednesday week, a letter was read from Mr. "W. J. Rose," London, offering to the society a collection of prehistoric flint implements which he had collected in Denmark. He asked £2,000 for the collection. The secretary replied, stating that they were not in a position for making such a purchase. Mr. Rose answered that he would abate something of the price. The secretary replied that they had not funds for the purpose. The secretary said he questioned the value and genuineness of the implements offered.

At a special council of the British Archæological Association on Thursday week the following were appointed a committee for insuring the illustration and preservation of the Fairford windows:—Earl Bathurst (president of the association), the vice presidents, officers, and council of the association; the Rev. T. D. Rice, M.A., vicar of Fairford; the Ven. T. Thorpe, Archdeacon of Bristol; the Rev. Canon Powell, vicar of Cirencester; the Rev. Canon Howman, Mr. Tom Taylor, Mr. B. B. Woodward, F.S.A., librarian to the Queen at Windsor; Mr. T. W. Reid, Print Department, British Museum; and Mr. J. D. T. Niblett, M.A., F.S.A., all of whom have consented to act. It was resolved to invite other persons distinguished in art to join the committee, including the presidents of the Royal Academy, Society of Antiquaries, Institute of Architects, and the Archæological Institute. A "Fairford window account" has been opened at the National Bank, Charing Cross, and some subscriptions are already paid. The hon. secretaries of the association, Messrs E. Levien, M.A., F.S.A., and G. E. Roberts, F.S.A., act as honorary secretaries to the committee.

A correspondent to the *Cork Examiner*, writing from Dingle, says:—The Earl of Dunraven and Dr. Stokes, of Dublin, have been here on an antiquarian excursion. Yesterday they visited the crumbling ruins of Minard Castle, which was blown up by Cromwell's soldiers. In the course of his visit Lord Dunraven was afforded a specimen of the way the precious antiquities of the country are being swept away. This is his lordship's third visit, and, acquainted as he was with the district, he naturally looked for Kilmurry church, or rather oratory, above the castle. To his astonishment it had disappeared. A farmer explained to his lordship that about ten years since a proprietor had thrown it down to employ the materials in building his own house.

WATER SUPPLY AND SANITARY MATTERS.

THE sewage experiments lately tried at Clichy on the Seine, and favourably reported on by a jury appointed to taste the fruits, vegetables, &c., produced, are about to be pursued on a much larger scale on the plain of Gennevilliers.

New drainage and water works have just been completed at Bedford. The water reservoir is a subterranean brick built tank, capable of holding 400,000 gallons.

Building Intelligence.

CHURCHES AND CHAPELS.

Kingsland Church, Herefordshire, was reopened yesterday week, after restoration. The church, which is dedicated to St. Michael, was built in the reign of Edward I., and is a very interesting specimen of Early Fourteenth Century work. The restoration embraces the removal of the old pews, and the erection in their place of new oak benches, the chancel being fitted with stalls of the same material. The nave roof, previously ceiled, has been opened out and restored, the chancel roof painted decoratively, and the windows in this portion of the church filled with stained glass, which has been made to harmonise with some ancient figments that remain. The altar has a rich frontal, and is duly furnished with cross and candlesticks. The stonework in the interior of the building has been repointed, as also have the exterior walls, the tower excepted. Mr. Smith, of Tenbury, is the contractor by whom the work has been carried out. The cost of the restoration is estimated at about £1,400. Mr. G. F. Bodley, of Harley-street, London, was the architect.

Three of the oldest churches in the county of Lincoln are now undergoing a thorough restoration, viz., Barrow-on-Humber, Habrough, and Horkstow. Barrow, the ancient church of St. Michael and All Angels, is a fine specimen of Perpendicular Gothic, and contains many mural monuments. The architects employed are Messrs. Kirk and Parry, of Sleaford, and the builder, Mr. A. Stump, of Barton. The cost of the entire work will be about £700. The same architects and builders are also employed at Horkstow, where the old church of St. Maurice, a fine specimen of the mixed style of Saxon and Norman architecture, stands.

The new church of St. Paul's, St. Leonards-on-Sea, was opened on Thursday, the 27th ult., and has been built at the sole expense of the late William Gilliat, Esq., of East Hoathly, from the designs of Mr. John Newton, architect, Salisbury-street, Adelphi. It consists on plan of nave and two side aisles. East of the nave is the chancel and a horseshoe-shaped apse. On the north of the chancel is the tower, and on the south a chancel aisle. There is a north and south porch. The church is built externally of rough blue local stone, with Bath stone dressings, and is lined internally with red brick and tile, the masons' work being executed in Caen stone. The chancel and apse are groined throughout, and the ashlar is constructed of red brick and incised stone bands alternately, the ribs being carried by wide antique shafts. The tile pavements in the apse and chancel are most elaborate, of marble and Minton's tiles; the altar space, containing incised marble slabs, displays the emblems of the sufferings of our Lord. Beneath this, and east of the altar rail, are five very beautiful medallions in incised marble, illustrating the martyrdom of St. Paul, St. Stephen, St. James, St. Peter, and the Slaying of the Innocents. The spire is as yet not completed, but will be shortly finished. The church has already cost about £12,000. The contractors are Messrs. Jackson and Shaw, of Earl-street, Westminster. Messrs. Farmer and Brindley have executed the carving, and Mr. Robinson, of Holborn, the stalls. The building has been carried out under the immediate supervision of Mr. J. Walters, the clerk of works.

The following city churches are at present closed for repairs or cleansing purposes:—St. Margaret's, Lothbury; St. Mary, Woolnoth, Lombard-street; St. Michael Bassishaw, Basinghall-street; St. Michael, Wood-street; St. Matthew, Friday-street; St. Peter-le-Poer, Old Broad-street; St. Giles's, Cripplegate; St. Swithin, Cannon-street; St. Mildred, Poultry; St. Michael, Cornhill; and St. Ethelburga, Bishopsgate.

Whitfield's Tabernacle, Tabernacle-walk, City-road, is to be re-erected. The foundation stone of the new structure will be laid this (Friday) afternoon by Mr. J. Remington Mills, M.P.

On Thursday week, a new church, dedicated to St. Peter, was consecrated at Sidford, Devon. The edifice is in the Early English style, and consists of a nave, two side aisles, a chancel, with its aisle, and a vestry. Red brick is the material used, with dressings of Bath stone. Messrs. Gosling and Selway, of Ottery St. Mary, were the builders.

The parish church of Wembdon, near Bridgwater, destroyed by fire last spring, is to be rebuilt from plans prepared by Mr. J. M. Hay, architect, Bath.

BUILDINGS.

New Wesleyan Schools have been opened at Bolton this week. They are L-shaped, and contain an area of 2,850ft. The style is Gothic, the exterior being of brick, with stone dressings. The cost is £2,000. Messrs. Cunliffe and Freeman, of Bolton, were the architects, and Mr. John Merrick, of the same place, the contractor.

A new mechanics' institute was inaugurated on Tuesday evening, at Crook, near Durham. The building is of stone, with ornamental window dressings, and contains a lecture hall, 50ft. by 30ft. The total cost was about £1,200. Mr. J. D. Thompson, of Bishop Auckland, was the architect, and Mr. John Thompson, of the same place, the principal contractor.

The schools in connection with the Baptist Chapel at New Swindon are now being greatly enlarged and altered, at a cost of £1,400, from plans prepared by Mr. T. S. Lansdown, Mr. Thomas Barrett being the contractor.

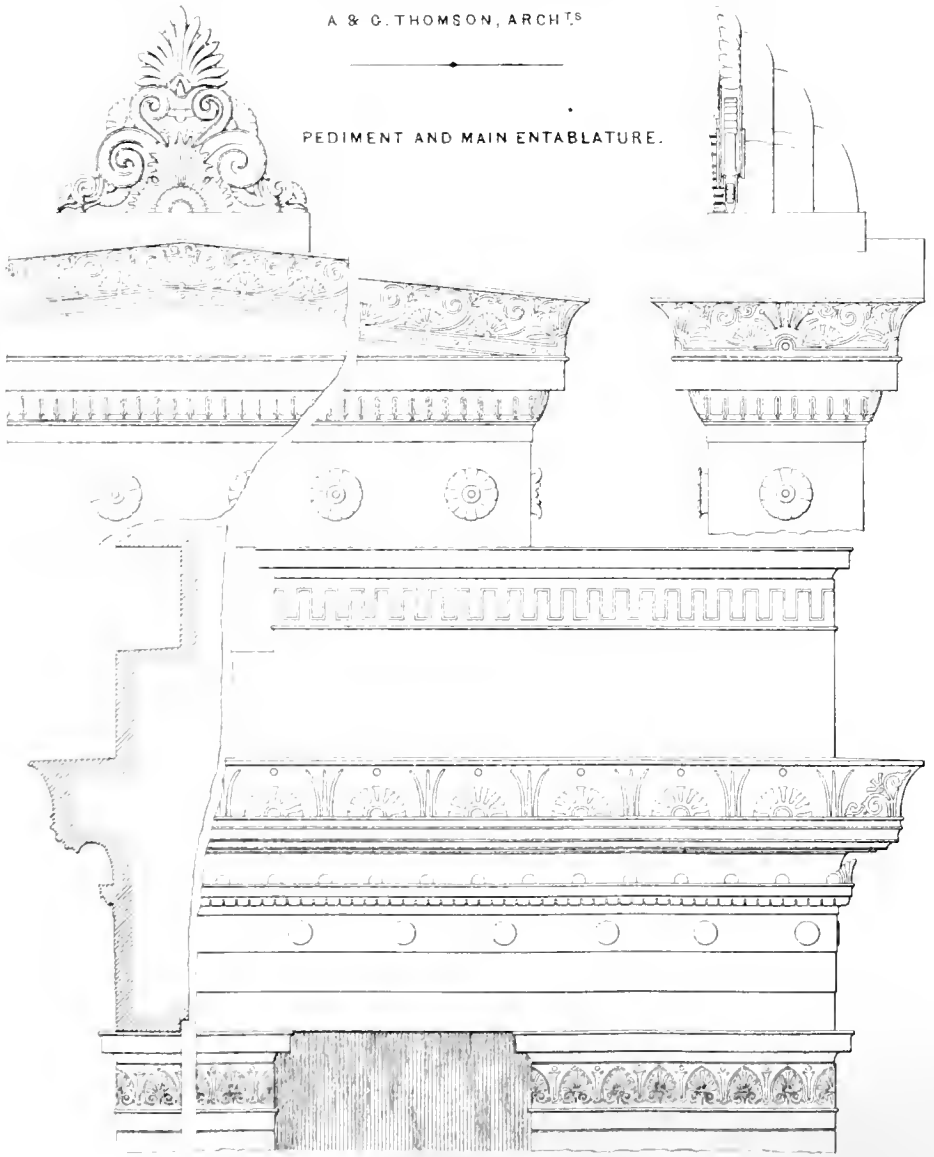
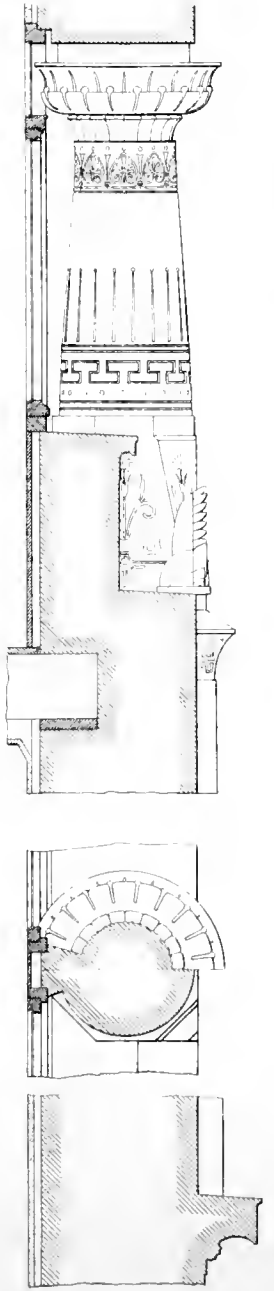
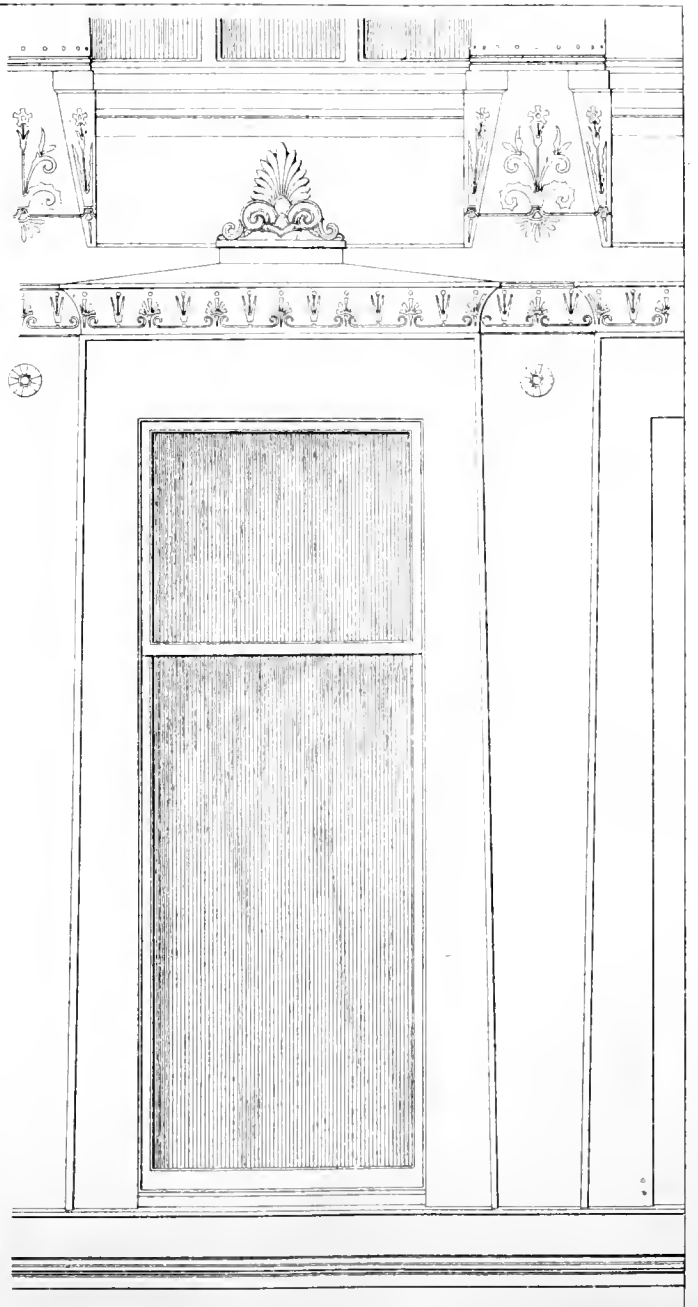
PEDIMENT AND MAIN ENTABLATURE.







WINDOWS OF UPPER FLOORS.

12 9 6 3 0 1 2 3 4 5 6 7 FEET

The members of the Granby Lodge of Freemasons, No. 24, Durham, intend to erect a new Masonic hall in Old Elvet, Durham, and the plans of the building were passed by the Board of Health on Wednesday, the 2nd inst. The building will be erected from designs by Mr. T. C. Ebdy, architect, Durham.

A new small-pox hospital is about to be erected at Calcutta. There are to be four wards, 92ft. by 42ft., capable of receiving from 30 to 40 patients, with 1,738 cubic and 90 superficial feet for each person. Four small wards for infectious cases, 10ft. by 8ft. each, will be attached. The entire cost, which is to be borne by Government, will be 35,000 rupees.

A new pauper hospital is to be erected at Rotherhithe. Accommodation will be provided for 500 patients, and the cost will be £30,000.

The Town Council of Blackburn have just decided upon the erection of a new fish market, at a cost of £3,950.

The Bolton Gas Company have formally opened their new offices. The structure has been erected from designs of George Woodhouse, Esq., and under the superintendence of Mr. John Handford, clerk of the works. The style of architecture adopted is Venetian Gothic. The block covers an area of 518 superficial yards, and has a frontage on three sides. The principal entrance is in Hotel-street, and has a richly-moulded archway supported by four red granite columns, with carved caps, with cusped tympanum. Over this doorway rises a tower, square on plan, and slated roof spirelet, the roof having small gablet dormers on each of the four sides, with finials, and the summit of the roof being surmounted with a wrought-iron cresting and flagstaff. The interior of the building is elaborately fitted up. The floor of the vestibule or principal entrance is laid with encaustic tiles. From the vestibule a stone staircase rises which leads to the show room, manager's room, board room, and the upper story of the building, the minor offices and store rooms being approached by a back staircase of stone. The contractor for the shell of the building was Mr. John Thompson, of Manchester; for the internal oak fittings, Mr. James Morris, of Deansgate, Bolton; and the pine fittings, Messrs. Day and Raby, of Bolton. The painting and decorating are by Messrs. Lomas, Manchester and Bolton.

TO CORRESPONDENTS.

NOTICE.—Cases for binding the BUILDING NEWS, Vol. XIV., are now ready, price 2s. each.

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

RECEIVED.—J. C. T.—P. and S.—R. and G.—G. C. H.—J. P. S.—Drake B others and Co.—C. R. R R.—E. I. B.—C. T. P.—I. W.—I. H.—I. O.—H. W. B.—A. and G. T.—I. H. T.—S. G. and Sons.—W. S.—"A Young Architect."—C. B. A.

ERRATUM.—In our report of the result of the Abergavenny Townhall and Markets it was stated that the second prize of £20 had been awarded to Mr. G. C. Haddon, of *Hereford*, instead of Hereford, in which town that gentleman practises.

TOLERATION.—We pay no attention to anonymous letters. Your "master" is evidently a born flatterer.

Correspondence.

BUILDING SOCIETIES.

To the Editor of the BUILDING NEWS.

SIR,—I foresee that you will do good service by kindly allowing the ventilation of this subject in your columns, and I ask for space for one or two remarks with reference to the courteous letters, both signed "S. S," from your correspondents in Masbro' and London. As it will simplify matters in this case the "last shall be first." "S. S," assumes (*a*) that a house worth £36 per annum can ordinarily be bought for £300, and (*b*) that the whole of the purchase money can be borrowed from a building society. These two assumptions are, I think, so erroneous as to be fatal to his argument. As a rule, houses are not purchased to pay the buyer 12 per cent. or 9 per cent. nett, after providing for all the annual charges and risks, and it would not be safe to generalise from exceptional instances.

I think I shall be borne out in saying, first, that a house *worth* £36 per annum, and worth buying at all, would not ordinarily be bought for less than £400; and secondly, that few building societies lend more than three-quarters of the purchase money.

Now let us re-consider his illustration, in the first case assuming that I purchase the house by borrowing £300 from a building society and paying down £100; and in the second case, that I continue to pay £36 per annum as rent and invest my annual surplus at interest.

First case.

Annual repayments on loan of £300	£42	0	0
Loss of interest on £100 paid down	5	0	0
Ground rent, insurance, repairs, and contingencies...	10	0	0
Annual outgoings	£57	0	0
Deduct rent	36	0	0
Annual excess	£21	0	0

Second case.

£21 per annum invested for ten years	£298	0	0
£100 capital	162	0	0
Money in hand at expiration of ten years, having all that time paid rent.	£460	0	0

So that I am in a position to buy a similar house, which shall be just entering on its lease, instead of having run out ten years of it, and shall, besides, have £60 to the good. Your Masbro' correspondent, in admitting that I can rent a house on easier terms than I can buy one through a building society, yet tells me that at the end of so many years I should, in one case, have a house of my own, and in the other "be where I began" What, then, has become of the annual surplus due to the comparative "easiness" of the terms? I have shown above that I should be very far from 'where I began;" I should have *more* than a set-off against the house in hard cash, thus justifying my former assertion, that, as matters now stand, it is really wiser to continue to pay rent to a landlord than to buy a house through the *aid* of a building society.—I am, &c.,

E. INGRESS BELL.

30, Regent-street, Waterloo-place, S.W.

SIR,—Your correspondent, "E. Ingress Bell," notwithstanding his experience, seems to have very confused notions of the nature and character of building societies. He must have been most unfortunate while acting for and on behalf of his clients in transacting business with building societies so badly constituted or improvidently employed as for it to be *wiser* to continue to pay rent to a landlord, instead of seeking the aid of a properly constituted building society to purchase the property so rented.

One fact is worth many figures, as figures, if not correctly placed, invariably delude and deceive; I may, therefore, state, in opposition to the experience of your correspondent, that I know several working men now in the possession and enjoyment of their own freeholds, who have purchased them through the aid of a building society, whose subscriptions and interest to such society for fourteen years have amounted to less than they must have paid to the landlord for rent in the same time.

It is readily admitted that all property cannot be purchased so as to work out thus satisfactorily, but it is manifestly unfair to charge upon building societies the inconveniences arising from a reckless and improvident purchase. And that must be a most reckless purchase which would lead to the conclusion asserted by your correspondent, unless, indeed, the purchaser had sought aid from a building society established by money lenders for their own special benefit, without regard to the interests of those for whom such societies were originally established.

Almost every good thing has been counterfeited, and it is just possible that your correspondent's experience may have been confined to the counterfeits; if so, every honest man ought to join with him in denouncing such.

Every provident man who intends to become a borrower from a building society should take care to join a *mutual* one, that is, one so constituted that all the profits are mutually to be divided among the members. This was the original intention of their establishment, and it should ever be kept in view. Then provident men may with propriety be asked, "Why pay rent?" "Why not pay a little more for a few years, and the house becomes your own property?"—I am, &c., A COUNTRYMAN.

Thetford, Norfolk.

TEMPERANCE HALLS.

SIR,—Charles Dickens, in describing the premises which "The Brick-lane Branch of the Grand Junction Ebenezer Temperance Society" occupied in the neighbourhood of Spitalfields, describes the characteristics of a vast number of existing teetotal meeting places, which are, by courtesy, denominated Temperance "Halls." Those not situate in a loft or approached by an almost perpendicular stable ladder, will, for the most part, be found to be low ceiled, irregular shaped apartments, devoid of any efficient means of ventilation, lighting, or egress. In the majority of cases, also, the "hall" will consist of some old stable or dilapidated workshop, and, if neither of these, it will be improvised by opening the folding doors between two rooms in a small house. From these remarks the reader will correctly infer that the temperance "hall" is indigenous to the poorer streets of the metropolis. It eschews main thoroughfares, however, more from necessity than from inclination. Now I do not make these remarks with a view to disparage the temperance movement; on the contrary, they are dictated by a hearty concurrence with its objects, and by my firm conviction that nothing (public-houses alone excepted) retards the progress of temperance principles in London and other large towns so much as the want of greater publicity. Large numbers of people cannot at present be got together at frequent intervals to hear the claims of teetotalism set forth. The audiences at temperance meetings, with but few exceptions, contain the "public" or "outside" element (*i.e.*, non-teetotalers) only in the same proportion as Falstaff's bread bore to his sack. Most teetotalers like to attend their halls regularly, and so they themselves monopolise the bulk of the space. Now, in many provincial towns, the temperance hall is no misnomer, being one of the principal buildings in the place. Surely it is not creditable to London teetotallers that things are different here. The only place of any importance in which temperance meetings are held is Cambridge Hall, Newman street, Oxford street, but even that is somewhat out of the way. One large hall at least ought to exist in each of the metropolitan boroughs, and it should be located in the most public place possible. Some such ideas as these have long since occurred to some of the leading spirits amongst the 200,000 London teetotallers, and practical effect is about to be given to them by starting a joint stock company, having for its objects the erection and maintenance of temperance halls in London and the provinces. It will be managed by working men, and the shares (£1 each) will, it is expected, be speedily taken up.—I am, &c.,

A FRIEND OF PROGRESS.

THE ST. ANDREW'S CHURCH, HERTFORD, COMPETITION.

SIR,—In the early part of January last an advertisement appeared in your columns inviting architects to send in designs for the proposed new Church of St. Andrew, Hertford, which was to seat 600 persons, and the cost not to exceed £3,000. Competitors were advised to visit the site and make themselves acquainted with the prices of materials, &c., to enable them to make a design that could be carried out for the sum at the committee's disposal.

Various designs were submitted, from which the committee ultimately selected the plans prepared by Mr. Johnson, of Moorgate-street, who stated that his design could be carried out for £3,000, exclusive of the encaustic tile paving and some rich decoration he had introduced in his internal elevations. It appears, by a statement in the *Herts Mercury* of August 1, which I herewith forward you, that a meeting was convened to receive the tenders for the work, and that upon opening them the lowest tender was £4,360, and the highest £6,126, or more than double the architect's estimate.

The committee seem anxious to give Mr. Johnson every opportunity to carry out his plans if he can do so for the stipulated sum; but it is quite clear that the design cannot be carried out

for anything like the money, unless considerably altered or reduced.

Under these circumstances I think it most unfair to the other competitors that Mr. Johnson should be allowed six weeks to seek a builder (if possible) to carry out the works at the committee's price—viz., £3,000, after his utter failure to procure a public tender for a less sum than £4,360.

I have no personal interest in this matter, but as an architect I am anxious to see fair play in competitions, and so long as competitors are allowed to ignore instructions as to cost, &c., it is impossible that architects can compete fairly. It is much easier to design a costly building than it is to design a building at a limited cost with extensive requirements.—I am, &c., FAIRPLAY.

THE GAIETY THEATRE.

SIR,—By a report which appeared in your last impression of a case under the Metropolitan Building Act, relative to certain alterations now in progress at the Marylebone Theatre, Mr. Simpson, the builder, is reported to have said "That he was also the contractor for the new Gaiety Theatre, and the plans for that edifice, though similar to those of the Marylebone Theatre (so far as the point at issue was concerned), had met with the approval of the surveyor in that district." I am assured by Mr. Simpson that in this assertion he has been misreported; indeed, it is so contrary to fact that I feel bound to give such a report the most unqualified denial. I believe, with the exception of the Grand Opera and the new Vaudeville Theatre, at Paris, there is no theatre in Europe which has been constructed with such regard to prevention of fire—there will not be a wall or partition in the building of any other material than brick, no lintels in any of the walls, and, in addition to every corridor, passage, and staircase being of stone or concrete, the pit floor and the three tiers forming the balcony, upper boxes, and gallery will be all constructed of wrought iron and cement concrete, not a particle of wood being used, except only in the flooring boards. A double wire gauze curtain (on the principle of the Davy lamp) will close the opening between the stage and the auditory, so that if a fire were raging on the former not a spark and comparatively little heat could come through to the auditory.—I am, &c.,

CHARLES J. PHIPPS, F.S.A., Architect of the Queen's and Gaiety Theatres.

26, Mecklenburg square, W.C.

THE THAMES EMBANKMENT.

SIR,—I observe from a paragraph in "Engineering" of Friday last, that the engineer of the Thames Embankment Works is likely to receive a mark of royal favour upon the completion of these works. I presume that this means knighthood, and I have no doubt that it is for the architectural talent displayed in the arch at Temple-stairs, and the other works which you so pleasantly described in yours of August 28. Upon first reading your criticism I was somewhat astonished to find that you were not an admirer of the grand display of architectural talent to be seen on the Thames Embankment, and I could not make out why you should point out as absurdities so many things that the Spring Garden authorities think so very clever; but, of course, it was only a little pleasant banter, as you, of course, could not have any idea what was intended to be done to complete the arch which you have illustrated when you wrote. I will now enlighten you a little on this point. On the raised portion of the upper part it has been suggested that an equestrian statue of the Chairman of the Metropolitan Board of Works be placed; and the authorities having some doubts as to the strength of the arch to carry such a weight of taste, had the pier in the centre of the opening placed there, in case a shore should be required to shore up the keystone. I believe it has not yet been decided who is to have the honour of being represented on the lower part. I, therefore, suggest that the designer of the arch should be placed on one side in a suitable attitude, with a roll of drawings in his hand pointing to his mounted superior above; and on the other side—well, there will, perhaps, be room to accommodate all the admirers of this beautiful structure, so I would hoist them up to adorn it.—I am, &c., M. S. E.

Intercommunication.

QUESTIONS.

[1009.]—ADDRESS WANTED.—Could any of your readers inform me of the present address of Mr. H. J Austin, who gained the Pugin Travelling Studentship for either 1866 or 1867?—ALPHA

[1010.]—WALL FINISH FOR SMOKING ROOM.—I am erecting, in connection with an hotel, a room to be used as a smoking room, and occasionally as a public dining room. Its dimensions are 21ft. by 14ft. 6in., and 12ft. clear height. The walls I propose to matchboard "chair rail" high. Will one of your readers kindly give me the benefit of his experience, and suggest a moderately cheap and satisfactory manner of finishing the walls and ceiling, so that they may not become discoloured by smoke, and yet present a pleasing appearance? The usual way of treating such rooms about here is to cover the walls and ceiling with marble paper, varnished; but I should like, if possible, to do something different.—A COUNTRY BUILDER.

[1011.]—DURABILITY OF SLATES.—Can any of your readers give any information as to the durability of Port Madoc slates, and the actual difference between them and Bangor slates, and oblige?—A SUBSCRIBER.

[1012.]—CHIPPING CHISELS.—Will anyone tell me where to procure chisels of various lengths, such as a geologist would require for chipping off pieces of hard rock. They must be thoroughly well tempered.—S. W.

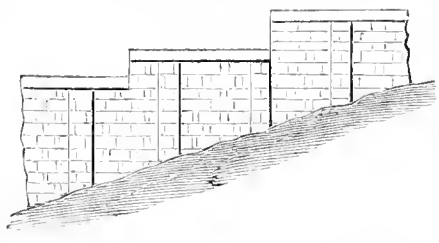
[1013.]—PARTY WALLS.—Allow me, through your "Intercommunication" column, to thank "Clerk" for his reply to my first question, and to express regret at not properly explaining the latter question, which should have read: A party wall having been pulled down, in which there was a small opening to give light to a cellar, has the proprietor, whilst reconstructing the wall, a right to place a much larger window in any other position he may choose? and having done away with the light to the cellar by the erection of the new wall, has he a right at any future time to reopen the light in its former position?—H. R. T., Hayling.

[1014.]—PORTLAND CEMENT FOR FIREPROOF FLOOR.—Will some of your subscribers kindly inform me, through the medium of your "Intercommunication" column, their experience in Portland cement as a finish to fireproof floors, and especially for warehouse purposes; and chiefly as to whether they are likely to cause condensation to any perceptible extent?—J. D. N.

REPLIES.

[984.]—FISH PONDS.—If carefully puddling the whole of the inside of the fish pond is not sufficient, "Francis R. Capon" can use asphalte, which would certainly make it watertight. I would advise him to carefully puddle it (i.e., work the clay up to the consistency of brick-making clay and line all the interior), and, if the sides are of too great a pitch, to work it carefully up, and make the sides in layers.—R.

[986.]—WALL BUILDING.—Allow me to inform "Contractor" that the elevation of his wall should be like what is shown in the accompanying cut. I have seen walls built



upon steep slopes falling to pieces owing to the fact of their having been built with the courses parallel to the slope of the ground. The courses should always be truly horizontal; and the wall has the better appearance for having the coping laid as shown. The top should be arranged in steps; although, if desired, the top course may have the bricks cut so as to be parallel to the surface of the ground. It is quite clear that if the whole of the courses be laid on the slope, the weight of the wall will be all thrown upon the lowest part, and must sooner or later burst it out.—T. M. S.

[987.]—TRUSS.—In the answer given by "Geo. H. Walters" in the BUILDING NEWS of the 4th inst., the square root sign in the formula is not put as it should be. Were it left unnoticed it might perhaps lead many into an erroneous calculation. It is put $T = \sqrt{H^2 + \frac{W^2}{16}}$, when it should be $T = \sqrt{H^2 + \frac{W^2}{16}}$. The figures .8125 are right, and bear the latter, which is the correct form. He is not correct in saying that the kingpost has a tensile strain equal to one ton. The only strain on a kingpost when the tie beam is horizontal is that which arises from the tendency of the beam to sag in the middle.—W., Tenby, South Wales.

[987.]—In the reply to this question, contained in your last impression, there seem to be some little mistakes that, for "A Beginner's" benefit, it is as well to set right. For instance, taking L = load on truss, T = half-length of tie beam, P = length of principal rafter, R = rise of roof, S = thrust at end of principal rafter, and F = strain at end of tie beam, I find—

$$S = \frac{20 \times 9}{5 \times 2} = 18\text{cwt.} = \text{thrust of rafter,}$$

$$F = \frac{20 \times 7.5}{5 \times 2} = 15\text{cwt.} = \text{tension of tie beam,}$$

while the strain on the kingpost, if framed as shown, would be one of tension; but the weight to be supported, simply by its own and that of half the tie beam, or (taking "G. E., Walters'" dimensions = say 3 cubic feet of fir at 40lb. $= \frac{120\text{lb.}}{2} = 60\text{lb.}$), a little more than half a cwt., instead of the ton he mentions; and the dimensions, if a kingpost be used at all in so small a span, might be—rafters, 3in. by 4in.; tie beams, 3in. by 5in.; and kingpost, below head, 3in by 3in. But, for the small span given, and to do away with an unnecessary amount of framing, I should feel more disposed to make the rafters 4½in by 2½in., with a collar 9in by 2½in. securely nailed to them about halfway up the rise of roof, and have no king at all. At all events, that portion of the frame is very slightly required; a ½in. iron rod would answer all the requirements as well. —A SUBSCRIBER.

[988.]—GYMNASTIC ARRANGEMENT.—From the question, the strain upon the rod A is twice that upon each of those B and C. We may proceed practically to work out the question, as follows:—Suppose a man to be swinging upon each of the ropes B and C, and we may put his weight at a hundredweight and a half. If we find the dimensions of B they will answer also for C, and doubling them will give us the size of the rod A. Bearing in mind that the rods are subjected to violent jerks and shocks, which are very difficult to calculate accurately, a liberal allowance must be made in the material. Let us assume the greatest weight that could come upon either of the rods B or C to be a couple of cwt., and if we make our working load to be one tenth of the breaking, we shall have to provide for a breaking strain of one ton upon each of the rods B and C, and two tons upon A. All these rods should be of wrought iron which material will bear safely five tons per every square inch of sectional area; and, therefore, the area of rods B and C should contain one-fifth of a square inch, and A two-fifths. Now, putting A^1 for the area, and D for the required diameter, we have, algebraically, $A^1 = \frac{\pi D^2}{4}$, but $\frac{\pi}{4} = 0.7854$, and $A^1 = \frac{1}{5}$, so that we have $\frac{1}{5} = 0.7854 \times D^2$. Solving for D, we obtain $D = \sqrt{\frac{1}{5 \times 0.7854}} = \frac{1}{\sqrt{5 \times 0.7854}} =$ practically $\frac{1}{2}$. The rods B and C may therefore be ½in., and the rod A 1in. in diameter. The crossbeam D E may be 4in. by 2½in.—W.

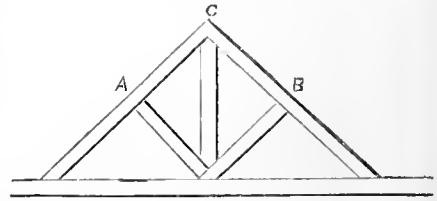
[989.]—MAGNETISM.—Soft iron may be converted into a temporary magnet very readily. One of the simplest means is to rub it longitudinally with another magnet, taking care to keep the friction always in the same direction. Another, but slower plan, is that of simple induction where the iron to be magnetised is held between two magnets, with their poles placed in opposite directions, as

shown in the drawing. A poker or pair of tongs can be rendered temporarily magnetic by simply holding them in the direction of the magnetic meridian, and striking them upon the other end with a hammer or stone. It should be borne in mind that soft iron is only rendered a temporary magnet by these means, but steel is rendered a permanent one; but it is a much more difficult task to effect, and cannot be satisfactorily accomplished without the aid of electricity.—STET.

[990.]—PRESERVING TIMBER.—"S. T. L." should purchase the timber he wants ready creosoted; or, if he prefers it, he can send balks to be prepared especially; but the former is the cheaper, and in every way the preferable plan. It is always better to buy any ordinary scantling that is used than to have any unusual size done, especially unless there be a great quantity of it.—AXEMAN.

[991.]—STEAM POWER FOR SAWMILL.—The power "Sawdust" would require is so limited that the charge could not be regulated upon the same principles that guide those made for portable or stationary steam power. He must make an arrangement with his neighbour.—S. N.

[992.]—HIGH-PITCHED ROOF TRUSS.—I have often braced roof trusses of the kind mentioned in "Intercommunication" by inserting a couple of strong struts, A and

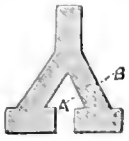


B, about 6in. by 4in., and a king rod, C D, of about the same scantling; or this last may be advantageously made of round iron, ¾in. in diameter.—CARPENTER.

[992.]—In reply to "Yorkshire Student," he can purchase the work "Norman Shaw's Sketches" if he will correspond with W. P., 13, Buckingham-row, Westminster, S.W.

[993.]—STUDENT'S GUIDE.—The cost of the book is 1s., and it can be procured from Weale, High Holborn. It is one of his excellent rudimentary series.—APPRENTICE.

[994.]—LOAD ON CAST-IRON SKEWBACK GIRDERS.—Will you allow me to ask "Urgent," in reply to his question what is the object of making a girder in so extraordinary a form? It does not appear to have any top or bottom flange, and is, in fact, the only specimen I ever saw of the kind. Taking it as it is, I should suppose that under a breaking load it would yield somewhere in the direction of the line A B. I should be inclined to take the sectional area of one of the sloping pieces, and work by Mr. Hodgkinson's formula. Putting W for the breaking weight in tons at the the centre, A for the area in square inches of the sloping flange, D for the depth in feet, and L for span also in feet,



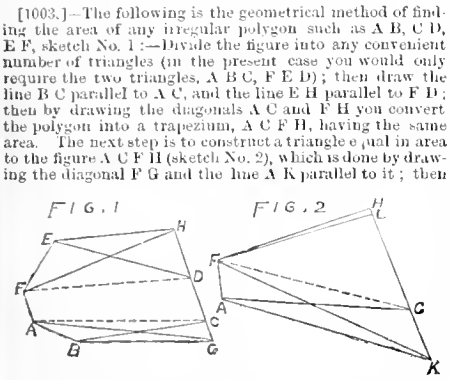
we have $W = \frac{A \times D \times 26}{L}$. The girder shown is about the worst form in which it would be possible to distribute the material.—CAST IRON.

[997.]—IRON IN IRON ORE.—Your correspondent should have given the name of the iron ore, as there are a great many varieties. There is the common ore or ironstone, which is mostly a carbonate; there are the red and brown hæmatites, the spathose iron ore, the specular, and the sulphide, or well known iron pyrites, and others of less notoriety and value, some of which are known only to the chemist. If "Iron" will let me know what particular ore he means, I will endeavour to tell him how to analyse it.—MINERALOGIST.

[1001.]—PLAN DRAWING AND ARCHITECTURE.—I would advise "Stonemason" to get "Gwilt's Encyclopædia of Architecture," published at £2 12s. 6d.; not that it contains a complete system of lines for stone cutting, but it does give you a knowledge of plan drawing and architecture.—R.

[1003.]—AREA OF A FIELD.—There is evidently some mistake either in the admeasurements or the figure. I see in the triangle B F C the side F C is greater than the other two together, which of course is an impossibility (Euc. i. 20); so, also, in the triangle A F B, the two sides A F, A B are together less than F B; while in the irregular figure C F E D the sum of the three sides F E, E D, D C is less than the one side F C; and equally wrong and for the same reason are the figures A F C B and A D C B. It is utterly impossible to construct a figure with the dimensions given; but if "Young Surveyor" will correct them I am willing to give the required information.—J. M'NAMARA

[1003.]—The following is the geometrical method of finding the area of any irregular polygon such as A B, C D, E F, sketch No. 1:—Divide the figure into any convenient number of triangles (in the present case you would only require the two triangles, A B C, F E D); then draw the line B C parallel to A C, and the line E H parallel to F D; then by drawing the diagonals A C and F H you convert the polygon into a trapezium, A C F H, having the same area. The next step is to construct a triangle equal in area to the figure A C F H (sketch No. 2), which is done by drawing the diagonal F G and the line A K parallel to it; then



draw the line F K, which gives the hypothenuse of triangle K H F, and this triangle is equal to the polygon A B C D E F. The formula for getting the area of any triangle is as follows:—Let K H = base, and L F = a line drawn from the vertex of the triangle perpendicular to K H, then $\frac{K H \times L F}{2}$ = area. If it is not convenient to convert the figure into one triangle, the only way is to divide it into a series of triangles, then get the area of each and sum them together. I would advise "Young Surveyor" to study "Binn's Elements of Geometrical Drawing," or any elementary work on that subject.—S. H.

[1003.]—"Young Surveyor" is either sadly in error or is asking for the solution of an imaginary problem. If he will take the trouble to look at the question he will at once see what an absurd calculation he requires; and before proceeding further, allow me to remind him that the editor, and we, the subscribers, require questions of practical difficulty. It is obvious that the two sides A F and A B, each 96ft., are less than the third side F B, 210, which is absurd; and again, F B and B C 210 and 730 = 940, less than F C 1370; and more than that, supposing the figures to be right, he wants the dimensions E G or D B to work it out by figures. When he has got the requisite dimensions, he can obtain the area by the following:—Divide the figure in triangles and parallelograms, and find the areas of each separately. To find the area of a triangle proceed as follows:—Take the triangle B F E in his figure; B F = 210, F E = 165, and E B = 320.

$\frac{1}{2}(210 + 165 + 320) = 347.5.$

$347.5 - 210 = 137.5 \qquad 347.5 - 165 = 182.5.$

$347.5 - 320 = 27.5.$

$\sqrt{(347.5 \times 137.5 \times 182.5 \times 27.5)}$ = area of triangle.

Or, to give the rule in words, "From half the sum of the three sides subtract each side severally; multiply the half sum and the three remainders continually together, and the square root of the last product will be the area."—R

[1003.]—It is very evident that "Young Surveyor" could not have measured such a piece of land as stated, for the simple reason that there never was and never could be a piece of land of such a form, and bearing such dimensions. To proceed: If "Young Surveyor" had but made himself acquainted with Euclid, book i., prop. 20, he could not possibly have fallen into so egregious a blunder; for since any two sides of a triangle are together greater than the third side, F E + E D are greater than F D. Again, for a similar reason, D F + F A are greater than D A; much more, then, are D E + E F + F A together greater than A D, which, according to "Young Surveyor's" proposition, they decidedly are not.—T. E. WOODHOUSE, Leicester.

[Other solutions of the problem have been received from "A Surveyor," "J. N. Crofts, Liverpool," and "R. L. B."]

[1007.]—CEMENT FOR GAS AND WATER PIPES.—The following is a cement, the formula for which I fell across lately, and which I find very good:—Mix six parts of finely powdered graphite, three parts of slaked lime, and eight parts of sulphur with seven parts of boiled oil. Knead well till the mixture of all the ingredients is perfect.—E. J. K

WAGES MOVEMENT.

THE working classes of America, who rejoiced with exceeding great, but as it turns out, with untimely joy over the passage of the recent law by Congress enacting that eight hours of labour should constitute a day's work in the Government dockyards, &c., have received a sad disappointment. They had imagined that the Government would continue to give the same wages for eight hours' work as had been paid for ten hours; but it appears that the Government does not see it "under those lamps," as Artemus Ward was wont to say. General Rodman, who commands the United States' Arsenal at Rock Island, having doubts as to the proper construction to be put upon the law, telegraphed for instructions to the Secretary for War, who replied that, in his opinion, the law did not provide that ten hours' pay should be given for eight hours' work, and that, until Congress directed to the contrary, he should order 20 per cent to be deducted from the wages which the men had been receiving. Under this ruling, the "boon" of the eight hour law is a curse, since the mechanics who were receiving 40dols. 50c. per day now get but 32dols. 60c.

Messrs. John Crossley and Sons, the great carpet manufacturers of Halifax, having contemplated the shortening of the hours of labour on Saturdays, but no wishing to do so without the approval of the men themselves, recently resorted to a somewhat novel expedient for settling such questions. Tickets were issued for a ballot, white tickets being for the proposed alterations, and blue for keeping things in *statu quo*. The votes recorded were as follows:—white tickets, 3,971; blue, 664; majority for the change, 2,307.

The fifty-eighth annual report of the Friendly Society of Ironfounders, a thick volume of 172 closely printed pages, records the proceedings of the society for 1867. Including a considerable amount of cash in hand, the income for the year was £72,798, and the expenditure £63,949, leaving a balance of £8,849. The financial position of the society at the commencement of the present year exhibits a decrease in its cash balance of about £20,000 when contrasted with the corresponding period of 1867. This large falling off arises from the great depression which has prevailed in the trade all through the past year. In consequence of this depression a large number of the members were thrown out of employment, and the sum expended in their relief was quite unparalleled in the history of the society. Upwards of £35,470 was paid away under this head in 1867, being an increase of £20,395 over the amount applied to the like purpose in 1866, and far in excess of any previous year's payments on a similar account. The total expenditure, which includes superannuation, accidents, funerals, and the promotion of emigration, was £15,838 for the direct benefit of the members of the society. There are 10,839 members.

At the general meeting of the Birmingham Trades Council held on Thursday week a deputation from the Liverpool bricklayers attended to lay a statement of their case before the council. The deputation alleged that the men were on strike for a set of rules which the masters were improperly attempting to force on them. It was resolved to give credentials to the deputation, and to recommend the case to the various societies for assistance and support.

The workmen in the bronze chasing and mounting establishments in Paris have struck work on account of insufficient pay.

The loss to the New York bricklayers in wages during the five weeks of their strike is estimated at 30,000 dollars. The strike still continues.

A movement is on foot amongst the ironworkers of the north of England to obtain an advance on the wages they have been receiving for the last year and a half. Following the long strike of 1866 was a great reduction of wages, amounting to 25 or 30 per cent. Even with this advantage in their favour masters have complained down to the present time that they cannot meet foreign competition, and the assertion has been partially borne out by the fact that only very partial employment has been afforded generally in the trade until a short time since. A meeting of delegates was held at Darlington on Saturday. The proceedings were private, but the resolution passed at the meeting has been published, which reveals that an attempt is to be made to obtain an advance of about 10 per cent. on puddling and mill work, and that deputations are to wait on masters to this end. Another meeting is to be held at Gateshead in a fortnight, to receive a report of what is the employers' answer. This attempt, which the union would wish to make national, is looked upon throughout the northern district as most rash and ill advised, and one to which the employers will under no circumstances yield.

STATUES, MEMORIALS, ETC.

THE group by M. Aimé Millet, intended to crown the new Opera house in Paris, has been cast. It represents Apollo erect and holding the lyre in outstretched hands. By his side are seated the muses of drama, music, and of dance.

The old Burgh Cross, which was fixed in the wall of a house on the south side of the High street, Dunfermline, and where it has been for many years, has been removed and erected on a substantial pedestal in front of the County Building. The decorations on the structure were finished on Saturday. The erection has been promoted chiefly by Dr. Henderson, Mr. Joseph Paton, and other antiquarians, and the expense defrayed by public subscription.

Subscriptions are now being asked in order to defray the expense of erecting a monument to Foxe, the "martyrologist," at Boston, Lincolnshire, his birthplace. Foxe is buried in Cripplegate church, and died in 1587.

A veteran French sculptor, M. J. Louis Gardie, who is upwards of seventy, and served under the first Napoleon, having settled at Brighton, is desirous of presenting to that town a large bas relief of the great Emperor, and a bust, in terra cotta, of Captain Speke. Curiously enough, though a Frenchman born, and one of Napoleon's guard, he was employed just fifty years ago by Messrs. Rundell and Bridge upon the celebrated "Wellington shield."

Mr. George Moore has offered to the inhabitants a memorial fountain to be erected in the Market-place. For above four years past Mr. Knowles has been working at the design. A drawing of it was exhibited at a recent meeting and was much admired. It is square, and stands on a base of little above 14ft. square. Its total height is 30ft., and it finishes with a massive bronze and gilt cross, surmounting a tapering spire. It is to be built of granite, rough hewn and polished, the upper part of it being boldly chiselled, with a floreated design. The principal feature will be the body, in the four sides of which four white marble basso relievi are to be placed. These relievi will be about 3ft. square, and are to be sculptured by Woolner. The drinking fountains are to be four in number, one on each side, and are to be placed about 3½ft. from the ground. There will be polished granite basins below each stream of water, and the surplus water will run by a pipe to receptacles below, so that basins may be kept filled with water for horses, dogs, &c.

STAINED GLASS.

THE west window of the parochial nave of St. Helen's, Bishopsgate, has this week been filled with stained glass, in memory of the late Mr. Alderman Copeland, at the cost of various friends and inhabitants of the ward of Bishopsgate.

A stained glass window has just been placed in St. Mary's Church, Bury St. Edmunds. The lights below the transom are occupied by one subject—The Last Supper, and the upper lights are filled with representations of SS. Mary and Joseph at the inn at Bethlehem; the Adoration of the Magi, and the Flight into Egypt. The window is from the works of Mr. H. Hughes, of London.

A new stained glass window is about to be inserted in the south window of the Parliament House, Edinburgh. The artists employed on this work are, we believe, the Chevalier Maximilian Ainmüller, inspector of the royal glass painting establishment at Munich, and Von Kaulbach, an artist of remarkable power. The subject illustrated is the inauguration of the Court of Session by James the Fifth, in the year 1532.

BUILDING AND LAND SOCIETIES.

THE annual meeting of the Chatham Building Society was held at its offices on Thursday last. The receipts for the year, inclusive of a balance of £2,601 from last year, have been £21,747. The advances were £14,245; realised shares, £1,290; withdrawals, £2,169, there being a balance of £2,210. The gross profits amounted to £3,091, leaving a balance of £2,224, after deducting £867 for expenses and interest paid. A dividend of 6 per cent. on unalletted shares was declared.

The eighth annual meeting of the Stafford Mutual Investment and Building Society was held in the Guildhall, Stafford, on Thursday week. The society now consists of 239 shareholders, holding 711 shares, 420 being original, and the remainder taken at various dates. Beyond these the society has £4,750 as investments, which will be repaid as the funds of the society came in. The secretary stated that during the eight years past the society had received over £56,000, which had been applied in advances and withdrawals. Mr. Austin and Mr. Anderson were re-elected directors, and Mr. Hilston, Mr. T. Hopper, Mr. W. Wynne, and Mr. J. Woodhouse were elected to supply extraordinary vacancies. Mr. E. Lloyd was re-elected auditor on behalf of the shareholders. Votes of thanks were unanimously accorded to the directors, the auditors, and the chairman for the services rendered.

The fourteenth half-yearly meeting of the London Labourers' Dwelling Society (Limited) was held on Monday last. The directors presented their report for the six months ending June 30, which was received and adopted, and the usual dividend at the rate of 5 per cent. per annum free of income tax was declared. The capital of the society now amounts to £33,400, the sinking fund (for the redemption of the leasehold property of the society) to £1,026, and the reserve fund (for the equalisation of dividends, or extraordinary expenses) to £3,995, of which sum £2,000 is deposited at interest in order to provide the means of purchasing temporarily at par any shares that a member may from unforeseen circumstances wish to realise.

LEGAL INTELLIGENCE.

IN our last impression we gave a report of some proceedings at the Marylebone Police court relative to the alterations now going on at the Marylebone Theatre. The magistrate, it will be remembered, decided in favour of the district surveyor, stating that he would give his reasons for such decision on a future day. Accordingly, on Thursday week, Mr. D'Eyncourt at some length stated the grounds upon which he had formed his opinion, and quoted various clauses in the Building Act in favour thereof. The first question was whether the alterations to be made would bring them within the cognizance of the district surveyor. The 10th section of the Act said "that whenever any old building has been taken down to an extent exceeding one-half of such building, such half to be measured in cubic feet, the rebuilding thereof shall be deemed to be the erection of a new building. [It was said the alterations would not amount to one-half.] Mr. D'Eyncourt was of opinion that the proposed alterations would bring it within the section of the Act he had quoted, as there appeared to be more being done than could be considered as necessary repairs. He, therefore, called upon the builder to comply with the orders of the district surveyor. Costs, to the amount of £5 7s. were allowed. A case for one of the superior courts was asked for, a request which the magistrate has under consideration.

At the Wakefield Courthouse on Wednesday week, Mr. Samuel Green, a member of the Town Council, was sum-

moned for a contravention of one of the building bye-laws of the borough. The town clerk, who conducted the case, said the proceedings were taken under the bye law of the Local Board relative to new buildings, which renders any person making any alterations in plans which have been approved of by the Local Board liable to a penalty of £5 In February last plans were sent in by Mr. Thomas Craven for the erection of four dwelling houses and shops, and were approved of by the board. In these plans provision was made for a kitchen containing slop stone and boiler in the back room on the ground floor, and a meat and coal cellar and pantry on the basement story, which was 6ft. 6in in height. On the borough surveyor making an examination of the premises, he found that the boiler and slop-stone had been removed into one of the low rooms, which had thereby become converted into a habitable room; and by the fifteenth bye-law all habitable rooms must be 8ft. in height.—Mr. Crutchley, the architect of the houses, here stepped forward and said that he was the real defendant, as Mr. Green had only worked to plans furnished by him (Mr. Crutchley), and, therefore, he absolved him from all responsibility. He submitted that whatever alterations had been made were quite beyond the province of the Local Board to regulate. A clerical error had crept into the plan, one of the low rooms being designated a meat-cellar instead of a scullery, but he contended that the scullery was not and was never intended to be a habitable room, never having been finished off as a habitable room would be.—Mr. Lynam, the borough surveyor, was now called, and stated that had a plan with the alterations been submitted to him he should have advised the committee not to approve of it, because, in his opinion, the room would have come under the definition of a habitable room, and, therefore, should have been 8ft. high. A fine of £2 and costs was inflicted on Mr. Green.

ARBITRATION CASE.—On Wednesday, the 18th ult., Mr. E. Waugh, of Cockermouth, heard (as arbitrator), at the Station Hotel, Holborn-hill, Cumberland, a case in which Messrs Bradley and Myers, builders, Newtown, Millom, are plaintiffs, and Messrs. M'Gowan, timber merchants, Whitehaven, are defendants. The case, which had been referred from the Court of Queen's Bench, was brought to recover the sum of £80 odd, the balance of an account alleged to be due plaintiffs by defendants. Mr. Thomas Postlethwaite, solicitor, Ulverston, appeared for the plaintiffs, and Mr. Mason, of Whitehaven, for the defendants. It was agreed that the £80 claimed by plaintiffs should be admitted, the question for the arbitrator being whether the defendants could substantiate a set-off equal to that amount. It appeared that plaintiff's claim was for £81 11s. 7½d., balance of account, which the defendants refused to pay, alleging that they had a claim of about the same amount for timber supplied to Mr. Thomas Sayers, a joiner and builder, either at the request of the plaintiffs, or under their guarantee, or otherwise, and of which plaintiffs said they knew nothing, at all events they denied getting the timber for which the defendants now charge them. Evidence was heard at great length, and the arbitrator has deferred his decision.

Our Office Table.

In connection with the widening of Wilderness-row, mentioned by us a few weeks since, the local authorities contemplate the purchase of a portion of the Charterhouse grounds for the purpose of forming a public recreation ground similar to that about to be provided at Poplar.

Howard's patent safety boilers are rapidly coming into use, and are spoken of very favourably. Many have already been fixed at Birmingham, and two others are about to be fixed at the Birmingham Waterworks.

At the last meeting of the Rotherhithe Vestry Mr. Kelsey was appointed as consulting surveyor, at a salary of £100 per annum, and it was decided to appoint a surveyor of pavements, at £200 a year.

The greater portion of the property required for the additional buildings for the General Post Office has been acquired by the Postmaster General. The new buildings will be situated at the corner of Newgate-street, and, therefore, on the opposite side of St. Martin's-le-Grand to that occupied by the General Post Office. The property required for the purposes of the new buildings is situate in St. Martin's-le-Grand, Bath street, Newgate-street, and Angel-street. No part of Newgate-street, Bath-street, or St. Martin's-le-Grand is to be stopped up. Bath-street is to be widened, and carried out so as to form a junction with Angel-street. This street is to be not less than 20ft. wide throughout. The work of clearing the site for the new buildings will be carried out as rapidly as possible. It is stated that a portion of the new premises will be devoted to the management of the new system of postal telegraphy.

On Monday, the thirty-eighth anniversary of the Operative Stonemasons' Society of England and Wales was held at Huddersfield. It was stated that the funds of the society were disbursed for trade and benevolent purposes. The balance in hand was £13,370. The total number of members was 18,628, of whom 2,356 were both sick and trade members. The members admitted during the year numbered 3,163; and the expenditure for the same period had been £24,807.

A new bridge across the Earn at Crieff has now been finished at a cost of several thousand pounds. It was built under the superintendence of Mr. Alexander Hair, of Edinburgh, and is a handsome and commodious structure compared with the old bridge, affording ample accommodation for all descriptions of vehicles, besides a broad footway on the east side for pedestrians. The bridge contains four arches extending to a span of 42ft. each, and the parapets are fully 100 yards in length.

A meeting promoted by the Council of the Midland Institute for the establishment of a trade school in Birmingham was held in that town yesterday week, Mr. William Kendrick in the chair. The Mayor, Mr. George Dixon, M.P., Mr. Arthur Ryland, and other gentlemen, spoke in favour of the project, and ultimately the following resolution was passed:—"That this meeting approves the scheme now submitted, and recommends that it be adopted by the Midland Institute, and that an appeal be made to the town for the necessary funds—namely, £250 for immediate expenses, and a subscription list of £400 per annum, and that upon these funds being provided a school shall be established." A liberal subscription was commenced.

Yesterday week workmen commenced operations in Dorset-street, Fleet-street, for the formation of an entrance to the intended volunteer ground, situate on the spot where Bridewell Prison and Hospital formerly stood.

The water has at length found its way once more into the Regent's Park lake, the bottom and sides of which have been cleansed and reconstructed, with a view to the prevention of loss of life in the "skating season." The sewage of the Theological College now finds its way into a sewer, and thus the water of the lake is able to maintain its pellucid appearance. Arrangements are made for emptying the lake, if necessary, in a very short time.

The *Edinburgh Courant*, referring to the death of George Mac Callum, a promising young sculptor, says:—"Several years ago young Mac Callum's very remarkable talents attracted the attention of Mr. David Bryce, Mr. John Steell, Dr. Burt, and other influential citizens, and during the intervening period his time was fully employed. In the sculpture room of our annual exhibition his works occupied a very prominent place. During the past few months he had completed a good many busts, which will probably be shown at the next exhibition of the Royal Academy. At the time of his death he was busily engaged on one of the groups for the Albert Memorial, and also on a model design for the contemplated statue of the late Sir David Brewster, for which he was one of the three selected competitors. His statues and medallions in the hall of the College of Physicians, Queen-street, executed last winter, have been greatly admired."

A piece of very "sharp practice" is said to have been recently achieved by a speculative builder, not a thousand miles from Wandsworth. He sold a batch of houses, one of their recommendations being that gas-pipes were fitted in in preparation for the mains being laid down in the front street. It subsequently turned out that a few inches of piping had been stuck through each of the ceilings.

An impudent theft has just been perpetrated at the Exhibition of the Society of British Artists, Suffolk-street, Pall Mall. A person called with a note purporting to be from Mr. J. Kennedy, of Kidderminster, requesting that a picture painted by the latter might be given up to him. The picture was handed over to the bearer of the note, which now turns out to have been a forgery.

The first annual meeting of the Wakefield Industrial and Fine Arts Institution was held on Friday week last, at the museum of the institution in Bell-street. From the report, read by Mr. Dixon, the secretary, it appeared that of the £1,356 16s. 10d. which was in the treasurer's hands, £21 had been received in subscriptions. Mr. H. Lee had promised a prize of £5 annually for excellence in drawing. Mr. Walter Smith (head master) considered that satisfactory progress had been made by the pupils. The report was adopted.

The Taunton Museum now contains—deposited there by Mr. E. Jeboult, surveyor, Taunton—original copies, in five volumes, of the surveys of the manor of Taunton Deane, made at the time of the Commonwealth.

On Saturday week the new iron bridge just erected at Wickham Market was formally inspected. The bridge is 36ft. in span, and is about 26ft. wide, and was designed by Mr. H. M. Eyton, architect. The contractors were Messrs. Whitmore and Binyon.

It has been suggested by a correspondent that swimming baths, similar to those in Sweden and Denmark, should be constructed. What is wanted, he says, is to have a large enough part of the water enclosed by wooden erections, which should be divided into separate rooms on all sides of the enclosure. He sees no reason why such baths should not be made in the waters of all the London parks, and he believes they would all pay well.

Mr. George Watson, of the firm of Watson and Baker, Southwark Bridge-road, and Shadwell, has undertaken to procure water at almost any depth by his newly patented "artesian well tube," and an experiment is about to be tried before a number of the most eminent scientific gentlemen connected with Her Majesty's Government, on the grounds attached to Richmond Villa, Upper Plaistow, when the principal residents in the district will be admitted by tickets, which can be procured on application to the proprietor.

The Congress of the International Association of Workmen, sitting this week at Brussels, has adopted resolutions, declaring that workmen cannot be completely emancipated by means of strikes; that it is necessary strikes should be regulated by a code of rules; that it is necessary to organise societies of resistance for all trades and in all countries where such do not yet exist, and to establish a connection of such associations with each other; and, further, that councils of arbitration should be instituted. Mr. Lucraft attended the Congress as the representative of English workmen.

Clement's Inn, one of the Inns of Chancery attached in name to the Inner Temple, and formerly the nursing-place of some of our best lawyers, is in course of demolition, the site being part of that required for the new Law Courts. Nothing very remarkable, from an art point of view, is attached to the place, if we except the sun-dial in the middle of the garden, which is supported by the kneeling figure of a naked Moor or African, of some merit. It was brought from Italy by Lord Clare, by whom it was presented to the society. The figure is worthy of preservation, and might be removed with advantage to some more public position.

Mr. Dewhurst, one of the borough magistrates of Bradford, is erecting an arcaded market for the benefit of a district where such a market is needed. Six successive plans were drawn by the architects, Messrs. Lockwood and Mawson, but each time the requirements were extended by the local board, as, for example, in regard to the breadth of the street and the arcading. One bye-law stated that "Every new street, not being a carriage road, shall be laid out and formed at least 24ft. wide, and there shall be one entrance at least to every such street, of the full width thereof, and open from the ground upwards." As to the breadth of the street, the local board, in the face of their own bye-law, insisted, successively, on 36ft., and even 42ft., to which the plans were actually altered. Mr. Dewhurst being advised that "open from the ground" in the bye-law as it stood referred to the entrance and not to the street, at last proceeded with his market in defiance of the corporation, who cited him before the local magistrates; but they have just dismissed the case, after full and repeated hearing.

An exhibition of articles lent from the National Museum at South Kensington was opened on Monday, at the Corporation Art Gallery, Ratcliff-place, Birmingham. During the day about eighteen hundred persons, many of them workmen, availed themselves of the opportunity of inspecting it. The collection includes a portion of the famous Castellani jewellery (bought at the Paris Exhibition), a quantity of other jewellery, and examples of ornamental art in silver, bronze, pewter, and iron. The whole is arranged in ten cases, in a manner adapted to the convenience of students, and each article bears an explanatory label, so that no catalogue is required. To the loan collection, by the courtesy of the Council of the Midland Institute, is added the collection of enamels given by the late Sir Francis Scott to the Institute.

Patents for Inventions

CONNECTED WITH THE BUILDING TRADE.

3596 J. MURRAY. IMPROVEMENTS IN THE CONSTRUCTION OF ROADS OR STREETS. Dated December 18, 1867.

This invention consists in first preparing the under surface. The inventor then lays down upon this surface a series of longitudinal timbers, and, if necessary, these timbers may be bolted or otherwise fastened to one another. Upon these timbers he sets the usual granite or other paving, natural or artificial asphalte or other material being laid between the stones and the timber, and also between the stones themselves, so that the stones are covered on every side except the upper surface, or that surface exposed to traffic, by such asphaltic or other material.—Patent abandoned.

3687 W. FRYER. IMPROVEMENTS IN SELF-CLOSING TAPS. Dated December 28, 1867.

In making a self-closing tap according to this invention the inventor takes any kind of tap which can be opened and closed by the motion of its axis through about a quarter of a rotation, and he fixes the said tap in a box or chamber made, by preference, of cast iron, the ingress and egress pipes passing through the sides of the said box to the tap. To the axis of the tap he attaches an arm or lever, and connects to the end of the said arm or lever one end of a spring of vulcanised india-rubber, or a coiled steel spring, the other end of the spring being connected to the side of the box or chamber. The said spring tends to keep the tap in its closed position. To the end of the arm or lever, a rod, chain, or cord is attached, the said rod, chain, or cord, being in a line with the spring described, but on the opposite side of the arm or lever. The free end of the said rod, chain, or cord, passes through the side of the box or chamber, and terminates in a knob or handle. In using the tap, the knob or handle is pulled, when the axis of the tap is opened, and water or liquid allowed to flow. On loosing the knob or handle the spring pulls back the arm or lever and closes the tap.—Patent abandoned.

3695. E. T. BELLHOUSE. IMPROVEMENTS IN THE CONSTRUCTION OF FIREPROOF FLOORS FOR BUILDINGS. Dated December 19, 1867.

Here the beams, skewbacks and tie-rods are arranged in the same way as for the ordinary arched floors in mills and warehouses, the beams being either cast or wrought iron or other material. Instead of a segmental centering usually employed, the inventor makes use of a flat board or stage to support the bricks which are set obliquely from each bevelled side of the beam or skewback, or from specially made bevel bricks or blocks, the lowest angle of the bricks resting upon the wooden board or stage. When the bricks are set from each side nearly to the centre, the triangular space which is left between the bricks in the centre is filled up with triangular bricks or blocks. When the brickwork is sufficiently set, the stage is removed, and the ridges left on the upper surface of the oblique position of the bricks are covered with concrete, cement, asphalte, or other material, to make a level surface forming the floor. The rigid surface of the bricks below can be plastered over to make the ceiling.—Patent abandoned.

3620 B. MONSON. IMPROVED APPARATUS FOR SLIDING THE SASH FRAMES OF WINDOWS, AND FOR SLIDING SHUTTERS.—Dated December 19, 1867

Here the inventor lets into the side of the window case or frame an apparatus for governing the rate of movement of the sash to prevent its being moved with too great rapidity, and such an apparatus may consist of a frame containing a reel or barrel and spring fusee arrangement (or the mechanical equivalents thereof), winding and unwinding a cord or chain, the spindle of the reel or barrel being provided with a toothed wheel gearing with another toothed wheel which projects through an opening in the said frame and acts on a rack on the edge of the sash frame, a cast iron rack being let into each side of each sash, and the apparatus above described being inserted into each side of the window case or frame so that the toothed wheel which projects through the frame and acts on the rack in the sash frame shall be about half an inch lower than the top of the inside sash, the window being put in at the top and slidden downwards.—Patent abandoned.

3623 E. FIELD. AN IMPROVED CHIMNEY COWL FOR CHIMNEY TOPS.—Dated December 20, 1867.

Here the chimney top is provided with a loose cap, the lower edge of which extends somewhat below the upper edge of the chimney top, and this cap is supported by a shaft, spindle or arms, so that the effect of the wind blowing in any given directions against the side of the cap will be to force that side of the cap against the chimney top, and so protect the latter from any undue action of the wind, and thus permit the uninterrupted exit of the smoke at the other side between the upper edge of the chimney top and the lower edge of the cap.—Patent abandoned.

3689 W. E. NEWTON. IMPROVEMENTS IN BUTT HINGES. (A communication.) Dated December 28, 1867.

This invention relates to the peculiar manner of constructing butt hinges for doors which swing or open both ways. This improved construction of hinge folds into itself, it being a reversible rabetted hinge. This invention further consists in forming a butt in such a manner that it shall be a three leaf butt, folding into itself, two of which folds placed together will form a single butt, and will work alternately as the door swings back and forth from the centre. The invention further relates to the manner of attaching the butt to the door and casing, and in the device for muffling the sound and for rendering the door self-closing or automatic in its back movement towards the centre.—Patent completed.

3694 E. EVANS. IMPROVEMENTS IN THE CONSTRUCTION OF THE SASH FRAMES AND BOXINGS OF WINDOWS AND SHUTTERS, AND IN THE MODE OF HANGING THE SASHES OF WINDOWS. Dated December 28, 1867.

First, as regards sash frames, the inventor proposes to make the boxings thereof hinged or sliding, instead of fixed, as commonly practised, so that by simply turning such parts on their hinges, they may be opened and access had to the sash weights and lines for connecting them together when required; or the boxings may be slidden into grooves as panels and removed when required, or be otherwise attached to the sash frame so as not to be fixtures; and he proposes to connect the sashes of the window to the sash lines by affixing a hook to each sash line, which hook takes into a hole formed in a piece of metal let into the edge of the sash, so as to be flush therewith. He employs parting beads of the ordinary kind to keep the sashes separate.—Patent abandoned.

3666 C. CHURCHILL. AN IMPROVED GAS BURNER. (A communication.) Dated December 28, 1867.

This invention consists, chiefly, in a novel construction and arrangement of the parts of a gas burner, by which the gas and air are well heated before coming in contact with the flame, thereby securing the most perfect combustion; also in a peculiarly formed cock and an independent supply aperture, whereby a small flame is kept burning when the main flame is extinguished; thus, with trifling additional cost, avoiding the annoyance of relighting, and the danger arising from the escape of unconsumed gas.—Patent abandoned.

3708. M. A. F. MENNONS. AN IMPROVED MODE OF ACCELERATING THE INDURATION OF CERTAIN DESCRIPTIONS OF CONCRETE OR ARTIFICIAL STONE. (A communication.) Dated December 31, 1867.

This invention consists in the application of carbonic acid gas as a means of accelerating the induration of concrete or artificial stone composed of lime and sand or other siliceous matters.—Patent completed.

3713 V. I. DAGUZAN. IMPROVEMENTS IN THE CONSTRUCTION OF PAVING. Dated December 31, 1867.

These improvements consist in the construction of a level road or causeway, or horizontal across, as described. It is formed of flags or slabs composed of a grating or frame, made of wrought or cast iron, in the apertures of which pavings of a pyramidal or other shape are fixed with bitumen, asphalte, or other mastic. These pavings may be of wood, cut endwise, freestone, granite, prophyry, quartz, slag, or of different materials mixed together, affording a sufficiently resisting and durable surface.—Patent completed.

3717 N. SMITH. IMPROVEMENTS IN STOVES. Dated December 31, 1867.

In order to increase the heating power of open stoves or fireplaces, in addition to the ordinary communication with the chimney, which can when desired be closed by a register door or damper, the inventor employs two side flues or passages formed in the moulding around the fire-place or grate. This moulding is made to project forward into the room from the face of the chimney breast beyond the front plate of the stove. There are openings into these flues or passages in the cheeks of the stove, one on either side, and by and through these openings the draught from the fire enters. The flues or passages meet at the top, and the draught issues from them into the chimney, and passes by a valve which can be opened or closed at pleasure.—Patent abandoned.

10 W. J. FRASER. IMPROVEMENTS IN FURNACES OR FIREPLACES. Dated January 1, 1868.

This invention consists in the employment of rotating bars formed or provided with threads or projections arranged spirally, so that by the slow rotation of the bars upon their axes, the fuel in process of combustion is carried gradually along the furnace or fireplace. The fuel may be fed by means of hoppers, and the inventor communicates motion to the bars through suitable gearing, in connection with which a fan or fans, actuated by the draught of air, may in some cases be employed. The final specification of this patent is not at present filed, but it is probable that an extension of time will be petitioned for.

23 T. P. A. KEY. IMPROVEMENTS IN SCAFFOLDING TO BE USED FOR THE ERECTION OF HOUSES IN THE STREETS OF POPULOUS PLACES. Dated January 3, 1868.

In place of depositing building materials on the pavement, and erecting above a light scaffold of poles, ropes, and planks, the patentee places hollow wrought iron (preferably square, in horizontal section) on the footpath, and the ordinary wooden poles inside these columns. In some cases the poles (not the columns) descend into the ground, in others, to prevent slipping, he lets into the pavement stone a small stud affixed to the base of the column. The columns are connected at the top by cross girders, all but two of the girders being of the same length. The two above excepted are variable in length, and have their outer ends flush with the curb stone, forming a jetty, by which to bring the materials for building from carts, &c., to the platform thus formed by the girders when planked. Longitudinally, the iron columns may be connected by bracing of the wooden poles themselves, which will be found sufficient.—Patent completed.

3695 J. JOWETT. IMPROVEMENTS IN FIRESTOVES. Dated December 28, 1867.

This invention consists in forming that part of the roof above the firebars into an elevated hollow chamber or receptacle, with the front part sloping downwards towards the bridge, the space between the bridge and roof being contracted to smaller dimensions than usual. The effect of this arrangement will be obvious.—Patent abandoned.

Trade News.

TENDERS.

ESSEX.—For separate building for 248 female patients to the Essex County Lunatic Asylum. Mr. Henry Stock, county surveyor, architect. Quantities supplied by Mr. J. Marsland and Mr. F. G. Widdows:—

Brown	£20,400
Hammond	20,215
Hart	19,898
Adamson and Son	19,847
Perry and Co	19,595
Coleman and Son	19,358
Ashby and Sons	19,324
Wells	19,254
Browne and Robinson	19,150
Ennor	19,030
Webb and Sons	18,966
Hill, Keddell, and Waldram	18,580
Rider and Son (accepted)	18,569

DERBY.—Head-quarters and drill shed for Rifle Volunteers. Messrs. Stevens and Robinson, architects, Derby:—

Poxon, Lawley	£3334 17 0
J. W. Thompson, Derby	3040 0 0
J. and E. Wood	3000 0 0
Stoddard	2850 0 0
Desantoy	2789 0 0
R. Bridgart (accepted)	2785 0 0

EALING.—For the erection of a pair of villa residences, for Mr. Bowden. Mr. Marks, architect—

Keeble	£2179 0 0
Foxley	2160 0 0
Hyde	2085 10 0

FAVERSHAM.—For the erection of a detached residence for Mr. J. A. Anderson. Mr. B. Adkins, architect. Quantities not supplied:—

Whiting	£2180
Solitt (accepted)	2035
Shrubsole (withdrawn)	1998

HARROW.—For paving and burning for Irrigation Works, for the Local Board of Health. Mr. A. H. Jacob, engineer:—

	Per Acre.
Wright and Co.	£20 0 0
Mold	12 17
Aures	12 0 0
Reeves and Smith	9 0 0

MARYLEBONE.—For mortuary for the parish of Maryle bone. Designed by T. Gane Browning, chief surveyor:—

Jennings	£425 18 0
J. Brown	375 0 0
E. Brown	349 0 0
Crabb and Vaughan	345 0 0
Scrivener and White	334 0 0
Stevens and Watson	325 0 0
Tavener	311 0 0
Crockett	299 0 0
Turner	277 0 0
Temple and Forster	265 0

NORWOOD.—For finishing fifteen houses at Enmore Park, near Norwood Junction, for Mr. Jones. Messrs. Mathews, architects:—

Shipley and Webster	£1396
Hurley	1340
Pearse	1229

TWICKENHAM PARK.—For the erection of dwarf boundary walls and entrance-gate piers, for William Budd, Esq. Mr. F. Warburton Stent, surveyor to the estate:—

Gascoyne	£316
Hill, Keddell, and Waldram	790
David Nicholson	710

COMPETITIONS.

INDIA.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

ALDERSHOT.—September 15.—For the erection of a billiard room at the Royal Artillery barracks. Royal Engineer office, Aldershot.

METROPOLITAN BOARD OF WORKS.—September 24.—For constructing and maintaining in repair certain intended brick sewers. J. Pollard, clerk, Spring gardens.

OXFORD-ROAD, MANCHESTER.—For the erection of a new catholic church. J. A. Hansom, architect.

HIGHGATE.—September 30.—For the erection of an infirmary at Highgate. J. Moore, clerk, vestryhall, St. Pancras.

LEAVESDEN WOODSIDE (near Watford).—September 30.—For the erection of schools. J. Moore, clerk, vestry hall, St. Pancras.

WEST HAM UNION.—September 23.—For the erection of an apparatus capable of cooking for 800 inmates. F. E. Hillary, clerk to the guardians, Leytonstone.

METROPOLITAN BOARD OF WORKS.—September 29.—For the erection of fire brigade stations at Amhurst-road, Hackney, and Upper Tooting. J. Pollard, clerk to the board, Spring Gardens.

COLOGNE WATER WORKS.—September 18.—For the supply and erection of high service reservoir, two Cornish steam engines, steam boilers, likewise for cast-iron pipes, cocks, &c. At the office of the Chief Burgomaster.

MANCHESTER.—For erecting a new Catholic church, Oxford-road. T. A. Hansom, 25, Alfred-place, Thurloe square, London, S.W.

STRATFORD.—September 23.—For the erection of a store in Maryland street. H. Ough, architect, 29, Charing Cross.

PETERBOROUGH.—September 26.—For the erection of a new Baptist Chapel. J. W. Chapman, architect, 14, Great Western-terrace, Westbourne Park, London W.

EASTBOURNE (Sussex).—September 16.—For the erection of Christchurch district schools. H. E. Rumbles, architect.

PADDINGTON.—For refitting certain stoves to the new wing of St. Mary's Hospital. J. G. Wilkinson, secretary.

THORPE, NEAR NORWICH.—September 26.—For the erection of an additional wing to the Norfolk Lunatic Asylum. F. J. Blake, clerk to the visitors, Norwich.

MONKWELL-STREET, CITY.—For alterations to premises in Wind or court. Mr. W Smith, 12, Copthall court, City.

OLD-STREET, ST LUKE'S.—For new shop front to No 57. Mr. W. Smith, 12, Copthall court, City.

TAUNTON (Somerset).—September 30.—For building a shop, with house and offices. Messrs. Giles and Robinson, architects, 7, Furnival's Inn, W.C.

BUCKNELL.—September 18.—For enlarging, restoring, and reseating the parish church. T. Nicholson, architect, Hereford.

CHELMSFORD.—September 17.—For the supply of about 2,000 yards 7in. socket water pipes. A. Meggy, clerk.

HEMEL HEMPSTEAD UNION.—September 23.—For the erection of new infirmaries at the union workhouse. C. E. Grover, clerk, Hemel Hempstead.

LINCOLN.—September 23.—For the erection of the new church of St Swithin. J. Fowler, architect, Louth.

FINSBURY.—September 15.—For the supply of various articles used in omnibus building. A. G. Church, manager, London General Omnibus Company, 6, Finsbury.

BICESTER (Oxon).—September 24.—For restoring, refitting, and making certain additions, &c., to the Parish Church at Stoke Lyne, near Bicester. Rev. C. D. Marsham, the Rectory, Caversfield, near Bicester, Oxfordshire.

GLATTON (Hunts).—September 22.—For the restoration and reseating of Glatton Church, in the county of Huntingdon. James Ruddle, North street, Peterborough.

PROPERTY SALES.

AUGUST 31.

AT THE MART.—By Messrs. Jackson and Son.—Freehold water and steam mills, known as Dicker Oil Mills, situate adjoining the River Lea, Hertford, with house, offices, warehouses, &c., paddock and meadow land, comprising about 10 acres, annual value £1,000—sold for £8,600.

At the Guildhall Coffee-house.—By Mr. Whittingham.—Freehold building land, situate at Acton green, Middlesex, in 33 lots. Lots 1 to 41 comprised previous sales. Lot 44, £38; 45, £46; 46, £50; 47, £50; 48, £100; 56, £61; 57, £61; 58, £61.

SEPTEMBER 2.

At the Mart.—By Mr. Robins.—Freehold house, known as Bow Cottage, Finchley, also an enclosure of land, let at £20 per annum—£430.

Freehold residence, known as Chestnut House, adjoining above, and an enclosure of land, let at £32 per annum—£830.

By Mr. A. Savill.—Freehold house, situate at Mount Pleasant, Chigwell, let at £19 19s. per annum—£340.

SEPTEMBER 3.

At the Mart.—By Mr. W. H. Moore.—Leasehold house and stabling, No. 5, Latymer road mews, Manchester street, Notting hill, annual value £60, term 96 years from 1867, at £8 per annum—£355.

Leasehold residence, No. 62, Falkland road, Kentish Town, annual value £50, term 99 years from 1863, at £3 3s per annum—£510.

Leasehold house, No. 3, University street, Tottenham court road, annual value £60, term 98 years from 1804, at £7 10s. per annum—£595.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

Edward Myers, Camden-road, engineer, September 24, at 1—Charles Reading, Caterham, carpenter, September 28, at 12—George Webb, Old Kent road, builder, September 24, at 1—James Niemann Champion, Baring-street, Islington, house decorator, September 23, at 11—Joseph Charles Morgan, Cambridge heath-road, builder, September 16, at 12—Charles Frederick Phelps, Russell-road, Kensington, builder, September 17, at 12.

TO SURRENDER IN THE COUNTRY.

William James Arnold, Tonbridge Wells, carpenter, September 21, at 3—Ralph Porter Newcastle upon-Tyne, builder, September 19, at 10 Thomas Edward Pritchard, Colchester, plumber, September 19, at 11.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

September 23, G. Johnson, Hull, joiner and builder—September 29, W. Smith, Hereford, painter—October 14, E. Swainston, Darlington, builder—September 29, H. Midward, Old Swinford, builder—October 16, A. J. and J. H. Hobson, Birmingham, gas fitting manufacturers—October 8, J. Rathbone, Sheffield, joiner October 21, J. W. Meatyard, Mere, Wilts, carpenter—September 28, W. Nightingale, West Bromwich, plumber.

DIVIDENDS.

October 15, T. D. Kirkham, Lower Broughton, painter—September 16, H. Spink, Swineshead, Lincolnshire, builder—September 21, R. Watts, Llanllwchaiarn, Montgomeryshire, carpenter.

PARTNERSHIPS DISSOLVED.

Allen and Co., railway contractors—Price and Knight, Norwich, coal proprietors and firebrick makers—Hargrave and Parkin, Leeds, bricklayers—W. and J. Horton, Wednesbury, timber merchants—Maddock and Son, Liverpool, slaters—Glover and Co., Ranelagh road, Pimlico, gas meter manufacturers—Weatherhead and Jackson, Eccleshill, joiners.

SCOTCH SEQUESTRATIONS.

David Muir, Glasgow, contractor, September 11, at 12—Neil Young, Glasgow, brick builder, September 15, at 12.

LATEST PRICES OF MATERIALS USED IN CONSTRUCTION.

THE BUILDING NEWS.

LONDON, FRIDAY, SEPTEMBER 18, 1868.

THE NEED FOR BETTER INSTRUCTION OF THE PUBLIC IN MATTERS OF ART.

IN the report of the Society of Arts on the important subject of technical education, which has been for a considerable period under the consideration of that body, some valuable remarks upon the artistic element of such education will be found.

It will be remembered that the sub-committee appointed by the society to deliberate on the subject, and to whom the report is due, sought the aid of the Royal Institute of British Architects and of the Architectural Association at a somewhat late period, when their work was already in a considerably advanced state, and that Mr. Seddon, as honorary secretary of the Institute, and Mr. Spiers, as president of the Association, were deputed to act upon the committee as the representatives of those professional bodies. This explains how it was that the committee "reserved for separate consideration the technical education of those who are producers of works of fine or decorative art or directors of art manufactures."

This concluding portion of the report commences by saying, "it is necessary to bear in mind that for the production of works of an æsthetic character, scientific principles occupy a subordinate position, while a knowledge of the details of execution is desirable for those who design or guide the work of others. Moreover, it must be borne in mind that the taste of those to whom works of beauty appeal is far more fluctuating than the demand for productions in which utility is alone considered."

We apprehend that the taste of the public, who are here referred to, is "fluctuating" mainly because it is like the flame of an expiring candle, and that flickering would be a term more to the point. A thing of beauty is not a joy to all, simply because very few are able to appreciate it. For these reasons we heartily endorse the practical suggestion which in the report follows the above preamble, viz., "Your committee are of opinion that one of the first conditions of progress is the cultivation of artistic knowledge and taste in all classes of society."

Nothing can be more explicit than this statement, which dispels any fear as to the question of art being overlooked in the discussion, since, however late in order the subject may have been considered, its proper prominence is thus unhesitatingly acknowledged and asserted. The report continues—"With this object in view, no less than with a view to the technical education of the art workman, provision should be made for the teaching of drawing in all schools, primary and secondary, as a branch of general education, in order to train the eye and hand, and in order to cultivate habits of observation." Nothing can be clearer or more satisfactory than this. The first step towards amendment is to be aware of the fault to be amended. It is gratifying to find that, through the exertions no doubt of those gentlemen who were invited to advise with them as to the artistic questions, the committee have realised so thoroughly the importance of their bearing, and it is to be hoped that, should the efforts of the society to improve technical education meet the success which they deserve and we desire, this prominence given to them may not be lost sight of. The truths thus forcibly enunciated are by no means truisms admitted by everyone. Unfortunately the public is not only ignorant of art generally, but is equally blind to the fact and to its results. We fancy that far from feeling it to be desirable even "that drawing should be taught in all schools primary and secondary," the majority of persons would look upon such as a mere waste of time in comparison with other branches of instruction, and we think, therefore, that the committee are entitled to great credit for their discernment of the want, and that they were judicious in so tersely giving the reason for their faith.

There is an old tale, entitled "Eyes and No Eyes" which well shows the advantages to be gained by one boy over another in acquiring knowledge and pleasure during a country ramble simply by the habit of observation, and we are inclined to think that in the capacity and custom of properly using the visual organs lies most of the differences between man and man. To most persons education is necessary to train their eyes to see anything and their hands to do anything, and the cultivation of habits of observation is about the most useful culture a human being can receive. Now, that the committee should have perceived and recognised that the teaching of drawing is the best means to secure these ends is, we think, fortunate, and from the bare admission of the fact we look for useful results. As an instance of the difficulty in properly using one's eyes, Mr. Ruskin has conclusively proved that none of the earlier landscape painters—Claude, Salvator Rosa, Poussin, &c.—have drawn a single natural object as it is in nature. We are not now following him in depreciating them as poetical artists. They may, with conventional (*i.e.*, unnatural) trees, rocks, and clouds, have conveyed noble ideas, but as pretended imitators of nature they signally failed, simply for want of education of their powers of observation. And it may be safely affirmed that the host of self-constituted critics in our picture exhibitions, who one hears declaring that this and that are unnatural, have really never looked in such a manner at natural objects as to impress on their memory their actual colours or forms. What is the remedy for such a state of things? Why, to teach them to draw, that is, to put down upon paper with the hand what the eye sees, and so force the brain to observe. But it will be said that all cannot draw, a statement we would meet at the outset with a positive denial. All persons certainly cannot draw equally well, just as all persons cannot write equally well. But it is far easier to learn to draw than to write. Everyone knows the tedious hours through long years of schooling which it took them to master the intricate mystery of pothooks and hangers, for this simple reason, that pothooks and hangers, *per se*, convey no idea. Nothing enters the mind or can get fixed therein while the fingers are learning to form shapely p's and g's, but every stroke of the pencil in learning to draw *an object* is informing the mind and educating the eye.

Provided only, and it is herein expressly agreed, that the above statement is true only under a proper system of teaching to draw, for lamentably it is possible to invent a system which shall deprive the art of drawing of all its beneficial effects, and render it as an exercise less intelligent and less instructive than the formation of the aforesaid pothooks and hangers.

That such a pernicious system exists is evidently contemplated by the committee, who conclude the paragraph we have last quoted from by the observation to which we would direct especial attention. "It is essential that drawing should be part of the regular school course and not an extra lesson, and, further, *that it should be taught intelligently, not from mere copies, but from real objects* (the italics are our own). Here, again, we would give credit to the committee for the perception, though it seems obvious enough, of what is apparently anything but obvious to the world. The fact is that, though the converse of the above passage is but literal truth, and that teaching drawing not from real objects, but from mere copies, is thoroughly *unintelli ent*, it is the very system pursued in the Government Schools of Design, no less than in such other seminaries, primary and secondary alike, where drawing is taught to a few, not as part of the regular course, but as extra lessons alone.

At the present moment, we believe, there are on exhibition at South Kensington, drawings by students, under the title of "Freehand Drawing Exercises." It is obvious, at a glance, that these drawings have been made from mere copies, not from the objects themselves, and so the name of "Freehand" is a misnomer, a delusion, and a snare. They are of the pothook and hanger class—a niggling exercise of the hand, cramping the eye, and preventing the mind from thinking. The poor student who copied the acanthus leaves in perspective from a drawing some one else had made was only looking to the bent and crinkled lines on the paper. Had he done it from the plaster cast it would not have been the nice, symmetrical, and pretty, but absurd and useless, drawing for exhibition purposes, but it would have been something worthy the name of freehand, and would have taught him something about acanthus leaves, and how the curled lines in sight have reference to their fellows beyond and out of sight. His eye would have traced things, not lines; his mind would have been taking in principles, not forms. We wish clearly to be understood when we declare that the system of teaching from "mere copies" is, as the committee consider it, the reverse of intelligent, is wholly and utterly bad; it is wrong for the beginner as well as the proficient, being not only a waste of time, but absolutely pernicious. In fact, had it been invented for the purpose of preventing a person from attaining the art at all it would have had then, but in such case alone, some claim to ingenuity.

Although we have spoken strongly, and in otherwise than a complimentary sense, as to the present knowledge of and taste for art on the part of the public, we in no wise believe in any want of capacity on their part to understand and appreciate it. It has been their misfortune and not their fault, and it is due entirely to the wretched style which has overridden every effort during the past three centuries.

The public have asked bread and got but stones from the hands of their artists, and who could expect that they should take any interest in them? It has been the fashion to deny the ability of the English to produce or appreciate art of any kind. Popular prejudice has denied them even the love for music, whereas Mr. Macfarren, in an able article in the current number of the "Cornhill Magazine," shows that our nation preceded and excelled all others in its study and practice. As architects we may fairly challenge any country in the world to produce two equally national and perfect styles as our Early English and Perpendicular; and if we are sunk now in rather a slough of despond, it is in ample company, for in no branch of art need we fear to compare our condition with that of any continental nation; and the "Pestilent Renaissance" which is the cause of the blight under which we suffer was of foreign not English growth. It was a parasite which strangled the healthier insular life that struggled after better things, even to the days of Elizabeth.

SYMBOLISM.—I.

SYMBOLISM, whether in architecture or elsewhere, is essentially the representation of ideas by visible and familiar forms—as of innocence by the figure of a lamb, or of eternity by a circle. It is a kind of parable, where the more distant and important, sought to be suggested or illustrated, is presented, not in words, but in forms of things already well understood. That delight which the human mind feels in relieving the process of abstract thought, or veiling the sanctity of a spiritual object, in marrying the invisible to the visible, in letting in the light, so to speak,

through "storied windows," is at the bottom of all symbolism. But the philosophy of symbolism goes much deeper than this. It combines not only the concrete and abstract, but pre-eminently recognises the principle of fitness and resemblance. The sense of congruity must be satisfied as well as the thirst for variety and contrast. Any arbitrary visible sign, such as an +, if only agreed upon and made fixed and permanent, might serve to represent Justice as well as a blind figure holding a balance; but the greed and righteous demand of our nature for correspondence and harmony would not thereby be fully satisfied. That wonderful mode of mental manifestation which we call imagination, and which is the architect of poetry (*ποίημα*, a thing made, a work), is also the arbiter in symbolism, which is itself in a true sense poetry without the intrusion of words. Without figure or simile, what we usually call poetry is nothing but prose, or prose, perhaps, in rhyme. The construction may be very perfect, exhibiting a thing well "made," or compacted, in the grouping and action of historic events, the description of a character, or of a landscape or domestic scene; but the main element of the highest form of poetry will be absent unless the flow of thought be dimpled, oft and sweetly, by fitting simile. The invisible or abstract thing, be it spirit, principle, passion, thought, or what not, must be, for highest effect, bodied forth in tangible, material, and natural form—chastity, "like the lily"; care, "wrinkled"; and laughter, "holding both his sides." So in symbolism. Not only must the senses be presented with tangible and material forms, holding recognised relation with the thing symbolised, and standing in its stead with some advantage of simplicity and sensuousness to recommend them, but they must furnish also an element of nice and somewhat surprising correspondence, they must possess, as material things, something which is a fitting and instructive exponent of the prime attribute of the higher or deeper thing or thought they are employed to represent. Thus there must be construction, unity in variety, a bodying forth of the otherwise invisible, an adding to the wealth of the bare idea by grace and ornament; in a word, truth must be embodied and draped in all symbolism—Peace must take the form of a dove with an olive branch, Hope that of a calm expectant figure grasping an anchor.

This interweaving of threads of various hues in symbolism is not mere arbitrary prodigality and purposeless waste. It is, on the contrary, a necessity. It is the result of a craving of the mind arising from the susceptibility it has of enjoying pleasure from beautiful combinations, and of the passion it has for truth in association with beauty, and for remoter truth under the guise of what is more familiar. Symbolic representations are, doubtless, convenient oft-times as an aid to memory, or as an exciting cause of curiosity and attention, and are extremely conducive to the facilitating of mental action and perception, for they powerfully call into play the association of ideas, one of the most important facts in the phenomena of mind. But the chief charm of symbolism—the great secret of its power over mankind—is found in the stimulus and nutriment it affords to the imagination. How freely the mind soars in a region otherwise impenetrable when the sun is made a symbol of the deity, or an ocean voyage a symbol of human life.

The dangers of symbolism, both in architecture and ecclesiastical life, are at least twofold. In the former they are economical and æsthetic, in the latter they are materialising and conducive to superstition; and yet in both the danger is worth encountering for the sake of the gain. Symbolism in some of its earliest historically known forms, as in Egyptian hieroglyphics, was an economic necessity, but in modern architecture it often runs into senseless and wasteful riot. Symbolism of course is not synonymous with ornament, although decorative work is at times, and might be much more frequently made to be, symbolical. But we often see painful indications both of a want of good taste and of careless expenditure of money in this respect. The moral dangers are much more serious. Not to speak here of the readiness of the human mind, when sought to be familiarised with sacred subjects, to sink to the level of material things when those material things are made vehicles of instruction, it may be fearlessly said that the more degrading forms of superstition, where what ought to be the loftiest exercises of man's mind and soul have dwindled down into mere slavish bodily acts, are in great measure associated with symbolism. All real idolatry—a thing doubtless existing only in ignorant and depraved minds, and in all countries an abuse of this good rather than its direct product—is an accessory of symbolism. You call the various manifestations of the supernatural divinities, and for convenience sake you cast these manifestations, by force of your own imagination, into the form of beautiful or grotesque idols (*εἴδωλον*—a thing seen), that the rude worshipper may be brought into nearer contact with them, and catch some idea of them. So far so good. But by your thus throwing together (*συμβάλλω*—to throw together, compare) the visible and invisible, the spiritual and material, while it makes the unseen appreciable in the seen and tangible, it also makes it possible that, as the seen alone is then tangible to your sensuous worshipper, he, the worshipper, may by-and-bye conclude that the seen and tangible is the chief and only real object to be worshipped, and therefore distinctly associates with the idea of Deity nothing but the material form which you in your ingenious benevolence had only intended to be its suggestive and instructive representation. The origin of all real idolatry is such. Symbolism is here abused. Possibly there are Christian minds that almost to this extent abuse it in the "sign" of the cross.

BRIDGE CENTREING.—I.

WHEN the Lords of the Admiralty signified to the late Mr. Robert Stephenson their unalterable dictum, that the Britannia Bridge should have a clear minimum headway of 100ft. above high water mark, and that no fixed centreing would be permitted, the great engineer was fairly driven into a corner. Either of these conditions would have of itself been sufficiently onerous, but the imperatively demanded fulfilment of the two conjointly rendered an adherence to the recognised methods of construction an impossibility, and necessitated the adoption of means upon a scale of originality commensurate with the unparalleled magnitude of the design. The prescribed regulation respecting headway put a veto upon the employment of the arch, the type of bridge first proposing itself to the mind of the engineer. It was found that, although adopting the flattest curve consistent with safety, yet an elevation, at the springing or lowest point of the arch, of 100ft. over the Straits, would throw the crown so high that it would not be possible to reconcile the level of it with those of the adjoining railways. The question of erecting cast-iron arches with spans of dimensions so unprecedented as 350ft., without any fixed centreing underneath, was of a nature calculated to startle the most intrepid. But still this obstacle was not insurmountable; the problem was difficult, but not absolutely insoluble. The roots of the equation were real, not imaginary; the unknown quantity, recondite, but not indeterminable.

The erection of a fixed centreing, supporting the permanent arch during its construction, is plainly nothing more than employing a temporary bridge, the duty of which ceases with the commencement of that of the new structure. That the duties of a temporary bridge, constituting a series of centreings, are not of a trivial character, is amply demonstrated by the appearance of the river at Blackfriars. Under each of the iron arches at present "in position," there is a perfect forest of upright timbers, crossbraced with struts and ties, stiffened by posts and stays, and diagonally interlaced in almost every conceivable direction. A glance at these centres and the manner in which the iron arches are supported at once indicates to the practised eye the discrepancy existing between the erection of iron and that of stone arches, and in the description of centreing required. An arch of stone consists of comparatively a large number of individual parts, termed the voussoirs or arch stones, and its stability depends upon the efficiency with which each of these elemental components contributes to the equilibrium of the whole. In building a stone arch, in which the voussoirs are placed seriatim, it is evident that the support underneath must be continuous; every stone must have a bearing upon the centre, since, until the arch is keyed in, there is no self-sustaining power among its numerous components. Mathematically speaking, the *points d'appui* must be infinite. The case is otherwise with an arch similar to that of the new Blackfriars Bridge. Here the whole structure is not a collection of individual voussoirs, but composed of a number of arched ribs, which are erected in a certain number of subdivisions or sections. Each subdivision, consisting of its vertical and horizontal plates with the connecting angle irons, is riveted together before being placed "in position" upon the centreing, and may therefore be regarded in the light of one large voussoir. Supposing the length of this subdivision or voussoir to be 20ft., there is evidently no necessity for supporting it continuously. Three or four bearing points will be sufficient, their relative distances being determined by the engineer in charge of the works. The perfection of an arch would be attained when it was all in one piece. This, except in window heads and other insignificant examples, is impossible when stone is the constructive material employed, but it is virtually accomplished with the wrought-iron arched ribs used at Blackfriars. Practically, the dozen joints necessary to unite the subdivisions of each rib are equally strong with the rest of the work, and the whole may be, therefore, considered as one entire arch stone, from springing to springing. At present, the ribs at Blackfriars are completely supported by their centres, and do not exercise any pressure or thrust upon the piers or abutments upon which they will finally repose. While this arrangement is unquestionably a wise precaution upon the part of the engineer, bearing in mind how much is at stake, yet there is no doubt but that it is, viewed professionally, an unnecessary one. There is no reason why the ribs might not, similarly to an arch of stone, have been put together successively from the springing towards the crown, as the piers are amply strong enough to take any pressure that might be due to the weight, assisted by the centres underneath. In this instance we have no keying-in; the ribs and superstructure being complete, the striking of the centres will allow them to settle almost imperceptibly upon their beds of sheet lead. Looking at the different circumstances attending the construction of stone and iron arches, if we were desirous of drawing a nice distinction, we should say that stone arches were built, iron ones erected. In speaking thus critically we omit all consideration of instances where arches may be constructed of cast-iron voussoirs, and where, although the material is different, the principle is identical with that of stone. One solitary example of this type of bridge exists at Sunderland, but from the fact that it was one of the earliest specimens of iron bridges, and has never hitherto been imitated, there is little probability of it ever being taken for a model.

To return, however, to Mr. Stephenson and his difficulties, and the statement we made, that the prohibition of a fixed centreing was not an insuperable obstacle to the execution of his first idea, provided other circumstances had been favourable to the adoption of the cast-iron arch principle. It may be mentioned, *en passant*, that it is much to be regretted the arch type was not employed instead of the present horizontal form. Those who have seen the drawings of the original design must be well aware of the great superiority in an æsthetical point of view it possessed over the structure now spanning the Straits from shore to shore. There being no possibility of supporting the bridge during its erection from below, there were but two courses open—one, to endeavour to support it from above, and the other to dispense with all support whatever. Among the various plans projected for overcoming the difficulty was that of erecting the arch entire upon pontoons, floating them to the site, and allowing the burden to drop with the fall of the tide quietly into its place. Another embraced the construction of a suspension bridge, solely for the purpose of a temporary duty. But the most scientific plan was one that was borrowed from an idea of Sir Isambard Brunel, which consisted in building each arch, commencing upon opposite sides of the same pier, so that the segments as they progressed could be tied together across the breadth of the pier, and maintained in equilibrium until the completion of the whole arch effected a junction at the crown. The theory of this method of dispensing with centreing from below is perfectly sound, and might be practically carried out to a much greater extent than was at that time anticipated. The reasons we have mentioned, and others in addition, led to the abandonment of the arch type and to the adoption of that particular form of structure which at present connects the shores of Anglesey and Carnarvonshire.

RESTORATION IN THE BRITISH MUSEUM.

WE do not in these modern days see fine and high art or even common art as the Greek of antiquity saw it, or as the men of the Middle or Dark Ages saw it. We do not build Parthenons now or Westminster Abbeys, or even Temple churches, but we do build tall brick warehouses, and we do build, and nothing else, *cheap* churches. We do not carve modern saints, but we do cut out objects in stone and marble sometimes, which pass muster, and which appear to satisfy the public and artistic mind of the time and place, but which certainly are not saints either living or dead. And there is yet one other thing we do which is more remarkable still, and that is we "*restore*," as it is termed, the broken and mutilated remains and ruins of antiquity and past art; and no small amount of ingenuity is sometimes exerted to accomplish this impossible feat in the most effectual and life-killing way. Sometimes the work of many centuries, and all the results of its accumulated experience, are made to disappear in a few weeks or perhaps hours, and no small amount of fame and even glory is acquired by those who get the work to do. From the first moment when, in Westminster Abbey, the very first and primitive organ, consisting only of a few pipes and a pair of hand bellows, made its appearance, for the wonder of the simple souls who then saw and heard it, down to yesterday, when the immense modern instrument was pulled to pieces for repairs and additions, every successive generation must have puzzled itself how to improve it, and *where best to place it*. What, therefore, took a multitude of thoughtful men and centuries to do so well is in this our day undone in a single hour, and with no small amount of glory too got out of it.

If, therefore, we could for a moment hope that anything so unlikely to happen as the *real* restoration of the Westminster organ to its proper place were in time to come to pass, why all this talk will not have been in vain, and printer's time will not have been altogether wasted, and this leads me to indulge a very faint hope, that we may altogether stop, or at least hinder, another improvement which is now growing almost as fashionable and glorious as the destruction of cathedral organs—I mean, the "restoring of antiquities"—*i.e.*, antique fragments, not churches, and the then putting them under *glass* for "preservation."

Most people, I suppose, know well enough that all *white* marbles are not alike in colour. The Carrara marble is snow white when it first comes from the quarry, but afterwards, by exposure to the atmosphere, acquires a fine stone colour. The Pentelic marble, of which the Greek frieze is composed, is never white; it is always a pale stone colour from the first, and only seems to deepen a little by age and weather influences. Of course, therefore, the Museum marbles are not white, nor even pale stone colour, but have deepened a little, and are some of them a *dark* stone colour, but they are, as may be allowed, none the worse for it. Again, it must be understood that the rough quarry and natural surface of marble is, after the fine edge of the chisel has passed over it in the act of carving, gradually brought almost, if not quite, to a fine polish, and the surface thus acquires a transparency which is extremely beautiful and telling, and shows certainly the most beautiful appearance which marble can exhibit, and is that which makes it so fit for the purposes of the sculptor and carver. This is important to keep in mind. Now the Museum is a slow place, and things move in it lazily enough; the catalogues will never be finished within the lifetime of any mortal *now* living, but still there is in it a slow sort of movement which, perhaps, accomplishes sometimes more mischief than quicker changes, for nobody notices them. The Greek marbles by Phidias are now in process of *cleaning*. I ask attention to the word "cleaning," for it includes two things in modern estimation—first, the destruction of the fine chiselled surface of the marble, and then the destruction of the colour of it. Marble can only be cleaned in this sense by some very strong application, something far stronger than water or tea. I do not know what brandy or rum will accomplish, but dilute acid, or strong alkali or soap solution, will do a good deal by eating into the polished surface, and, if applied vigorously, and there is enough of it, the marble surface will disappear and the marble colour too! Let any one go and look at the Greek marbles and the busts in the Roman room, and attentively examine the colour and surface of the "cleaned," and it will soon be seen what a little energy and love of fine Greek art can accomplish in these days. It is all truly deplorable. These marbles have lasted now through evil and through good report, for some twenty-five hundred years, out of doors and exposed to all the changes of weather and neglect; and does it not seem a pity that now in these artistic and educational days, and, at least under cover, they should meet with their death sentence? Will anyone with a little influence try and stop it, and save a few of the slabs? or will anyone with a little influence or money have careful gelatine moulds and casts made of the whole series before they disappear altogether? It would really be a patriotic and truly good act, and one for which our successors will be, it is certain, not a little thankful. I speak from the bottom of my heart, for the favourite Phidian bulls have already been pretty well polished off into nothing, but are certainly whiter than they were. We are not, thank heaven! yet come to the famous and glorious group of horses on the further side of the room. I know what will be said: the damp from the badly built walls rises through the bad cheap mortar and so gets into the marble slabs. It would be a wonder if it did not. Of course it will do so again *after* all is whitened into nothingness and the surface polish gone.

But there is yet one thing more to note amongst many others, and it is a master stroke of modern ingenuity and scientific cunning. After all is done in the way of whitening the marble and destroying the surface, and all is accomplished, the next thing is to preserve it, and how is that done? It would not occur to everybody. It is done by putting the whole of the marbles in a glass case, so that it becomes almost hopeless the thought of ever seeing them more, for it is then the reflection of some skylight that is visible on the surface of the glass, and not the object underneath that is seen. This is now going on at the Museum at South Kensington. Almost everything is in a glass case: you see not the objects in them, but a reflection of yourself or a skylight or a row of gas-burners. Let us still remember that these marbles have now lasted for some thousands of years in the open air; why should they not last some thousands more under cover of a roof in a close room, and yet be left uncovered, and visible, and untouched? The sounds from the Westminster organ and the Greek marbles at the Museum are alike records and remembrances of the past, and as such should not be made mere means of a little temporary hubbub in the little narrow societies which nowadays are thought to represent Religion and Art. C. B. A.

THE INTERNATIONAL WORKING MEN'S CONGRESS.

THE third International Working Men's Congress commenced at Brussels on the 6th inst. Seventy-three delegates were accredited, twelve of them being from Paris, representing trades' unions. Mr. Young, of London, was chosen as president. Mr. R. Shaw, of London, read the annual report, which mainly consisted of an account of the various persecutions to which the International Association had been subject at the hands of continental powers. One paragraph states that in the struggle maintained by the building trades of Switzerland the masters made it a preliminary condition of coming to any terms with their workmen that the latter should forsake the association. The workmen refused to comply with this condition and by aid from France, England, Germany, &c., through the association, they have obtained 10 per cent. increase of wages, and a diminution of one hour of labour. The concluding paragraph of the report affirms that the existence of an International Association is absolutely essential to the prosperity of national organisations. The discussion commenced on the question of war, and it was suggested that working men should refuse to serve as soldiers, and to strike work while war was going on. Of what avail the refusal to serve as soldiers would be in France, or even in this country, was not stated; neither was the source of the money to support a nation of working men on strike indicated.

The second day's proceedings commenced with a discussion on strikes and courts of arbitration. The debate was preceded by the reading of papers sent in by the various local sections or branches of the association. The first paper read was from the Geneva section, and commenced by affirming that strikes are contrary to the principles of political economy, but that they are necessitated by the power assumed by capitalists of being the sole judges in all matters concerning the carrying on of business operations. It was suggested in this paper that every one of the affiliated branches of the International Association should establish a special fund for defensive purposes, and for creating a central fund like that established at Geneva. There the different societies contribute to a central fund, managed by the delegates of the different trades. With a weekly contribution of 2½d. four great strikes had been sustained. At the last strike—that of the building trades—3,000f. was placed at the disposal of the strike committee. A thorough organisation of the association in this manner would effectually prevent strikes. The second paper read was from Antwerp, and deprecated strikes both on principle and in practice. Strikes, it was contended, are destructive in every sense, and, as a means of increasing the rate of wages, are pronounced totally useless, and frequently productive of in-

jury to all concerned. The only means recognised by this paper as capable of benefiting the labouring classes and of suppressing strikes, is co-operative labour. The next paper was from the Brussels section, and expressed almost identical opinions, stating that in numbers of strikes the masters have triumphed, but in very few have the men had the best of it. In England, where the men have more practical experience in these matters, the working men assert that the reason of this is that where the men are successful in their applications for an increase of wages, or a reduction of the hours of labour, the public never hears anything about it, and that it is only when there are protracted strikes that the matter is taken notice of by outsiders, and if the conviction gained ground that the men would not strike, they would be worse treated than they now are. While condemning strikes, the authors of this paper declare that trades' unions are indispensable for keeping up the rate of wages, and an essential portion of the operations of a union should be the equable distribution of workmen. To make this completely effectual, all trades should be locally, nationally, and internationally united. A federation of trades' societies would tend to equalise wages, and would prevent work being done in one place to the detriment of the workmen in another place. Councils of arbitration, in which the workmen would be properly represented, are approved. Foremen in large establishments, it is asserted, are frequently on the look-out to lower the men's wages, in order to keep their own situations or raise their own wages. The new tendency of strikes was to the establishment of productive associations, and trades' unions will become, say the authors of the paper, the corporations of social production—*i.e.*, co-operative associations. In conclusion, the paper said:—"Strikes but perpetuate wages labour; we want to abolish wages labour. Capital is at present absorbing labour; in future labour must absorb capital. United for the defence of wages in the first instance, the trades' societies will explode the system of wages labour, and found a new social order."—In the discussion which followed the reading of these papers, a delegate from Paris stated that though the Parisians disliked strikes, they had been unable to establish councils of arbitration. To solve the question of arbitration they had proposed to elect syndics by universal suffrage—a moral power to settle trades' disputes. They had shown the Ministry that the *conseils des prud'hommes* consisted for the most part of masters and foremen, and, as a matter of course, they did not enjoy the confidence of the workmen. The Ministry had told the men that they must have confidence, and there the matter had ended. The rights of property were guaranteed by law; labour was unprotected and left to chance.—A delegate from Geneva urged that political freedom was essential for enabling the working classes of any country to remedy their grievances.—Mr. Shaw, of London, was convinced that, though much suffering had been endured on the occasion of strikes, no body of working men had ever been ruined by a strike; on the contrary, the balance of gain was considerably in favour of strikes. He instanced the calculations and results of the Amalgamated Carpenters and Joiners—a society which, perhaps, more than any other, aimed at equalisation of wages in different localities. Under existing circumstances, he was in favour of strikes as a means of enforcing the just demands of the working men, and could not agree with the wholesale condemnations that had been uttered against them.—Mr. Dupont, of London, agreed with the last speaker. The association had succeeded in many cases in preventing men being obtained from abroad to work for English employers in cases of strikes or lock-outs.

On the third day, the following resolution on strikes and courts of arbitration came on for decision. There was a very lively debate, on account of some opposition being made to certain parts, which, however, were ultimately carried, to form part of the resolution. The resolution is as follows:—

1. That strikes are not a means to the complete emancipation of the labouring classes, but that they must frequently be resorted to under the actual situation in the present struggle between labour and capital.

2. That it is necessary to submit to certain rules and regulations in their organisation, to be mindful of the proper opportunities, and not to infringe the law.

3. As there are many places in which no trades' unions exist as yet for mutual support, the International Working Men's Association ought to take the initiative to create such institutions in all trades of every country, to combine them locally into federal unions, for mutual assistance in cases of strikes or lock-outs, and by this means to organise the whole labouring population.

4. That wherever there is an opportunity and no legal obstacles interpose places ought to be named in which groups may be formed, and that in every such place the local committee ought to consist of delegates of the divers societies to constitute councils of arbitration, and to judge of the legitimacy of strikes. It will be necessary to leave the different sections a certain latitude in the mode of forming these courts of arbitration in accordance with the moral habits and the particular legislation of the respective localities.

In the evening sitting the question of machinery and its influence was discussed. The papers read dwelt principally upon the wage-reducing effect of machinery, resulting from the displacement of manual labour, and substituting women's and children's labour for that of men. That a complete transformation of society had occurred, an unprecedented progress in production made, which had resulted in a sweeping competition, which was always detrimental to the working-classes; and that this would continue as long as machinery remained the monopoly of the capitalists. The commission appointed to report upon the question proposed the following:—

Considering that the introduction of machinery in the process of manufactures has always been a means of using the labourer for the profit of the capitalist; considering that the machine will not render a real service to the working men until it is in their hands, we conclude that it is only in the co-operative association that the producers can arrive at any practical result, and that the obstacles which to day prevent working men from deriving any benefit from the machine can be removed.

In the discussion which followed, Lessner, of London, said that the Congress ought to be careful not to do anything which might go forth to spread a notion that they were hostile to machinery. Machinery had relieved man from some of his most laborious work, and it could not for ever remain in the hands of the capitalists. Although it might have been expected that machinery would have reduced the hours of labour, the contrary had been the fact; the working day had been prolonged by the introduction of machinery. Machinery, too, had facilitated the employment of women and children, and so wages had been lowered. A delegate from Paris expressed similar views, stating, however, that machinery was progressing, and could not be impeded. It enabled more human beings to live than could have lived without it, although the workmen's miseries increased as it progressed. De Paepe, a Brussels delegate, said that if the trades' unions were well organised they could claim compensation for the workmen displaced by the introduction of machinery. He proposed:—

That the machines and all the instruments of labour ought to be in the hands of the productive labourers; that notwithstanding the actual state of things, the working men organised in trade societies could attach conditions to the introduction of new machinery in workshops to receive compensation.

Eccarius (London) said it was the oppression of machinery, and not its beneficial results, which was to be deprecated. He moved that the Congress do adopt the following:—

Resolved,—That on one side machinery has proved a most powerful instrument of despotism and extortion in the hands of the capitalist class; that on the other side the development of machinery creates the material conditions necessary for the superseding of the wages system by a truly social system of production.

This resolution was received with great applause by the audience, and the Commission withdrew their proposition in favour of it. Eccarius had no particular objection to the compensation question being appended. Schöppler, of Mayence, and Cohn, of London, also spoke upon the subject. The latter expressed himself very strongly against infant labour.

The education question was discussed at the fourth sitting, and on the next day the financial statement was submitted, and papers on credit and banking and the land question were read. On the sixth day, the London delegates brought on the hours of labour question, and the following resolution was agreed to:—

A resolution having been unanimously passed by the Congress of Geneva of 1866 to the effect that the legal limitation of the working day is a preliminary condition to all ulterior social improvement of the working classes, the Congress is of opinion that the time has now arrived when practical effect should be given to that resolution, and that it has become the duty of all the branches to agitate that question practically in the different countries where the International Working Men's Association is established.

A long discussion then ensued on the peace or war question. At the evening sitting the question of private property in land was discussed. In relation to canals, highways, and telegraphs, the following resolution was proposed:—

Considering that the roads and other means of communication require a common direction, the Congress thinks they ought to remain the common property of society.

And in relation to forests the following resolution:—

Considering that the abandonment of forests to private individuals might push the destruction of forests to certain points of territory, involving the conservation of springs, and, as a matter of course, the good qualities of the soil, as well as the health and the lives of the population, the Congress thinks that the forests ought to remain the property of the nation.

The last question on the programme was, "the best means to establish co-operative production," on which subject a report was read by a commission appointed to inquire into the matter. In the evening, the Brussels section entertained the delegates at a banquet, and so ended the Congress.

BUILDING SOCIETIES.

To the Editor of the BUILDING NEWS.

SIR,—In reference to Mr. Bell's communication on "Building Societies," published in last week's issue of the BUILDING NEWS, I beg to submit that whilst in the main I agree with him, that the interest charged by these societies is, considering the small risk, much too high, and, indeed, on the average, amounting to 7½ per cent., yet in the calculations published last week he is radically wrong, and that they lead to a result far too favourable to his view of the case.

For illustration we will take his two instances, A and B. A has a capital of £100 and chooses to purchase a house value £400, rental £36, through the medium of a building society, from which he borrows £300, and to which he pays £42 annually for 10 years in redemption of loan and interest, and he is also subject to the annual contingent expenses of £10. B prefers paying an annual rental of £36, allows his capital of £100 to accumulate at 5 per cent. for 10 years, and annually invests the sum saved from the building society and in contingent expenses, and allows it to accumulate at compound interest at 5 per cent. for 10 years.

The following, then, becomes the statement of the two cases, which, in order to render the source of error more clear, is, perhaps, more complex than could be desired:—

A pays annually, for 10 years, in redemption of a loan of £300 and interest on same	£42	0	0
Contingent expenses on house ...	10	0	0
Total payments...	£52	0	0
Deduct rent	36	0	0
Total payments in excess of rent ...	£16	0	0
And loses annual interest on £100 lying dormant	5	0	0
	£21	0	0
B invests £16 annually at interest for 10 years at 5 per cent.	£202	0	0
Do. £5 per annum interest on £100 invested for 10 years	63	0	0
Capital remaining at the end of the term	100	0	0
	£365	0	0

The error in Mr. Bell's account consists in this. In his sum of £21 is already included the annual interest on £100, and it is evident that if from this £100 he yearly abstracts the interest to invest it at 5 per cent., he can only have his capital of £100 remaining at the end of the term. The interest on this sum is already accounted for in the £21. In fact, he cannot accumulate the interest on his £100 twice over.

At a first glance it may be said how can you redeem a loan of £300, and interest on same, by annual payments of the total value of £202 only? But this is altogether ignoring the payments which are made instead of rent, and which with the annual excess, equal to £42, is equal to a capitalised value of £528, and, deducting £300 from this, we have £228 remaining for interest, equal to more than 7½ per cent. on £300 for 10 years at simple interest, which is really what the building society would obtain for the use of their money, presuming that, like B, they invested each annual payment at compound interest—5 per cent. Where the interest accruing on the use of their capital is annually, quarterly, or otherwise distributed to their proprietary in the shape of dividends, this is of course impossible. In this case, their original capital only can be actively employed, and as they can invest this on more

favourable terms than 5 per cent, they are enabled to declare dividends of from 7 to 8 per cent—the rate of interest they exact from the borrower.

I have not had access to any more complete tables than those in "Hurst's Handbook," and perhaps this may account for another discrepancy between Mr. Bell's account and that I now submit. The total capitalised value of £21 invested annually at 5 per cent. for 10 years, I make £265 and not £298. This, possibly, may be accounted for by Mr. Bell assuming that the investments are made quarterly, which would undoubtedly give a higher result than mine. In conclusion, although of this I have had no actual experience, I should imagine that it would be found exceedingly difficult to invest small sums like these at 5 per cent. compound interest on safe security.

Apologising for the length to which my letter has extended, and which can only be excused by the interest which many of your readers take in this subject,—I am, &c., IGNOTUS.

SIR,—I again request your permission to offer a few remarks on the above subject, seeing that your correspondent, "Mr. Ingress Bell," adheres to his assertion "that it is really wiser to continue to pay rent to a landlord than to buy a house through the aid of a building society." In support of these views he has submitted to your readers two examples—first, that of buying a house, at the price of £400, by providing £100 and borrowing £300 from a building society; and, second, of continuing to pay £36 a year rent and investing the surplus and £100 at interest. But it appears to me he has arrived at an erroneous conclusion, and that his own calculations, if correctly made, will show absolutely no wisdom in continuing the payment of rent.

In the *first* case he takes the annual charges (*including interest on the* £100) at £57, or £21 in excess of the rent; and in the *second* case invests this £21 per annum for ten years at 5 per cent., making it accumulate to £298, and *also* the £100 capital to £162. Now both these sums are incorrect; the interest on the £21 is overstated, and the £100 cannot earn interest, as it is already included in the £21. He has thus exaggerated his profit by upwards of £90.

If I bought a house or made money investments on the conditions suggested by Mr. Bell the following would be the result of the transactions, as recorded in my ledger at the end of ten years.

First case.

HOUSE.

To cash paid down	£100
To compound interest thereon for ten years at 5 per cent.	63
To annual repayments on loan, £42; ground rent, insurance, repairs, &c., £10, making £52 Less rent 36	
£16 per annum for ten years ...	160
To interest thereon, as before	42
To cost of house, producing a nett income of £26 per annum or over 7 *per cent.*...	£365

Second case.

CAPITAL INVESTED.

£100 for ten years at 5 per cent. compound interest	£163
£16 per annum at 5 per cent. compound interest	202
By cash	£365

for investment in a house to produce a nett profit of £26 a year, as above.

If the rate of interest allowed in both cases were reduced by 1 per cent. the cash investment would only amount to £340, whilst the house would then be yielding a nett annual return of more than £7 12s. per cent., after having been debited with 4 per cent. interest on the expenditure from the commencement. It is obvious, therefore, that the house at even £400 would be a good investment.

If Mr. Bell, in reviewing the case I gave in illustration, asserts that the house referred to could not be purchased for less than £400. This is a matter of opinion. My conviction is that a prudent man would not give more than £300, and that it would be well worth buying for occupation. I would observe, however, that the value of a house depends upon the term of lease. He also says that only three-fourths of the purchase money would be lent by a society. My experience does not confirm this. In many instances the whole amount is advanced, and in others fully nine-tenths, by old-established and responsible societies.

Mr. Bell appears to base his calculations on the supposition that leasehold houses, as a rule, will not yield a nett return on the capital *sunk* in them greater than 6½ per cent. per annum. I think, however, that owners of this class of property (from practical experience) could testify to the *average annual return* being considerably more, provision being included for replacement of the purchase money. He also supposes that small sums of cash can be safely invested in realisable securities yielding 5 *per cent.* per annum compound interest, but has not pointed out where this can be done, and it is very doubtful whether he could easily do so without relying on the aid of building societies. I should certainly be glad to know where a working man could invest his savings at 5 per cent. interest with security equal to a house with himself for the tenant.—I am, &c., S. S.

London, September 15.

SIR,—A controversy has lately been carried on in your pages as to the merits of building societies, and as to the advantages to be derived by borrowers from them. As is very common in controversial discussions, the disputants, each anxious to make out a strong case, somewhat overstate the merits and defects, and the consequence is, in this instance, as in a great many others, that each party is right, and each wrong. To me, as an accountant, and entirely free from prejudice in the matter, it seems not difficult to reconcile the two, and with your kind permission I propose to offer my services as arbitrator between them, remarking at the outset that the two circumstances which determined their respective positions as to "right" and "wrong" are:—1. The number of years purchase at which the property may be bought which forms the subject of their calculations; and 2, the society from which the loan may be obtained, and consequently the rate of interest paid for it—the conclusion to be arrived at being this, that, presuming the rate of interest paid to be not more than usually extortionate, if a property can be bought at eight or ten years' purchase, it is advantageous to buy, with the assistance of a building society, rather than to pay rent as tenant, while, if the price be high, say equal to fifteen or sixteen years' purchase, then it is more economical to occupy as a tenant, accumulate the annual saving, as recommended by Mr. Bell, and make the purchase with ready cash, and on the perfectly independent terms which a buyer with the money in his own pocket can always command.

Let us assume, then, that the rent of the house is £50 per annum; that it can be purchased for £400, and that the whole price can be borrowed from a building society, repayable in quarterly instalments of £13 6s. 8d., extending over a period of ten years. The yearly payment to the society will then be £53 6s. 8d., while the other charges for ground rent, insurance, repairs, and contingencies, we will assume as being £10, making the yearly payment £63 6s. 8d., in place of £50 being paid for rent. In ten years this would come to £633 6s. 8d., while the rent for that period would have amounted to £500, leaving as excess of payment beyond what would have been payable as rent, £133 6s. 8d., in consideration of which payment of £133 6s. 8d., the party has become the owner of a house presumed to be worth £400. I have made no allowance for interest on the yearly excess of £13 6s. 8d., but even if that sum were to be accumulated at compound interest at 5 per cent. per annum, it would in ten years only amount to £167 14s. 2d., so that had the party continued to pay rent of £50 per annum, and invested the £13 6s. 8d. in the way mentioned, he would only have been the possessor of £167 14s. 2d. in cash, in place of being the owner of a house worth £400. It seems evident that in such a case as this Mr. Bell's antagonists must be held to have the best of the argument.

But if we now assume that the house cannot be bought for less than £800, the result will be different. The whole price of £800 being borrowed, as before, the quarterly payments (to continue for ten years) will be double what they were in the former case, viz, £26 13s. 4d. per quarter, or annually £106 13s. 4d., while the ground rent, insurance, repairs, and contingencies we will assume as formerly at £10, the extra cost of insurance being held as balanced by the saving of repairs from the superior character of the property, making the yearly payment £116 13s. 4d., and the ten years' payments, £1,166 13s. 4d., while the rent for the period in question would only have amounted to £500, leaving as excess of payment beyond what would have been payable as rent, £666 13s. 4d., in consideration of which the party has become the owner of a house worth £800. This seems also to tell against Mr. Bell. But had the extra payment of £66 13s. 4d. been accumulated at the rate of 5 per cent. per annum it would have amounted, at the end of the ten years, to £838 10s. 2d.; so that in this case Mr. Bell is right, and the party would be paying £838 10s. 2d. for a house assumed to have been worth only £800 at a date ten years prior to that at which he becomes the real possessor of it, the property having, in the meantime, deteriorated in value, from tear and wear, and from the shortened duration of the lease.

The rate of repayment which I have been proceeding upon is that charged by the National Freehold Building Society, calculated at the rate of 6 per cent. per annum. But that is much below the rate charged by many other societies. The only other tables I have beside me are those of a society* which, from the fact that its annual income exceeds one million, must be presumed to stand high in public favour, and I find that they are based on a rate of interest of between 7 and 8 per cent. per annum. If we assume the money to have been borrowed from it, then the result would be very much more favourable to Mr. Bell's views. It would even then be advantageous to borrow on the low class of property, rather than to rent it, but, as regards the property of superior class and higher price, it would be downright folly in anyone to avail himself of the aid offered by it, as will be made evident by the following statement.

Assuming the rent to be, as before, £50, the price £400, and the whole price to be borrowed from this latter society, then the monthly payments would be £5 9s., equal to, per annum, £65 8s; ground rent, &c., as before, £10; annual payment, £75 8s.—amounting in 10 years to £754; deduct 10 years' rent, £500; cost of house worth £400, £254. Were the yearly excess of £25 8s. to be invested at 5 per cent. interest, it would amount, at the end of 10 years, to £319 9s. 2d; but even here the borrower has benefited, having acquired a house worth £400 in place of merely possessing £319 9s. 2d. in cash.

But if we assume the price of the house to be not £400, but £800, then—the whole price being assumed as borrowed from the society—the monthly payments will be £10 13s., or annually, £127 16s.; ground rent, &c., as before, £10; annual payment, £137 16s., amounting in ten years to £1,378 Deduct ten years' rent, £500; cost of house worth £800, £878. While, were the excess of £87 16s. to be invested at 5 per cent. per annum compound interest, it would amount at the end of ten years to £1,104 7s., representing the actual cost of a house presumed to have been, ten years before, worth only £800; so that had the party, in place of accepting the aid of the building society, occupied the house as tenant, investing the annual saving of £87 16s., he would at the end of ten years have been able to expend £800 on the purchase of a house, and have had a balance of £304 7s. cash in hand.

From all this it seems evident that no general rule can be laid down as to whether it is judicious on the part of anyone to purchase through the assistance furnished by a building society or not. Each case must be determined according to its peculiar circumstances; and the advice I would beg to offer to all intending borrowers from such societies is this, that as no prudent person, not possessing more than usual skill in such matters, would think of buying a house without consulting an architect as to its value, so none should pay for it with money borrowed from a building society till he has taken the opinion of a properly qualified accountant as to whether he is or is not suffering himself to be imposed upon or misled.

Undoubted advantages derived from building society loans are, that a man is thereby enabled to have the gratification of living in a house which he can call his own, and that persons of improvident habits are thereby in a manner compelled to save what otherwise they would have squandered; but these advantages, as has been stated by Mr. Bell, are not unfrequently purchased at a very

* Birkbeck Building Society.

high pecuniary cost—of the real magnitude of which the borrowers have not the most distant conception.—I am, &c., WM. L. M'PHIN.

93, Chancery-lane, W. C., September 17.

SIR,—In a society I belong to in the city I find the secretary, besides holding this situation, is also an *auctioneer*. I am at a loss to know how it is possible for one man to do the duty of both. No wonder some of your correspondents are dissatisfied with the management of these societies. I hope there will be a good discussion on the subject in your pages.—I am, &c.,

A CITY MEMBER.

COTTAGES FOR THE CO-OPERATIVE SOCIETY, BURY, LANCASHIRE.

SIR,—We are always interested in designs you publish which have for their object the improvement of dwellings for the labouring classes, and, considering such designs open to criticism, would make a few remarks on those illustrated on August 14, for the model dwellings at Fulham. Surely, Sir, if these dwellings are considered model—built under the auspices of a bishop, and the superintendence of so noted an architect as Mr. Seddon—the condition of the dwellings upon which these are considered an improvement must be wretched indeed.

We have calculated the area of one of the middle houses, which we find contains about 350 superfeet of flooring, which is apportioned into two bedrooms containing 82 and 60 super feet respectively, with a scullery 4ft. wide, a water-closet 4ft. by 2ft. 3in., and a small living room. This is very bad, and the harm is increased by the utter disregard of all sanitary precautions in arranging the water-closet and scullery, which latter is throughout totally without light, and the former—which in houses of this description are rarely of the very best description or well attended to—are certain to prove a nuisance, and in hot seasons like the one through which we have just passed, will, we are afraid, become mere hotbeds of disease and death.

Looking down your description we find that the dwellings upon the basement floor are still worse—one bedroom and one living room, with two water-closets for six dwellings. Surely this is not model. Still more surprising is it when we come to consider the question of cost. One living room, one bedroom, miniature scullery, and water-closet, altogether containing 350ft. of flooring, and the cost £155 per dwelling! This is enormous.

We take the liberty of enclosing specimens of three classes of houses we are building in Bury for the Bury Co-operative Society, who, to their credit, are doing much to remedy the want of good cottage accommodation there, and which houses are intended to be purchased by individual members by a small increase of the rent.

The cottages No. 1 are part of a block of ten containing two large houses at each end, as shown, with six smaller ones between to suit different classes of purchasers. The larger houses contain 930 super feet of flooring, the smaller ones 725 super feet; the cost of the ten, including outbuildings, yard, walls, and architect's commission, but exclusive of land, is £1,420, or an average of £142 per house.

The cottages No. 2 are part of a block of sixteen containing each 750ft. of flooring. These houses have three bedrooms each, with garden in front and ornamental iron railing and pierpoint wall; the cost of the sixteen is £2,380, or about £149 per house. These figures speak for themselves. Our cottage No. 1, with an average of 800 super feet each, costs £142. The Fulham dwellings, containing 350ft., cost £155.

We are aware that it will be said that the expense of land in London precludes the idea of building separate cottages; this may be, but then the cost of dwellings in blocks should be proportionately reduced, as there is the saving of stairs, yard, walls, and outbuildings to each house, as well as less roof. There surely must be some wrong principle at work here. If the object of buildings of the Fulham class is merely to provide a handsome block of buildings as an ornamental adjunct to a palace, then we have not a word to say against them, but if the object is to serve as models for wholesome and airy dwellings for a large and deserving class, then let us by all means study a reasonable economy; not necessarily deforming our streets with hideous workhouse-like structures—for simplicity and taste are quite consonant—but especially aiming at providing sufficient breathing space in the bedrooms, which, in the Fulham dwellings, is sadly neglected. Were this principle universally carried out we should see fewer of our artisans with the wan, sickly faces which are a sure index of breathing foul air. We would, in conclusion, add a word to the working men themselves, and call upon them to be up and stirring; not relying upon misguided charity, not despondently wearing out their own and their children's lives and health in vile slums, where pure air is an unattainable luxury, but taking heart, by the example of their Lancashire brethren, to cheerfully and patiently work out their own redemption from these giant evils. Then, and not until then, will the English workman be lodged as a christian, and not, as is the case in most of our large towns, in dens where we should scruple to house our dogs or horses. Until that happy day arrives we must be content to see the poor carrying to the grave the results of the heritage they have received of foul air and defective sanitary arrangements from which so many of them suffer — We are, &c.,

MAXWELL AND TYKE, Architects.

2, Silver-street, Bury, Lancashire.

DESIGNS FOR THE MANCHESTER TOWNHALL.

NO one can deny that we have given a prominent place to the designs sent in for the Manchester New Townhall. We give to-day the Albert-square façade, as submitted by Mr. Thos. Worthington. On a preceding occasion (BUILDING NEWS No. 699) we gave two other views of the same building by the same architect. Having on previous occasions freely given our opinion of Mr Worthington's architecture, there is no necessity to repeat it now.

THE ARBITRATION MOVEMENT.

THIS movement makes progress. We find that at a recent meeting of the Liverpool Trade Union of Operative Bricklayers, it was unanimously resolved to request the Master Builders' Association to join them in settling a permanent code of regulations which shall be satisfactory to all parties, through a court of arbitration, as suggested by the masters in May last.

On Wednesday, a meeting of the masters and workmen in the building trade of Nottingham and district was held in the Exchange Hall for the purpose of forming a board of arbitration in connection with the trade. A resolution was carried:—"That this meeting is of opinion that it is very desirable that a board of arbitration and conciliation should be formed in connection with the building trade of this town and district." Mr. Mundella stated that there were already 500 boards of arbitration established, and there were 200 candidates for the coming parliament who had adopted it in their electioneering speeches, and who were going to the House of Commons on this principle—that working men have a perfect right to combine for their own protection; that the funds of working men ought to be protected just as effectually as the funds of life insurances or any other society which belong to the middle and upper classes.

WORCESTER CATHEDRAL RESTORATION.

THE works here are, according to a local journal, making considerable progress. The great north porch is rapidly approaching completion, all the statues being in their appointed niches, which are canopied and elaborately carved. The top or front cornice of the porch contains a row of diminutive figures, representing Adam, Noah, Moses, Aaron, David, Solomon, Jeremiah, Isaiah, and Daniel. In the centre, above the apex of the arch, is our Lord, having on his right and left the thirteen apostles, terminating at the bases on either side of the arch with St. Peter and St. Paul. These figures are by Messrs. Powell and Hardman, of Dublin. The paving of the porch floor will be of variegated stone, and the gates will be highly decorated. For these latter the skill of Messrs. Skidmore, of Coventry, has been enlisted. The outer gates will be of wrought-iron open work, richly foliated, closely copied from the best examples of ancient metal work, and in the interior of the porch, entering into the Cathedral, will be two folding doors of thick oak, with deeply sunk panels and Perpendicular tracery, canopied and buttressed, and a rich moulding of a five leaved flower, forming the outline of the arch, beyond which the Norman shafts and capitals which flank the doorway will be left remaining, as also the Decorated tracery of the window above. At the south entrance from the cloisters into the nave there will likewise be a new outer iron gate of beautiful open work, after the Early English pattern, and an inner door of close boarded work, with similar open ironwork upon it. The Chapter-house will also have a door of the same character, having around it a band of oak foliage, the niches on either side being filled with statues of a bishop and a king. The designs for these gates are prepared, and it is hoped that very shortly the general restoration (except the re-arrangement of the interior) will be finished. The carvings of the tower are being executed by Boulton, and will be completed in a few weeks. The timber truss work for the new bells will, however, yet occupy a considerable time in erection. Meanwhile, the great hour bell has been cast by Messrs. Taylor, of Loughborough, with great success. It comes out of the mould perfectly true to the intended note (B flat.) The weight is five tons, and the diameter 6ft. 4½in.

DECAY OF THE PALACE OF WESTMINSTER.

FROM time to time the public have been disquieted by the rumour that the Houses of Parliament, upon which so much money was expended, and which have been the occasion of so much art controversy, were slowly crumbling away. Experiment after experiment has been tried, only apparently to fail. Mr. Abell, the chemist of the War Department, was requested to inspect and report upon the results of the various applications, and in a paper just published he reports:—"That of the processes enumerated (each of which was applied with every care by its proposer) not one has proved successful in arresting or preventing the decay of the stone. Inasmuch as the total period which has elapsed since the application of these processes is less than four years, it would be superfluous to discuss their relative merits or demerits. I may, however, observe that one half that period of time had sufficed to demonstrate the utter inefficiency, as applied to dolomites, of the majority of the processes, and that the only one which until comparatively recently afforded promise of success was that proposed by Mr. John Spiller." Mr. Abell then enters into an examination of several systems. He gives preference to the process of Mr. Szerelmey, but this one is very defective. From his concluding paragraph we are led to hope that something may be done, however. "In my recent examination (he remarks) of the stone of the Houses of Parliament, both in the original and prepared condition, I have been strongly confirmed in the conclusion to which I arrived when my attention was first directed to this subject, and which was also entertained by the committee appointed in 1861, of which I was a member; namely, that the principal cause of decay of the stone is the lodgment of water, and its frequent retention for long periods by the exposed portions, and especially by those parts which are situated immediately between string-courses and other projecting surfaces. I am convinced that if the recommendation of the above-named committee had been acted upon, and such projecting surfaces had been protected, either with a light metallic covering, or with some other sufficiently impervious coating, the most disfiguring portions of the decay, which has been proceeding since 1861, would have been arrested or prevented."

The western extension of the Metropolitan Railway is now virtually completed. The laying of a few lengths of permanent way and the carrying out of some minor details at the stations will render the line ready for traffic. The official inspection was made on Monday last, and the line will be opened for traffic on October 1. This portion of the Metropolitan Railway system leaves the parent line at Praed-street, midway between Edgware-road and Bishop's-road stations, and joins the Metropolitan District line at Gloucester-road, Brompton.

MR THOS WORTHINGTON, ARCHT

SUBURBAN *VERSUS* URBAN BURIAL.

THIS important question, which during the past eighteen years has, by a sort of common consent, been allowed to rest *sub silentio*, and, in the vast enlargement of London, find a new level and fresh exigencies, must, we presume, in the new parliament, in some form or other, come up for discussion. Except, perhaps, in a solitary column of the Registrar-General's annual report, or in some semi-philanthropic paper read before one of the learned societies, the fact is rarely noted, that death carries off from the London population something near 70,000 persons every year; a number equal to the population of a large-sized provincial town. For example, the annual mortality of London is considerably more than the whole population of York, Hull, or Durham. Hence, it may well seem a consideration of some moment how and where this large number of human bodies are disposed of in burial? As a matter of fact, some 50,000 or 60,000 of this number are buried within the limits of the metropolis, notwithstanding the prohibition of such interments, by the act of 1850. The London suburban districts of 1850 are the urban districts of 1868. The principal metropolitan cemeteries, with the exception of the Necropolis at Woking, are all within the postal districts, and some of them now in the very midst of large and rapidly increasing neighbourhoods. The question may, therefore, fairly be raised, whether burial in those neighbourhoods is not in direct contravention of the spirit of the act of 1850. On sanitary grounds the matter is beyond controversy. Many of the cemeteries which, in 1850, were condemned by the then existing Board of Health as unfit for further use, are now as choke-full of human remains as were the common graveyards of that period, and cannot be disturbed without loading the air with poisonous miasma and incipient disease. In this special view the subject is most dismal and uninviting. But it will have to be approached and dealt with vigorously and thoroughly; though, perhaps, not till some sweeping epidemic has again taught us in its painfully imperious way the folly and wickedness of neglecting, in our municipal regulations, sound sanitary laws.

NOTES FROM SALISBURY.

(FROM A CORRESPONDENT.)

A TRIP to the episcopal city of New Sarum has plenty of archæological interest to recommend it, but little or nothing of the present. A fixed population, pleasant, homely, and sociable, with the surroundings of antiquity, its elegant spired cathedral rising out of a plateau of rich pasturage and water meadows, over which, at eventide, a thick mist may be seen hanging like a cloud—Salisbury, in a word, has all the circumstances of a quiet sequestered city, though sadly deficient in modern improvement. Though very flat, few cities are so badly built as regards regularity of style. Its streets, composed of tiled and gabled houses, present a picturesque mixture, or, as we moderns would say, a jumble of private houses and shops. There is, moreover, a strange admixture of cleanliness and squalor, and an absence of enrvature in the streets that, combined with their flatness, divests them of the picturesqueness noticeable in other cathedral cities. This is, perhaps, partly attributable to the streets being laid out rectangularly, or intersecting each other at right angles. So much for the general aspect. We would urge the necessity of filling-up the water-courses or open brooks that now drain the streets, and substituting an efficient system of sewerage, as such open courses must be detrimental to health by polluting the atmosphere with the sedimentary deposit, and adding to an already humid air. We believe the authorities are doing something in this direction.

Besides the Cathedral, there is little of much architectural interest, though there is plenty of detail of the fourteenth and fifteenth century work to repay sketching here and there. The Poultry Market Cross, hexagonal on plan, is a not very pure example of Late Decorated of Edward III.'s age. The Council House is as heavy and ugly as any of the pseudo-Classic erections of the Georgian era, and in this category may be classed the Infirmary.

The glory of Salisbury, its cathedral, always repays a visit. Externally, we noticed that considerable progress had been made with the western front restoration under Mr. Scott. The niches are being fast re-tenanted, and the sculptor is doing his best to preserve the original character and feeling of their saintly occupants, comprising in all upwards of one hundred statues of apostles, saints, and prelates. New Plymouth marble shafts have replaced the old ones, and we think the capitals to those of the western porches should be thoroughly restored rather than only partially renewing them by leaving some in their former perishable and almost indistinguishable state. Such restoration is to our minds over-conservative. As to the western façade, as a whole it is but a frontispiece—in modern parlance a sham; and had it been erected nowadays would have been deemed intolerable. As our readers probably know, it totally conceals the aisles, and is coped level with the springing of nave roof. The detail of it does much, however, to atone for this defect.

The plinth members, a few years ago in a great measure hidden by the ground, have been brought to light, and a well-paved border, forming a fitting basement, has been laid, with an ample fall outwards to a channel gutter. The noble tower and lofty spire have been thoroughly repaired, as likewise the whole external fabric, and here and there pinnacles and weatherings in new white stone contrast rather markedly with the rich grey brown of the old stonework. Perhaps the finest view of this purest of our mediæval cathedrals is at the north-east entrance of the close, the grouping of the double transept (the plan being that of a double or archiepiscopal cross), and the grand centralising feature—

> The lessening shaft of that aerial spire,

being all that the artist of skyline could possibly demand.

The restoration of the Chapter-house, under the superintendence of Mr. Clutton, is now complete, the central shaft of Purbeck marble restored to its perpendicular, and the whole interior has been most harmoniously treated polychromatically, the original colouring being preserved as nearly as possible. The colours are chastely subdued, no bright or pure colours obtruding. We will resume our notes on another occasion.

HOFFMAN AND LICHT'S METHOD OF BRICKMAKING.

THAT brickmaking is a very ancient business needs hardly to be said. Moreover, the quality of the bricks produced seems to have been deemed an important consideration at an early period, for did not the builders of the Tower of Babel say to each other, "Let us make bricks, and burn them thoroughly?" Thus, although the Egyptian bricks at which the Israelites toiled had apparently been merely baked with straw to give them tenacity, the builders of the earliest times must have made bricks in substantially the same way as they are now made.

A very excellent and scientifically complete mode of brickmaking has just been established (says the *Aberdeen Free Press*) at Ruthrieston, by Messrs. Keith, Harrimann, and Watson, of the Northern Patent Brickworks. The new works are constructed on the principles of Hoffman and Licht's patent annular ovens, only that the kiln—if it may be so called—in place of being built in the form of a circle, has been built in the form of an oval. Let the reader, then, imagine an oval 175ft. in length and about 95ft. wide, as the extreme width. The circumference is formed of something like a small railway tunnel, arched with firebrick, and strongly bottomed with the same. There runs round the whole oval the tunnel, as we have called it, being a chamber about 15ft. wide and 8ft. to 9ft. in height; the outer walls, 10ft. thick at the base, and in which are twelve openings or doors, dividing the whole into as many sectional chambers. Inside the tunnel is another brick wall, or rather double wall, filled with earth in the middle, with smoke chambers, and a number of flues pointing towards the centre of the oval, from which rises the chimney stalk, 175ft. high. In the tunnel we have described the bricks are burnt. As we have said, the tunnel is divided into twelve chambers. Each of these is capable of containing 15,000 bricks, representing a day's produce of the ovens. The *modus operandi* is this:—In place of only one apartment or chamber being filled at a time the whole are filled, save one, which is being emptied of the burnt bricks, and another next to it, which is being simultaneously filled with "green" bricks, the fire being meanwhile kept up in only one chamber. But it is here that the special value of the patent oven is seen, for while the fire is led round from one chamber to another, feeding coal through a series of small metal-covered holes in the crown of the arch (the whole of the chambers being hermetically closed up to the one that is being emptied, which is shut off at the end nearest the fire by an iron door), the hot air and flame, finding no other means of escape, go forward into the chambers in advance of the fire, gradually heating up the wet bricks. Nor is this all, because the cold air that comes in where bricks are being emptied must pass through a series of chambers in which the bricks burnt on four or five days preceding are cooling. It touches, first, a chamber of nearly cooled bricks; next, one burnt a day later, which is considerably hotter; then another, hotter still, till by the time it reaches the fire it is quite at the point of combustion, carrying forward the flame in waving lines among the interstices of the burnt bricks. There is thus secured the utmost possible economy of heat, and at the same time any smoke evolved is thoroughly consumed, the only "visible emanation" from the top of the chimney stalk being a little steam off the green bricks when they begin to feel the influence of the heat. The economy in fuel which is secured by these means is of course obvious, while the scientific principles on which the power of the fire is concentrated enable the cheapest coal dross to be used in firing. All these arrangements will materially cheapen the price of bricks.

CORNISH CHURCHES.

IN a paper sent to the "Archæological Journal," in 1854, by Mr. J. J Rogers, of Penrose, it was stated that in Mawgan Grade, Cury, and Landewednack parish churches were low side windows called lynchnoscopes, "at the south-east angle of junction of transept with chancel." At Wendron Church, says a correspondent of a Cornish paper, was one in the north wall of the chancel, and somewhat removed from the angle of the transept. Mr. Rogers deemed the date of these lynchnoscopes to have been shortly before the Reformation, and that it was difficult to determine their utility with certainty. It appears that the east chancel windows of Mawgan and Wendron churches are similar, and that they date from the middle of the fourteenth century. At St. Helen's, Hangleton, in Sussex, wrote Mr. Rogers, is a south low window, like that in St. Wendron Church, 5ft. by 13in.; that at Wendron is 3ft. 9in. by 11in. Probably all were contemporaneous, and not part of the original plan of the church. A writer in the eighteenth volume of the "Archæological Journal" deemed it to be probable "that the characteristic features of Cornish and Devonian churches—the absence of any constructional distinction between nave and chancel—is traceable to the primitive arrangement of the old Cornubian oratory, that of a double square without break. Even the church of St. Gwithian is not really an exception to the general rule. Padstow Church was rebuilt in the fourteenth century, but some parts may be traced to an earlier period. The font and piscina are engraved in "Lyson's Cornwall," and show respectively the

twelve apostles and the patron saint. In the "Gentleman's Magazine," 1781, p.305, it was stated that the north aisle of Cornish churches was not used generally. A field, generally glebe land, was near the church or cemetery, called the "sentry," as that near Canterbury Cathedral, being Cemetery Gate, is called "Sentry Gate." As to cemeteries, Mr. W. Cotton, in his "Illustrations of Stone Circles and the other Remains of the Aboriginal Britons in West Cornwall," 1826, stated that in Cornwall and elsewhere, are kist-vaens, an enclosed area, the size of a human body set up in the ground, which enclosed dead bones. The cromlech is a kistvaen of larger side stones, covered with a mass of magnitude on the top, as the cromlechs of Molfra and Chun. Mr. Cotton referred to the fourteenth volume of "Archæologia," where the Lanyon cromlech was described "with human bones," which left no doubt of its having been on an ancient sepulchre. In the "Encyclopædia of Antiquities," vol. II., page 508, the kistvaen is stated to be "for the reception of corpses." When covered with earth or stones it was a cairn. When the destructive fire occurred at St. Hilary's Church, near Penzance, the tower was preserved, where in 1853 a Roman stone was discovered. It was built into the wall, and was inscribed to the Emperor Constans (A.D. 337-350), or to Constantius II., his successor.

NEW DRAINAGE AND WATER WORKS AT BEDFORD.

ON Friday, the 11th inst., these works were officially inspected. The water is obtained from an artesian well, which is driven through a bed of very close-grained, compact limestone. On the excavation attaining a depth of 25ft., several large fissures in the rock were met with, from which strong jets of water bubbled up, and from that moment the supply has continued at the rate of 200,000 gallons in the twenty-four hours. The storage well is 60ft. long, 18ft. wide, and 25ft. deep; with this is connected a pumping well by a heading 60ft long and 6ft. wide. For raising the water there is erected a perpendicular plunger, worked by an engine of 40-horse power. This engine will pump 30,000 gallons per hour. The perpendicular lift of the water from the well to the reservoir on Foster's Hill is 150ft. The reservoir is cut out of the dense boulder clay which forms the eastern ridge of the Ouse Valley, and as the top water in it stands 140ft. above the average level of the town of Bedford there is pressure sufficient to throw a jet to the top of the highest building. The tank is 64ft. long and 60ft. wide, and contains 15ft. 6in. of water, giving an available supply (in round numbers) of 400,000 gallons of water, double the quantity at present required for a day's consumption. The reservoir is covered by a roof, supported on iron columns. Near the reservoir, on Foster's Hill, is the highest portion of the system of sewerage, and the contiguity of the waterworks is a great advantage, as the whole system of drains throughout the town can be completely flushed at any moment with the greatest ease. Bedford, from the peculiarity of its situation, has been more than once described as a town not capable of being entirely drained, but Mr. Lawson, the engineer, made the most minute surveys, and his drawings sent in to the Local Board included sections of every street and site likely to be brought into connection with the sewerage operations at any future time. There are thirteen miles of main sewers, all straight, and capable of being seen through from the manholes when inspection is needed. There are two levels in the system, but they come to one outfall, provision being made in the upper level for conveying sudden overflows of storm water into the river. The main sewer on the north side is brought to the left bank of the river, and passes along the margin, the surface being utilised as an embanked promenade, 25ft. wide. In the suburb of Waterloo the main sewer of the south side of the town is brought under the river by a tube, joining the main under the embankment, which is continued by the side of the river for three-quarters of a mile, until Newnham is reached. Here, a tank has been constructed for the reception of the sewage. From this tank it is lifted by centrifugal pumps, worked by 12-horse engines to the "lift," whence it passes by gravitation to a field of 54 acres, where it is distributed. Mr. John Lawson, C.E., was the engineer, Mr. J. Lund the clerk of works, and Mr. L. B. Moore the contractor.

ART SCHOOLS IN PARIS.

IN the year 1851 the following establishments for instruction in drawing and the decorative arts existed in Paris:—The Impèrial Mathematical and Drawing School (Ecole Impèriale de Dessin et de Mathématiques); the Free School of Design for Young Girls; five schools aided by the city of Paris, of which two were female schools; and seventeen courses of instruction in drawing attached to the adult classes. At this date the sum set apart annually by the municipality of Paris for art education only amounted to 39,000f.

Since the year 1851, both the number of schools and the grants in aid have very largely increased. This increase is, in great part, due to the reports of the French jurors at the Exhibition of 1862, who were loud in praising the great advance made by England in design and decoration since the development of her art schools, and who did not hesitate to express an opinion that much must be done in France to enable her to keep her place in the front rank of industrial art. An establishment for advanced instruction in art for men is now in course of being formed.

It is proposed:—

1. To create a museum and library of applied art, consisting of objects presented or lent for a certain period; the collection to be continually augmented by specimens, models, or photographs of all the art-products manufactured in France.

2. To found a superior and central normal school of industrial art.

3. To organise special exhibitions of designs and works of art, with competitive prizes.

A portion of this programme has already been carried into execution by the Central Society of Applied Art (Union Centrale des Beaux Arts Appliqués). This society is already favourably known by its periodical exhibitions at the Palais de l'Industrie, and of works of art of different epochs. The last of these exhibitions was enriched by many objects lent by celebrated collectors, and was very numerously attended. The project of a museum and library, to be opened in a room in the Place Royale, is still in embryo; but the normal school is in course of being organised, and, by special permission of the Minister of Public Instruction, it is to have the title of college—"Collège des Beaux-Arts Appliqués à l'Industrie."

ST. PANCRAS WATER SUPPLY.

THE oldest waterworks in the metropolis, says the *Marylebone Mercury*, are said to be those connected with the Highgate Ponds, which supplied the City of London before the New River was formed, and which were in the possession of the Hampstead Waterworks Company until a few years ago, when that company was bought up by the great New River Company. The water from these ponds is still supplied for non-domestic purposes to the districts extending as far as King's Cross, and during the present season numerous complaints have been made to the vestry of the stinking water thrown on the public roads. Dr. Hillier, Medical Officer of Health, has also reported to the vestry as to these ponds, representing that they received a certain amount of house drainage, and that there is an iron pipe entering one of the upper ponds which brings foul water, and apparently house drainage. The drainage of the upper part of Kentish Town, both east and west of Kentish Town-road, is certainly very unsatisfactory, and urgently requires the serious attention of the vestry. Mr. Rouch, the Sanitary Inspector, has also reported that he found a flow of sewage water into pond No. 4, from an iron pipe laid into the pond from Fitzroy Park Dairy, and an accumulation of black filth where the down pipe discharged into the pond. On representations being made to the New River Company as to the state of the ponds, a letter was received from the secretary, stating that "the New River Company have received a serious complaint of the foul state of one of the Highgate ponds, near Milford-lane. Our engineer, on several occasions, has represented to your surveyor the necessity of action to abate this nuisance, who intimated that a committee of his vestry had inspected the affected locality with a view to apply some remedy, still nothing has yet been done. I am, therefore, desired strongly to urge the necessity for your constructing drains to intercept the sewage, which has now become intolerable to the neighbourhood, and prejudicially affects the quality of water used by the company for ordinary non-domestic purposes." The vestry, having referred the matter to the Committee of Works, that committee, accompanied by Mr. Scott, the chief surveyor, has made a careful inspection of the locality, and it has been clearly ascertained that sewage has been brought into the pond in considerable quantities. The matter is now under further consideration by the Works Department. The New River Company state that the water from these ponds is used for "ordinary non-domestic purposes," but the officers of the vestry have proof that either filtered water or this impure water can be turned on at the pleasure of the company.

VILLAGE WATER SUPPLY.

IF anything were needed to impress more deeply on the public mind the necessity of a plentiful supply of water and the hardship consequent on its scarcity the protracted drought of the last summer must have had the due effect—at any rate upon the minds of country residents. In large cities the evil has not been so much felt, although many of the provincial towns—Liverpool and Sheffield to wit—have been obliged to diminish their accustomed supplies in order to prevent total exhaustion. In country districts the condition of things has been bad indeed. From day to day we read in the daily journals of many weary miles over which farm stock had to be driven to obtain water; and in many villages the inhabitants were paying for the precious fluid at the rate of ½d. and 1d. per pail. To remedy this Mr. J. Bailey Denton makes this week, in the *Daily News*, several valuable suggestions applicable to different districts. He first proposes to render it compulsory on all owners of cottages in villages to provide, by the construction of tanks, as much soft water as the roofs will furnish. By the Sanitary Act of last session all owners of cottages are obliged to supply privies and ashpits properly secured, and there is no reason why this compulsory provision should not be extended to water tanks. For purposes of drinking a different supply is necessary, and in seasons of drought, like that which has just passed, the tanks of course will fail. To meet this state of things, it must be made compulsory on the vestry or sewer authority to have in reserve a sufficient supply. The practical effect of these compulsory provisions will be to secure, in many instances, one copious and constant supply for all purposes through the sole agency of the sewer authority, as the cheaper and better source.

The storage of roof-water by underground tanks will in some years provide all the soft water required, and in many districts throughout the old and new red sandstone, the Bagshot sand and the postertiary drifts, a shallow well and ordinary pump, costing between £15 and £20, will often serve a whole village under all circumstances. Where such a shallow well will suffice, Norton's Abyssinian pumps may frequently be adopted. They will cost less money, and where a village is straggling, or of any great extent, they may be multiplied with great advantage. In other cases, where constantly running streams are not far distant, they may be turned to use by the application of the motive power they afford to raise water to tanks on higher ground; or the surplus flow of those streams in winter may be collected and dammed up for summer use.

But these facilities of obtaining water do not extend over the whole country. On the contrary, about one-third of the rural population must resort to the storage of the winter's excess of rainfall if they are to have a constant supply through the summer. This is the case with a large proportion of the flat lands of Lincolnshire, Huntingdonshire, and Cambridgeshire, as well as those that exist on the east of Lancashire, and in Somersetshire, Kent, and Essex, and of those high grounds which distinguish the porous chalks and oolites, and the clays overlying them. The "fog ponds" of Wiltshire afford us a lesson of how wonderfully nature will assist art where man does his best to help himself, and to provide for the animals dependent upon him. Some of these ponds existing on the tops of the chalk hills are known not to have failed throughout the whole of the dry summer just passed, although they have served with water many hundred sheep during the whole period of drought.

We know how little the rain has helped to maintain the supply of these ponds, and that they must, therefore, have been replenished insensibly and wholly by the hygrometric condi-

tion of the atmosphere. On the porous chalk and oolites the use of "fog ponds" may readily be extended to the supply of villages as well as cattle and sheep. We have only to study more closely than we have hitherto done the data Nature has afforded. In clay districts, recourse must be had to the storage during winter of either the surface rain water or the discharge of under drainage. The minimum quantity obtainable from the latter source will be at least 2½in., or 60,000 gallons per acre, for every acre made tributary to the supply. If, therefore, we seek to supply a village of 100 dwellings and 500 inhabitants, and assume that it is necessary that each person should have ten gallons of water per diem for 120 days, and that an allowance of 50 per cent. must be made for waste by evaporation or otherwise, it will be necessary to store 900,000 gallons to satisfy the case. Thus the minimum drainage discharge of fifteen acres will suffice; and a reservoir of half an acre in extent, 7½ft. deep, will hold the requisite quantity.

The cost under ordinary circumstances, including delivery by stand pipes, for public use in the village, would vary from 3d. to 1s. per person per annum, where the cost is reduced to an annual charge on the properties forming the village, assuming that the money to pay for it is borrowed by the sewer authorities, and repaid by instalments in thirty years at 6 per cent. In considering that each inhabitant requires ten gallons a day during the summer, Mr. Bailey Denton considers he has taken an extravagant quantity. It will be advisable, nevertheless, to provide a superabundance, in the hope that with increasing intelligence, and under the influence of sanitary examples, the use of water in villages will be largely increased.

RELIGIOUS ART IN THE NINETEENTH CENTURY.

WHY should religious painting be now extinct throughout Europe, is a question often asked, and the reasons given in reply are more numerous than satisfactory. The vital spirit being fled, the body of art, it is said, lies dead. On the other hand, we are met by two facts—first, that the world is still able to produce much good art; and secondly, that religious communities both in England and abroad give many practical proofs of the possession of true religion. The misfortune would seem to be that the good art and the true religion cannot be brought together. Thus "religious art" seems to be in abeyance partly because religious people deem themselves too good to care about art, and partly because painters are too exclusively artistic to give much heed to religion.

What the world wants, said Dr. Arnold, is not so much positive religious writings as secular works animated by a religious spirit. And this perhaps, after all, is the want in art. The problem between the Church and the world, which many earnest minds are seeking to solve—how to make religion practical and the world godly—may possibly involve the causes and the remedies for that breakdown in art which certainly is an unhappy anomaly in the existing phase of our civilization. Religious art is now severed from the world's life, and it seems vain to look for revival save through a recurrence once more to what is actual and real. Painters of old were able to take a man from the streets and put him upon canvas as a prophet. Thus Raffaelle, seeing a simple mother and child seated in the public way, seized the top of a cask as nearest to hand, and sketched on the very spot the circular composition now know in the Pitti Gallery as "La Madonna della Sedia." So with our artists; if, instead of vainly striving to emulate Fra Angelico, they would paint religion as she walks through the world, and mark the visible signs of duty and devotion in daily life, works might be produced which should come home to the experience of the people. This line of reasoning makes Overbeck, with the entire school of so-called Christian art in Germany, a warning rather than an example. Such modern revivals stand as anachronisms in the nineteenth century—pale shadows and false shows. Nothing, indeed, can be more certain than that, in all vital creations in sacred art, no abrupt transition is found from secular to sacred, no impassable barrier raised between the world and the Church. As to architecture, we know that the people passed at once from pointed doors in the houses where they dwelt to pointed porches and vaulted roofs in the churches where they worshipped; no invidious distinction was made between the mart for merchandise and the church for prayer. In fact, in all countries, and under all creeds, the law under which an earnest and true art has been developed appears to have been similar. Thus, in Egypt we find no essential difference between the palaces, the temples, and the tombs; the same art, in architecture, sculpture, and painting, encircled the people at their feasts, their festivals, and their funerals. So it was in Assyria and Greece. Religious art drew vitality from the life of the people; noblest form and action in grove or temple was modelled in the clay, and the people who walked the streets of Athens found, through sculpture, apotheosis on the pediments of the Parthenon. Even hostile religions may come into accord through art. St. Paul, while standing on Mars Hill, could see the figures of Phidias as they looked down from the Acropolis; and now these marbles from Minerva's Temple, and the cartoon of the Apostle preaching to the people of Athens, brought almost side by side in the same metropolis, seem to show that art, when noble and true, is almost of necessity religious. A spirit solemn and silent presides over the Elgin Marbles, and many minds will feel that the Theseus of Phidias has at least equal religion with Thorwaldsen's figure of Christ. The platitude then may be once more permitted, that the condition for the birth of every religious school, whether classic, mediæval, or modern, seems always the same; the religion and the art must hold together closely, must be knit compactly as in unity of organic life, and, above all, must not be bound down to obsolete tradition and vague abstraction.

Yet it were rash to assert that religious art, worthy of the name, can in any age of the world be readily obtained; otherwise Europe would scarcely have remained without it for the last three centuries. We would say, indeed, even at the risk of paradox, that one difficulty, especially of late, has been that the proximity between art and nature on which we have insisted has been made even too close. In fact, to gain proximity to actual life and yet to preserve distance, to stand on the common level and yet to rise to an elevation, involve some of the chief difficulties in the settlement of a sound religious style. The German modern school and the English school, if we have one, err in fact in opposite directions; if the one may be designated sublimated spirit, the other assuredly is too substantial flesh. Such pictures, for example, as Mr. Holman Hunt's "Christ and the Doctors," and Mr. Madox Brown's "Patriarch Jacob," however admirable otherwise, are too near to common nature. The "Doctors" in the Temple, though picked up, we believe, in modern Jerusalem, might equally well have been taken from some of the Twelve Tribes that dwell in the Minories. In aspect they have not the calling of prophecy, but only the trade of old clothes. It must be admitted that some of our would-be religious painters treat nature with a familiarity which breeds contempt. Coleridge said that a picture ought to rise to an intermediate something between a thought and a thing. Mr. Herbert's "Moses" in the Houses of Parliament, and certain of the Legislators painted by Mr. Watts in Lincoln's Inn, may attain to the desired abstraction without loss of the required individuality and reality. The old painters, at any rate, had a faculty for drawing near to nature, while rising above her. Saints portrayed by the old masters are men, and something more; prophets and apostles standing in Italian pictures bear not the aspect of mere ordinary men or every-day acquaintances with whom we may shake hands and chat; they inspire awe rather than invite to familiarity, for they seem to have held converse with the skies. Yet it becomes a question worth the inquiry of those who may seek a style consonant with religion, how far this elevation of spirit which has been termed supernatural is beyond or contrary to nature. The better opinion would seem to be that the so-called supernatural or spiritual principle in art is but a higher aspect of nature, that the storehouse of creation contains materials more than sufficient for the artist, however transcendental may be his aim. Thus it would appear that the office of the painter is chiefly to select. Still something more nearly approaching to a mental function is needed than the "pre-Raffaelite" operation of penny-a-lining. What is mainly required is such study as shall lead to the clear understanding of nature's meaning, to the distinction between essentials and accidentals, to the discrimination of the difference between generic forms and individual detail. The subject is far too large to admit of elucidation within small compass. It may, however, be added that in these studies help may be found in Oersted's Essays, which treat of the philosophy of nature; also in German authors who descant and dream on æsthetics; likewise in the discourses of Reynolds under the head of general ideas. The practical lesson to be learnt from such inquiries seems to be that the religious painter of the present day must do something more than copy the individual model before him. In London we knew a model who was accustomed to personate the Apostles, and we have encountered in the streets of a provincial town an old man who, following the calling of a common porter during the day, sat by night before the students of the Academy as St. Peter. And what was the result? Why, of course, the studies made were after all nothing better than the realistic figures painted by that Neapolitan school of Naturalisti who mistook lazzaroni for Apostles. The English porter looked upon canvas the porter still, notwithstanding a beard worthy of St. Peter.

The preceding thoughts may be put into another form; thus it may be said that nature, before she takes her place in a religious composition, requires what artists in general call "treatment," and what Reynolds signified by "style"—that is, a style and treatment in keeping with the subject-matter. We have seen how Phidias, a pagan, rose to religious expression; and, under a very different guise, Gothic carvers in our venerable cathedrals fashioned a true Christian art; they reached, through stiffness, solemnity; through restraint, a repose and dignity not far from religious. As usual, our modern revivalists seize defiantly on defects, and thus certain manifestations of religious art in the present day—for instance, painted windows and carved doorways to modern Gothic churches—though commendable in motive, are hard as petrifactions, and lifeless as fossils of extinct species. The treatment which nature calls for at the hands of art may find illustration through literature, whether sacred or profane. In the transition, for instance, from prose to poetry, nature has to be thrown into artistic form; she has to be dressed for the occasion; the thoughts must be cast into rhythm and symmetry, and the stanza, when settled, encloses, as it were, the imago within a frame. More express illustration may be found in the sphere of religious poetry, and especially in the poetic parts of the Bible. It is not easy to define, either here or in sacred art, wherein consists the religious style or treatment. Sometimes it may lie in a stately roll of periods, sometimes also in a certain severity of manner, generally in simplicity, often in repose, and certainly usually in humility rather than in ostentation. Most easy, however, is it to tell, either in a written or a painted composition, when all goes right, and it is equally soon felt when anything is wrong; for even an inapt word or metaphor, or an ill-placed line, may at once break the spell, and sink what might otherwise be sublime into the ridiculous. The Psalms, Isaiah, the Book of Job, afford illustration, at least indirectly, of the treatment which religious art calls for. Even the translators of our Bible were religious artists in the best sense of the word; no such artists are now found to work on paper or on canvas.

We have already said that one reason why religious art in the nineteenth century has been a failure is that it does not belong to the century; that is, it ceases to reflect the Christianity by which men now live and die. It must be admitted, indeed, that some of the older phases of our faith were more pictorial than the present forms. There was a breadth, simplicity, picturesqueness, and, as it were, a colour of emotion, in early popular belief, which is now wanting. When teachers spake in parables, church walls were covered with sacred panoramas, for an artist can paint a parable, but not a creed. Still, means of revival might possibly be found if, for example, as already indicated, art could assume somewhat of an ideal realism, if the characters portrayed could reach to high mental types, if the subjects chosen embodied the best thoughts current in the age; if, as in days of old, we could make our art a thank-offering of what was rich and rare in our substance. At all events, any man possessing genius for the new work would doubtless find some new mode of utterance scarcely inferior to the old.—*Saturday Review.*

A committee has been formed at Swindon for the establishment of a school of art there.

CONCRETE STABLES.

To the Editor of the BUILDING NEWS.

SIR,—The annexed plan and elevation of stable buildings, with enclosed stable yard, house, &c., for poultry, recently built about twenty miles from London, with walls of concrete, and fireproof floors to rooms above, may be of interest to many of your readers as showing the comparison in cost of walls of brick *versus* walls of Portland cement concrete.

The building is 45ft. 6in long, 16ft. 6in. wide, and 16ft. high to roof, comprising two-stall stable with loose box 2ft by 15ft., divided from the harness room by a 9-inch wall, coach house 14ft. by 15ft., divided also from the harness room by a 14in. wall carried up through the roof and forming the chimney stack.

The rooms above are a loft over stable 29ft. by 15ft., with outside door at gable end, and door from roof over harness room, gardener's room over coach house, with entrance door at gable and outside approach step ladder with rails.

The stable yard is 40ft. by 21ft., a portion is devoted to three rooms for fowls, communicating with three feeding yards outside, with roof over, and in juxtaposition with three separate and one large exercising yard, with sides and top enclosed by galvanised wire.

The stable buildings, with walls of 9in. or one brick in thickness, and proper footings in 1½ bricks, would absorb 31,500 bricks, viz., about 7 rods of reduced brickwork, according to the London standard of 272ft. super of 1 brick to a rod; say, cost of bricks delivered at 30s. per 1,000, £6 15s. per rod; ditto lime and sand, labour and scaffolding, £3 10s.: total cost per rod, £10 5s. This will show for the 7 rods the sum of £71 15s, and, with the bricks at 40s. per 1,000, £87 10s. The walls contain 2,660ft super of 9in. concrete, and where the materials for making the concrete—viz., the stones, gravel, sand, or brick ballast can be delivered at a moderate price, the cost would be from 2s. to 2s. 6d. per yard super—say 2s. 3d. This will give the cost of walls £33 6s., with the advantages of a wall material impervious to moisture, and of strength equal to granite.

There are many localities in which the external walls should be 1½ brick thick, to keep out the damp, thus adding one-third more to brick walls.

Should it be desirable to stucco the outside of the walls with Portland cement and jointed, the cost would be 4d. per yard super to stable buildings—2 6 yards, £4 19s.—requiring only a thin skin of one of cement to four parts of sand.

By forming rebates in the thickness of the walls, and inserting dove-tailed wood blocks, or iron hooks, to receive the hinges and fastenings, door frames of wood are dispensed with.

The wall between coach house and harness room is 14in. thick. The chimneys, with their gathering throats to lead into the circular flues, require no projecting breast. A space is left at the back of the range in the harness room to send warm air into the coach house.

The entire floor throughout the stables, &c., is finished with a coat of Portland cement on a bed of concrete, at a cost of 3s. per square yard—£10 10s.

The floor above is fireproof, formed by 12 iron joists, 16ft. long, £8; 15 segmental corrugated galvanised panels, £17; Portland cement finish on concrete, £7; total, £32. The corrugated panels, as above, are an unnecessary expense; they look well, but level panels of concrete or segmental would look as well.

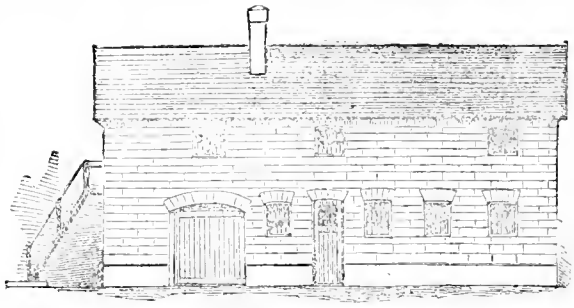
It would be occupying too much of your valuable space to go into other details, such as the slate roof with the wood framing to receive the same; also the fittings to stable in the stall divisions, or fittings of manger, racks, &c. Over the head of each stall a square of stout fluted glass is placed near the ceiling 2ft. by 1ft. 6in. to give additional light for the horse to be accustomed to. All the windows are of iron, and hang on centres; those below are two in height. In the stable lobby is fixed the pump, with sink; over the same is a cistern, with a supply pipe to coach house. The coach house door and entrance gates are not made folding, as when so made they are very inconvenient in windy weather.

The economy of concrete for walls, when bricks are 30s. per thousand, equals a saving of more than half. It is admirably adapted for farm buildings, such as stables, cattle sheds, &c., and block model dwellings in cities and towns, being approved by the Metropolitan Board of Works as suitable for all kinds of dwellings. Block buildings, decent and healthy, may be provided in the country so as to let rooms from 6d. per room per week, and in cities from 9d. per room per week.

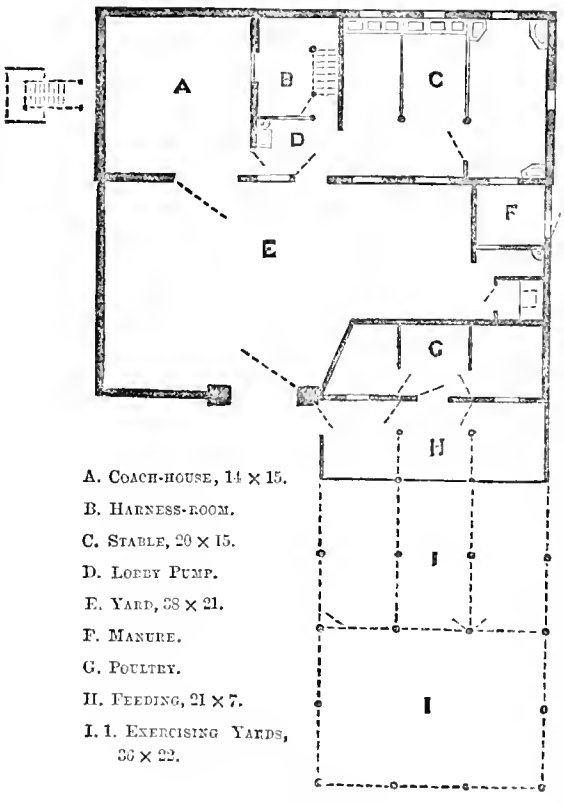
24, High street, Marylebone. PETER THOMPSON.

Total Cost of Coach House, Stable, Harness Room, with three rooms over, viz., Loft with iron corn bin, Groom's and Gardener's Rooms.

	£	s.	d.
To excavate for foundations and manure pit, and concrete walls	36	0	0
To floor to stable, coach house, harness room, and finished Portland cement on concrete	10	16	0
To iron surface drains to stalls, with iron traps to glazed drain pipes to manure pit, and drain from sink in lobby	5	10	0
To fireproof floor, iron joists, with segmental galvanised corrugated iron and concrete, finished with Portland cement	27	10	0
To framed wood roof, with gable boards	11	15	0
To countess slating on battens, with slate ridge roll	21	16	0
To metal gutters and down pipes	3	15	0
To iron posts and rails, with tongued boards to stalls, and framed door to loose box, with brass flush fastenings	16	10	0
To iron mangers, racks, &c., as fittings	10	18	0
To seven iron windows, and ventilating bricks	7	6	0
To glass to ditto, and in lobby glazed	3	19	0
To stairs, shelves, rails, and doors to harness room	6	10	0
To saddle and collar brackets, harness pads, hooks, &c.	3	10	0
To 3-inch coach-house door with weighty hinges, to framed door to stable with brass flush fastenings, and two outside doors to rooms over and step-ladder	14	16	0
To iron corn bin in loft with down pipe measure	6	10	0
To plastering walls and ceilings	24	16	0
To staining wood and varnishing, painting iron	11	19	0
To a lift pump (not including a well) a sink with cistern above, and service pipe to coach house	12	16	0
To a range with boiler in harness room and two cottage stoves in rooms over	4	15	0
	£240	9	0



ELEVATION OF STABLE, &c.



A. COACH-HOUSE, 14 × 15.
B. HARNESS-ROOM.
C. STABLE, 20 × 15.
D. LOBBY PUMP.
E. YARD, 38 × 21.
F. MANURE.
G. POULTRY.
H. FEEDING, 21 × 7.
I. I. EXERCISING YARDS, 36 × 22.

PLAN OF STABLING, &c.

ARCHÆOLOGY.

ON Saturday week, as the ironstone diggers on Mr. E. Jones's farm at Wellingborough, were excavating, they came upon a well, which, on being emptied of the thick water, was found to contain (besides bones of what seem to have been deer, &c.,) the remains of several Roman urns. One of them is perfect, and one a very large unburnt one, with a piece broken out of its side; when whole the shape must have been handsome. They are in the possession of Mr Cramp, the overseer of the works. The well is neatly lined with limestone, and has a sloped bottom. From the above description it appears that this is one of the so-called "sacrificial wells," several examples of which have been found in Oxfordshire, Stone in Bucks, Biddenham and Sewell in Beds., &c. One theory is that these were kept for the deposit of the remains of sacrifices and other objects held in veneration.

Recently, the excavators employed on the new West Dock Works, Hull, when digging just where the outlet of the limekiln used to be, about 16ft. below the surface, turned up a hard lump, which, on examination, proved to be some hundreds of small silver coins—halfpennies of the reign of King Edward I. When first discovered the coins looked quite fresh, but on exposure to the air, they changed to a yellowish tint. Some of them appear to be counterfeit, and others are a mixture of silver and copper; a few are doubled. The soil in which the coins were found was an amalgam of warp and gravel, and the spot where they were digging up appears to have formerly been the boat channel near the mouth of the River Hull, previous to the warping up as narrated by old historians, and prior to the time it was diverted into its present outlet through Sayer's Creek, the harbour of the present day. Another interesting discovery has been made in connection with the works now in progress for the Dock Company. In clearing away for the foundation stone of the new dock offices, near the Wilberforce monument, a portion of the old moat, which formerly surrounded the town, and of a brick arch connected with the historical Beverley Gate, were brought to light.

WATER SUPPLY AND SANITARY MATTERS.

A CONFERENCE of three Local Boards at Leamington has decided to unite the three parishes for sewage purposes. It was also decided in favour of irrigation, in consequence of the failure of the lime deodorising process, and the threatened injunctions against the pollution of the river by a sewage outfall. 400 acres are said to be necessary for irrigation purposes, and the works will cost about £40,000.

Building Intelligence.

CHURCHES AND CHAPELS.

The new church of St Clement's, Leeds, was consecrated yesterday week. The plan consists of nave, north and south aisles, apsidal chancel, with organ chamber and vestry. A tower at the south-east angle rises to a height of 122ft. The nave is 88ft. long by 29ft. 6in. wide. The cost of the church is about £8,000. Mr. George Corson, of Leeds, was the architect.

On Tuesday week a new church was opened at Treherbert, Rhondda Valley, Glamorganshire. The building is in the Early English style, and comprises nave, north and south aisles, chancel, and north chancel aisle. Local stone is used for the exterior, with Bath stone dressings, and the interior is of red and white bricks. A "saddle back" tower, 80ft. high, will complete the edifice. Mr. C. Buckeridge, of London and Oxford, is the architect.

The parish church of Norton, Radnorshire, was reopened on the 10th inst., after restoration. The style of the building is Early English, the plan consisting simply of a nave parted at the east end by a rood screen to form a chancel. The whole of the interior has been restored, and a small transept let in by means of low turned pointed arches. The building has also been entirely re-seated. The cost of the work was £2,200. Mr. G. G. Scott, of London, was the architect, and Mr. Coleman, of Claxhill, near Gloucester, the builder.

A new Free Church was opened at Gilcomston, Aberdeen, on Sunday week. The style is Early Decorated, the walls being of hammer-blocked granite, with freestone dressings. The tower and spire, when complete, will attain a height of 145ft. At the south-east corner is an octagonal tower, 75ft. high. Exteriorly, the church is divided by buttresses into six bays, a triplet window in each bay affording light to the interior. The internal length, exclusive of vestibule, is 80ft., and the width 54ft. 6in. The height from floor to apex of roof (which is open-timbered) is 47ft. A gallery runs round three sides of the building. Sittings are provided for 1,200 persons. The building is from designs by Mr. Smith, city architect. The cost has been £4,786 13s. To complete the spire £1,000 more is required.

On Saturday last the foundation stone of a new Roman Catholic Church was laid at Great Ancoats, near Liverpool. The style of the building, which is dedicated to St. Michael, is Early English, and the plan consists of nave, aisles, chancel, lady chapel, and sacristy. The length will be 87ft., the breadth 61ft., and the height of bell turret 71ft. 6in. Accommodation will be provided for 1,000 persons. Mr. W. Nicholson, of Liverpool, is the architect.

The inhabitants of Yoxford, Suffolk, have determined to re-seat and otherwise improve the interior of the parish church. The building, which is in the Perpendicular style, was considerably enlarged and restored about thirty years ago, at a cost of £12,000, and 430 additional seats were then provided. It has now been determined to take down the old-fashioned pews and to replace them with open benches.

The new church at Houghton, Notts, erected from the design of Mr. James Fowler, of Louth, by Mr. Hopkinson, builder, of Retford, was formally opened on the 15th inst.

The parish church of Llechgynfarwy, Anglesey, which is dedicated to St. Cynfarwy, was reopened for Divine service on August 21, after having been rebuilt almost from the foundations. The style is Late Decorated, or Second Pointed. The church is seated for 105 worshippers, and is fitted up with open seats, which are lightly stained and varnished, as are all the internal fittings. The plans, &c., were prepared by Messrs. Kennedy and O'Donoghue, architects, of Bangor, and Albion-chambers, 11, Adam-street, Adelphi, London, and the work carried out under their supervision.

The foundation stone of a new Presbyterian Church at Portadown was laid on the 8th inst. by the Duke of Manchester. The church will be in the Gothic style, and will present a neat front to the Armagh road. The material to be used for walling will be the black or whinstone of the locality, with Dungannon freestone dressings to doors, windows, buttresses, &c. Accommodation will be provided for about 300 persons. Messrs. Boyd and Batt, Belfast, are the architects, and Mr. John Cullen, Portadown, the contractor.

The new parish church of Holmpatrick, near Skerries, Co. Dublin, was consecrated on the 2nd inst. by the Archbishop of Dublin. It is in the Gothic style. The material is limestone from the Milverton quarries. Mr. James Rogers was the architect, and Mr. Walter Doolin the builder.

St. Wilfrid's Church, Alford, Lincolnshire, was reopened on Thursday last, after undergoing enlargement and restoration. The plan of the church comprises a nave 59ft. long by 20ft. wide, divided into four bays by arcades of octagonal columns and deeply moulded arches, having north and south aisles 9ft. wide, and a new north aisle 16½ft. wide. The chancel is 44ft. deep by 20ft. wide. A massive tower stands at the west end of the nave, 17ft. square within. The entire length of the church is 125ft. 6in.; width, 62ft. There is a large porch on the south side, with vestry above for choristers, &c. The style adopted is that of the thirteenth century, or Second Pointed, the windows and other details being as nearly as can be ascertained of the date of the original church. The arches of the nave and chancel are richly moulded, having foliated capitals and moulded bases. The tracery in the chancel windows is to be filled in with the remnants of the old stained glass. The roofs are open, high-pitched, and stained and varnished. The chancel roof is of stained oak, and of the waggon-head shape. The old rood screen at the entrance to the chancel is to be repaired and retained. The seats are all open, of pale oak, with carved ends. The middle aisle is flagged with ancient tombstones, and the other aisles are paved with red and black unglazed tiles, from Godwin's works at Lugwardine, near Hereford. The windows are glazed with pale green cathedral glass, and the roofs are covered with pale Westmoreland slates, having moulded stone ridges. The wrought-iron hinges to doors and the gas pendants, &c., are from the works of Messrs. Peard and Jackson, of High Holborn. The new organ, by Forster and Andrews, of Hull, has cost £400. At the eastern end of the south aisle there is a piscina, with shelf, and at the east end of the north aisle there is an aumbrey, and several steps formerly leading over the rood screen. There is also a hagioscope or squint, to enable those sitting in the north aisle to see the east end of the chancel. The dark green sandstone used is from the quarries at Welby, the light stone for the angles, mullions, &c., being from Ancaster. The new gurgoyles and beads on the corbel stones have been carved by Messrs. Ruddock, of London. Sittings are provided for 600 persons. Mr. G. G. Scott is the architect, and Messrs. Hasnip and White, of Alford, the contractors. The total cost of the restoration and enlargement has been £6,200.

BUILDINGS.

On Friday last, the foundation stone of a new building intended to take the place of the well-known old Whitfield's Tabernacle, in Moorfields, was laid by Mr. J. Remington Mills, M.P. There was a large attendance of the leading Nonconformist ministers.

At the last meeting of the Marylebone Board of Guardians plans for extensive alterations at the workhouse were submitted by the architect. The plan adopted (subject to the approval of the Poor Law Board) provides increased accommodation for 100 inmates, at a cost of £2,500, 750 cubic feet of space being allotted to each inmate.

On Tuesday week the foundation stone of a new public hall was laid at Antrim. The dimensions are—length, 63ft.; breadth, 42ft; height, 2[illegible]ft. It will consist of two committee rooms and a large assembly room capable of accommodating about 1,000 people. Block stone will be used in the erection, and the style of architecture is to be Doric. Messrs. Young and Mackenzie are the architects, and Mr. W. Vance, sen., is the contractor.

A new fever hospital, containing twenty-four beds on the ground-floor and five small wards above, has just been erected at Chester, in connection with the general hospital. The cost is £2,500.

The new Hop and Malt Exchange, Southwark-street, was opened on Monday for business. The sculpture work in pediments and all the other carving have been executed for the architect by Messrs. Frampton and Williamson, of Fulham. We have made some observations on this building before, and shall allude to its architectural pretensions again next week.

The Sunderland Gas Company opened their new offices on the 9th inst. They occupy a conspicuous position at the south west corner of Fawcett-street, one of the finest sites in the borough, and are erected from the design of Mr. G. G. Hoskins, architect, of Darlington and Sunderland, who obtained the first premium in a public competition in March, 1867. The style of the building is Gothic, and is dependent for its effect rather upon breadth of treatment of the whole than the elaboration of parts. It has a bold and commanding appearance, and is indicative of the purpose it fulfils. The materials employed are red pressed bricks, with Dunhouse stone dressings. The whole of the windows and principal entrance doors on the ground-floor have segmental pointed heads, those of the doorways being very deeply recessed and furnished with columns of grey Dalbeattie polished granite, with carved caps of Dunhouse stone. The south front or principal elevation occupies a frontage of about 80ft. towards the Borough road, and is distinguished by a noble oriel window, supported by a stone buttress and bold shaft of grey Dalbeattie polished granite, which is surrounded by a carved cap representing a group of ferns. On the ground floor the following accommodation is provided, viz., public offices, 33ft. 3in. by 22ft.; secretary's office, 24ft. 4in. by 17ft. 3in.; outdoor manager's office, 17ft. by 15ft.; meter inspector's office, 14ft. by 13ft.; principal or directors' entrance from Fawcett-street, 26ft. 6in. by 10ft.; strong rooms, with iron doors by Chubb; lavatories, water-closets, &c. The first-floor comprises directors' room, 33ft. 3in. by 22ft.—this room has a handsome panelled ceiling and an oak dado 3ft. 6in. in height, the oriel window forming a good feature; photometrical and experimental room, 17ft. 3in. by 13ft.; meter warehouse, 35ft. 1in. by 15ft.; book room, lavatories, &c.

TO CORRESPONDENTS.

NOTICE.—Cases for binding the BUILDING NEWS, Vol. XIV., are now ready, price 2s. each.

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

RECEIVED.—A and G. T.—D. B.—B. and Co.—W. C. B.—B. and P.—A. P. B.—I. W.—I. A. H.—P. E. M.—I. C.—W. D. and E.—G. H. G.—R. C.—C. L.—I. A. H.

A. P. B.—Thanks for sketch of Ambone, which will appear—details not wanted.

Correspondence.

THE ST. ANDREW'S CHURCH, HERTFORD, COMPETITION.

To the Editor of the BUILDING NEWS.

SIR,—According to the rules furnished to the competitors, this church was to cost £3,000. The lowest tender for the design accepted is, it appears, £4,300. Now the committee may be quite certain of this, that it is simply impossible to reduce the cost of the building from the latter sum to that originally stated without sacrificing the integrity of the design in every way—materials, construction, ornament, and accommodation. It is evident that the design as submitted in competition cannot be carried out, and therefore, as a matter of common sense and honesty, the next eligible competitor should take his stand for the same ordeal. It is a common thing for competitors to send in designs which they know cannot be executed for the sum specified, and it is a great pity the trick should ever be successful. My experience of competitions is this, that the more conscientious a man is the less chance of success he will have. The great fault in competitions is the want of honour in those who compete.—I am, &c.,

FAIRPLAY.

SIR,—In answer to "Fairplay," I beg to state that the instructions of the above competition have not been ignored by me, therefore I consider no unfairness has been done to the other competitors.

With regard to the cost, I have received tenders from most respectable builders, which have been forwarded to the committee. The amounts I am not, of course, in a position to state. However, I can assure your anonymous correspondent, who has no personal interest in the affair, that I believe he will be quite satisfied when he knows more about the matter than he does at present.

As to the requirements, my design provides sitting accommodation, allowing 20in. for adults, for about 630.

"Fairplay" merely assumes that it is quite clear that the design cannot be carried out for anything like the money unless considerably altered or reduced. I can only say that it would be impossible for me to alter my design without the sanction of the committee, and it not being necessary to alter my design, such sanction has not been asked for; therefore it has not been granted. I may add that several copies of my design (about 40 drawings altogether) were made in June last; some of them have not been in my possession since.

I should be very glad to see a little more fairplay after as well as at the time of a competition. The profession, in my opinion, require reforming quite as much, if not more, than committees. The sharp practices (this is a very mild term for them) resorted to by architects during a competition considerably lower the reputation of the profession in the estimation of the public.—I am, &c.,

JOHN JOHNSON.

35, Moorgate-street, E.C.

WESTMINSTER ABBEY AND ITS ORGAN.

SIR,—Your correspondent "C. B. A." finds fault with the removal of the Abbey organ from its old position on the screen to its present *locale*, and even goes so far as to designate the act of removal a "stupid blunder." He further condemns the very object to effect which the change of site was made, viz, "to open out the Abbey and exhibit to greater advantage its Gothic proportions." Now with respect to the musical effect of the instrument being impaired I cannot agree with him. Who that has often attended service in the glorious old minster but can dwell with a thrill of emotion on the subdued harmony of the diapasons rolling through the building, eddying from column to column, streaming along the vaulted aisles, and then losing itself in the lofty nave? If the organ were replaced as it formerly stood, a great portion of the enchanting dreaminess its music now has would be lost; the sound would not be so beautifully diffused as it is, but dash on the ear at once, with but half the solemnity it now has. I do not mean to defend in all instances conformity with the existing fashion of placing organs in chancels, whether fitted to receive them or not, either on musical or architectural grounds, the splendid instrument at the Temple Church being quite smothered in its stone box. But with the Abbey the case is different; there there is ample space for the sound to radiate in every direction. It does not follow, either, that the "swell" does not act because the organ is divided; nor for that reason need the organist be separated from the "quoir," as your correspondent delights to call it. The loss of the accidental echo of the "swell" from the western wall may be one of those minor evils with which every good thing is sure to be accompanied, but if "C. B. A." would only consent to ornament the western wall for a day or two, Dean Stanley might be gratified with the thing itself instead of a mere echo.

As to the architectural effect of "this stupid

blunder" I have also somewhat to say. "Opening out" is simply Gothic destroyed, so at least says "C. B. A."; then, Mr. Editor, pray use your potent influence to get all the old galleries of the pious times of the Georges restored, cause high backed pews once more to reign triumphant, let the nave and the choir of the venerable old Abbey of Selby be once more divided by tiers of deal boxes, and pray let a few more screens add "confusion and mystery" to the length of St. Albans. What a pity the division walls of Cologne have been removed; but there is one consolation yet left for "C. B. A." He has only to travel as far as Beauvais, and there he may have "confusion and mystery" to the end of time. The whole building cannot be seen at once, for there is no nave beyond the walled-up transept, and never will be. Only think of the scope for imagination, and picture the giant nave extending until stopped by the waves of the Channel!

In sober earnest, each case must be judged on its own merits, for while the wondrous beautiful proportions of the old Abbey are "opened out" by the transference of its "kist of whistles" to another site, hardly any excuse can be given for the contemplated removal of the fine old instrument at St. Stephen's, Walbrook, which so fitly fills the position the celebrated architect of the church intended that it should.

Permit me to finish by expressing a hope that the "authorities" at St. Paul's may some day act with a little of the judgment displayed by those at Westminster. W. C. J.

HOW A DESIGN WAS OBTAINED FOR A NEW LOCK-UP AT MORETONHAMPSTEAD, DEVON, AND HOW IT WAS LOST AGAIN.

SIR,—Your columns being always open for the exposure of abuses in our profession I make no apology for sending you particulars of the above, which tend to show how plans are not unfrequently obtained, and at the same time exhibit a degree of parsimony paramount to all other considerations, and seldom equalled in connection with the carrying out a public work. It being decided to erect a new police station with residence for the constable at Moretonhampstead, the magistrates of the Crockernwell division of the county, acting under the powers of the quarter sessions, appoint a working mason and another, I believe a carpenter, to make the requisite drawings, the cost of which is not to exceed £5! Now these men knew nothing whatever of drawing, but I suppose, not liking to expose their ignorance, they undertake to make plans. What course do they adopt? Why they, on their own responsibility, consult an architect, who prepares drawings which in due course are submitted to the magistrates, and subsequently to the county surveyor, for examination, and are ultimately approved of by them. They are then forwarded to the Secretary of State, who reports he cannot consent to their adoption unless the cells are enlarged as recommended by the Surveyor General of Prisons. The plans are consequently returned to the before-mentioned workmen, and in due course again find their way into the hands of the architect for amendment.

The architect having got possession of the plans and feeling his position to be a most improper one, applies to be engaged by the justices in the usual way as architect of the building, and this not being complied with, the plans are consequently withheld. It remains to be seen what course the justices will further take that they may obtain plans for the paltry and ridiculous amount offered by them for a building, the cost of which will be from £500 to £600 at least. More than twelve months have elapsed since the project was started. Had the matter been placed in proper hands in the first instance the building would have been nearly finished. If the same system of jobbery he pursued another twelve months will probably expire before the building becomes a reality.—I am, &c.,

OBSERVER.

The Winchester Town Council have a very unique method of providing funds for a holiday. On Monday week they had an excursion to Netley Abbey, the object being "to spend the amount of fines received from those who have during the year neglected to attend the monthly meetings of the local board." An excellent dinner, well washed down with champagne, was partaken of by over twenty persons. The non-attendants must either be very numerous or the fines very heavy.

Intercommunication.

QUESTIONS.

[1015.]—METHOD OF CALCULATING.—Thinking that the knowledge of two or three short and at the same time accurate methods of calculation may not prove wholly useless to the readers of this journal, I append the following, which, in working out some problems, I lately discovered. To find the length of the side of an octagon from the diameter of the inscribing circle, let—

d = diameter of inscribed circle,
z = required length of side of octagon.

$$x = \frac{d}{6}$$

$$z = \frac{d - x}{2}$$

To find the length of the side of a pentagon from the diameter of the circumscribing circle, let—

d = diameter of circumscribing circle,
x = required length of side of pentagon.

$$x = \frac{d + \frac{d}{6}}{2}$$

To square any whole number up to 100. Given a certain number 47. Square units and tens separately, bringing the product into four figures, thus:

1649
56-

2209 Answer.

And to this amount add double the product of the two figures composing the given number 47, leaving the space under the units open. When the square of the units only amounts to one figure, a cipher is always placed before it, proceeding the same as in the foregoing, thus:

$4^2 3^2 = 1609$
24

1849 Answer.

A. P. B.

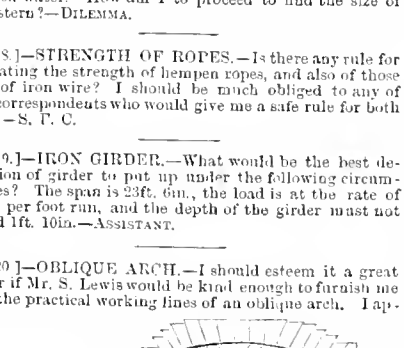
[1016.]—SKEW FACING TO ARCHES.—Can any of your correspondents inform me how I am to find the templets for cutting the face stones of a skew arch to the proper line? The arch is built on the square in brick, but stone rings are put in at the two faces. I want to know how I am to obtain the templet for cutting the rings, so that they will range properly with the direction of the face, which, of course, is parallel to the road above.—CONTRACTOR.

[1017.]—CONTENTS OF CISTERN.—Will you be so good as to insert the following in your valuable column of "Intercommunication":—For years my supply of water for the house has been stored in an enormous butt. Owing to some alterations in the house, I am about to replace it by a cistern or small tank, which I want to contain three times as much water. How am I to proceed to find the size of the cistern?—DILEMMA.

[1018.]—STRENGTH OF ROPES.—Is there any rule for calculating the strength of hempen ropes, and also of those made of iron wire? I should be much obliged to any of your correspondents who would give me a safe rule for both kinds.—S. T. C.

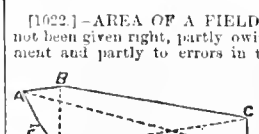
[1019.]—IRON GIRDER.—What would be the best description of girder to put up under the following circumstances? The span is 23ft. 6in., the load is at the rate of 6 cwt. per foot run, and the depth of the girder must not exceed 1ft. 10in.—ASSISTANT.

[1020.]—OBLIQUE ARCH.—I should esteem it a great favour if Mr. S. Lewis would be kind enough to furnish me with the practical working lines of an oblique arch. I append a plan for his guidance. By so doing he will greatly oblige.—EXCELSIOR.



[1021.]—LINING RESERVOIRS.—I have often seen asphalte recommended in the "Intercommunication" column for lining reservoirs, so as to make them watertight. Would anyone inform me of the method of laying it on, and of the proportion, and of what it is compounded?—NEMO.

[1022.]—AREA OF A FIELD.—As the dimensions have not been given right, partly owing to incorrect measurement and partly to errors in the figures, I give what I believe to be the correct length of the lines, A B and A F equal each 196ft.; F E = 165ft.; B E 320ft.; A D = 1170ft.; B C = 930ft.; E C = 945ft.; E D = 940ft.; and D C = 185ft. Allow me to add that your correspondent "R." is too hasty in his suppositions. I should be obliged to "J. M'Namara" if he would inform me how to get at the total contents, as I do not quite comprehend those attempted to be given.—YOUNG SURVEYOR.



REPLIES.

[987.]—TRUSS.—From indistinct writing on my part, or some other cause, there are two misprints in my reply last week to the above, which, if not corrected, may confuse "Beginner" in interpreting my explanation. The first is in the figures giving thrust of rafter, where $\frac{20\text{cwt.} \times 9\text{lb.}}{5 \times 2}$, &c., as printed, should be "20cwt. × 9ft.," &c.; the 9ft. being the length of rafter. And the second:—In the fifth line of text from top of page where "simply *by* its own weight," &c., should be "simply its own;" that is, it would have to support only its own weight and that produced by the tendency of the tie-beam to sag (as more closely explained by "W., Tenby," in his reply of the same date) by its own weight, which, in the case under notice, would give even le s weight than I mentioned in my reply of last week.—A SUBSCRIBER.

[1001.]—PLAN DRAWING.—Would you allow me to call "Stonemason's" attention to the fact that if he intends purchasing "Gwilt's Encyclopædia," there is a copy for sale at the second-hand book shop opposite St. Clement Danes church, in the Strand, which I think was marked 12s. or 14s. 6d.; cheap, if it is perfect, which he can prove by inspection, if not already sold.—SUBSCRIBER.

[1004.]—TELESCOPE GLASSES.—It is in order to save the necessity of an extra glass that the telescopes of all surveying instruments view the objects inverted. This will be seen at once from the cut. Let A be the object glass, B the eye glass, and C the object viewed. The object is shown inverted in the focus of the eye-glass. Were it

desirable to view the object erect, it would require the aid of another glass to invert the image shown at B. As every glass is a source of some obscurity and indistinctness, the fewer that are employed the better, and a little practice soon renders the beginner accustomed to the method.—LEVEL.

[1005.]—FREEZING MIXTURES.—The theory of all freezing mixtures is that the ingredients, in their act of chemical combination, absorb so much heat, which becomes converted into what is called "latent heat," that their temperature is at once lowered. The commonest freezing mixture is snow and salt, which produces an amount of cold sufficient to freeze water almost instantaneously.—CHEMIST.

[1006.]—MOIST WATER COLOURS.—"H. K." can obtain what he wants at Windsor and Newton's colour warehouse, Rathbone-place, High Holborn.—ARTIST.

[1009.]—ADDRESS WANTED.—The address wanted by "Alpha" is Messrs. Paley and Austin, Castle Hill, Lancaster.—H. J. A.

[1013.]—PARTY WALLS.—In answer to "H. R. T.," I should very much doubt if a larger opening could be legally made, although the wall might certainly be rebuilt with the former opening in it.—CLERK.

BUILDING AND LAND SOCIETIES.

THE first annual general meeting of the Monarch Building Society was held on Monday evening at the London Tavern—Mr. J. Duncan in the chair. The society had during its first year invested upwards of £80,000 upon undeniable and real security. The directors, after paying 5 per cent. on all share capital, interest on deposits, preliminary and general expenses, had a surplus of profit amounting to £4,785 to carry to next year's account. It was also stated that next year the society will be able to declare a bonus of 10 per cent. The report was adopted, and the retiring directors and auditor re-elected.

The directors of the Bristol Equitable Permanent Building and Investment Society in their eighteenth annual report, congratulate their shareholders on the prosperity of the society. After providing 5 per cent. compound interest to all investors, and paying the working expenses, there is a surplus profit of £156 3s. 11d. for the year on the profit and loss account; also, a surplus profit of £147 5s. 9d. on the contingent fund account; and also a total profit of £466 14s. 5d. on the guarantee fund account. The number of new shares issued during the past year is 425, and the amount advanced to borrowers for the same period is £15,209 11s. 11d., being more than double that of any previous year. The total income of the society up to the year now ended is £79,972 7s. 11d. as against £60,299 7s. 5d. of the preceding year.

LEGAL INTELLIGENCE.

THE question "What is a smoke nuisance?" was raised in a curious manner at the County Magistrates' Court, Bassett-street, Liverpool, on Saturday last. The officials of the West Derby Local Government Board were prosecuting the proprietors of several works (amongst them the Corporation of Liverpool as owners of the Green-lane waterworks) for alleged smoke nuisances. As, however, the prosecutors' inspector could not say that the dense smoke had continued for more than five minutes, and admitted that, generally, it had continued only three or four, the magistrates on the bench held that this was not such a nuisance as should incur a penalty. The board's legal representative pointed out that the court on previous occasions—when other magistrates had presided—had held five minutes dense smoke to be a nuisance within the terms of the Act, and had inflicted penalties; but the gentlemen then on the bench maintained their own view and dismissed all the informations on the ground stated. There was some talk of having the matter settled by a higher tribunal.

BREACH OF CONTRACT.—LUND *v.* LUCAS.—This was an action in the County Court, York, for the recovery of £10 2s. 4s. for breach of covenant. The plaintiff, on February 14, 1862, purchased a portion of building land

of the defendant, and the deed contained a covenant that defendant should complete the road to it when necessary. A house No. 19, Park Crescent, now stands in their ground, and, as the defendant neglected to perform his agreement with reference to the road, the Local Board of Health had done the work and charged plaintiff £10 2s 4d for it, which he now sought to recover. Mr. Mann, for the defendant, admitted the covenant, the payment of £10 to the Local Board of Health, and that his client did not pave the road as required in the covenant, but he submitted that in 1861 the defendant made an assignment, and in consequence he contended that his client was not liable for the amount claimed. His Honour ruled that to set up a plea of bankruptcy it must be proved under the bankruptcy and gave a verdict for defendant.

AN ARCHITECT'S COMMISSION REDUCED.—HARRISON *v.* C. H. STEIN.—This case was heard at last sitting of the Hartlepool County Court. The claim was for £21 12s 8d, commission to plaintiff, as architect, for superintending the erection of West Hartlepool Theatre; the defence being that the duties were inefficiently performed, and the building placed in jeopardy by being based on an insecure foundation.—His Honour decided that the plaintiff had not exhibited that precaution which was desirable, by not informing the defendant of the character of the foundation. Under those circumstances, his Honour allowed commission with a deduction of two fifths, making the sum payable £3 1s.

OBSTRUCTION OF LIGHT AND AIR.—At the Keighley County Court, on Wednesday week, Mr. W. T. S. Daniel, Q.C., the judge, gave judgment in an action, brought and heard on August 5 last, by Mr. Joseph Fieldhouse, of Keighley, against Mr. John Hartley, comb maker, and Mr. John Craven, of Steeton, J.P., who were trustees of certain property to recover damages from the defendants for taking away and obstructing the free access of light and air to two of the plaintiffs' cottages. The Judge observed that the plaintiff had shown by evidence that the windows, the obstruction of which was complained of, were ancient ones and had existed for upwards of fifty years. The cottages, it also appeared, were originally erected by the plaintiff's father on waste land, and for many years an annual rent had been paid as an acknowledgment to the Duke of Devonshire, from whom, in 1864, the plaintiff, after his father's death, had purchased the fee simple in the land. It was also shown that Joseph Hartley, from whom the defendants took their estate, in 1851, erected the buildings, which were now complained of as causing obstruction, with the knowledge and consent of the Duke of Devonshire's agent, and that they had ever since been continued. A complaint had been made, but no action was brought until the present. On these and other grounds the judge ordered judgment to be entered for the defendants, with the usual costs.

Our Office Table.

No. 71, Leadenhall-street, opposite Aldgate pump, will shortly be pulled down for city improvements. Under these premises, and at a depth of about four to five feet, are the remains of the ancient crypt of St. Michael's Church, Aldgate, a beautiful Gothic structure in an excellent state of preservation. It measures north by south 46ft. in length, and east by west 17ft. in breadth. The walls are of square pieces of chalk, in the manner of Rochester Castle, and the arches of stone exhibiting as skilful masonry as anything in this age of refinement.

The Tower subway, which we described and illustrated some months back, will be shortly commenced. The engineer (Mr. P. W. Barlow, jun.) reports that numerous borings have been made in and near the line of tunnel, all indicating that it will be everywhere deep in the solid London clay, and that no water is likely to be met with. A tender has been made to execute the tunnel and shafts entirely in iron for £9,400.

We regret to learn the death, at Capri, in the Bay of Naples, of Mr. J. T. Hixon, a young water colour painter of considerable promise. He was known chiefly by his drawings of Algerian subjects, and was recently admitted as associate of the Institute of Painters in Water Colours.

Green pigments, says "Once a Week," have been in such bad odour for years, on account of their real or imagined poisonous influence, that chemists have laboured hard to find a form of the favourite colour that shall be above suspicion. Success appears to have crowned their experiments at last, for we are told that a new preparation of a salt of chromium yields a green colouring powder that leaves little to be desired. It is brilliant in tone, perfectly harmless, and possesses other requirements of technical character. It will be known, when it is known, as "Imperial Green."

The *Boston* (Massachusetts) *Advertiser* records the death of Mr. Charles Loring Eliot, which took place at Albany, on the 25th ult. He was one of the best known of American portrait painters.

The library shelves of the British Museum, if placed in a continuous line, would extend no less than twenty-five miles. The accession of books keeps growing at the rate of 20,000 volumes a year, or between 50 and 60 a day.

The town of South Danvers, Massachusetts, United States, has resolved to change its name to "Peabody," in honour of the charitable millionaire who was born there.

Over 150,000 of Cliff and Son's white glazed bricks have been used in Messrs. Nelson and Son's new premises in Paternoster-row. The whole of the interior is lined with them, producing a good effect and giving the greatest amount of light. They are fireproof, and supersede the use of plaster, paper, match lining, or any other wall lining.

Yesterday week the "rearing" of the Rochdale Townhall was celebrated by a supper to the workmen in the Assembly Room over the co-operative stores. About 200 men in the employ of Mr. Warburton, of Harpurhey, the contractors, were present, and spent a very merry evening. Mr. W. H. Crossland, of Leeds, is the architect of the building.

In consequence of a competition opened by public notice for the plans of a new cathedral at Berlin, forty-nine have been sent in, and amongst them several furnished by French architects. The award has not yet been made.

The tender of Mr. Rider has been accepted for the enlargement of the Essex County Lunatic Asylum. The amount of the contract is £18,560.

Builders, allotment gardeners, and others who employ home-grown timber for fencing and other purposes, will be glad to hear that an effectual preventative for the "dry rot" has been discovered. The recipe is forwarded to the *Gardeners' Chronicle* by Mr. J. Baily Denton, and has been thoroughly tested by experiment. It consists in soaking the timber for a short time in lime water. A pit or tank or good-sized barrel, according to the extent of requirement, will answer the purpose, the lime being added to the water in the proportion of eighty-eight grains to one gallon. Timber creosoted in this way stands the weather remarkably well, and is not subject to the decay to which unprepared timber is so liable.

About 70,000 tons of clay from the Purbeck Hills are annually exported from the port of Poole, Dorsetshire. This clay is adapted for the manufacture of coarse earthenware. Some portion of the clay is shipped to foreign ports at Parkstone, near Poole. Extensive pottery works have been established for the manufacture of drain pipes, tiles, &c. The surface clay is converted into bricks, and machinery has been put up there which can make 14,000 bricks daily. About 200 persons are employed at the Parkstone Pottery Works.

It is stated that the project of uniting Lake Huron and Lake Ontario bids fair to be a reality. Able engineers have decided that the work is feasible, and that it will not cost more than 40,000,000 dollars.

The scarcity of teachers in Yorkshire duly qualified to give instruction in science in accordance with the regulations of the Department of Science and Art has led the council of the Yorkshire Board of Education to concert measures for the supply of the deficiency. One important step is the organisation of Schoolmasters' Science Classes, to meet on the afternoons of Saturday during the winter, for the study of special branches of science. The movement was brought under the notice of the schoolmasters in the Leeds district at a public meeting held on Saturday in the Civil Court of the Townhall, under the presidency of Sir Andrew Fairbairn, Mayor of Leeds. The first class will be opened in Leeds, on Saturday, October 3. Classes of a like character will be formed forthwith in Sheffield and Stockton-on-Tees. By providing a staff of men fully qualified to conduct evening science classes for adults the council of the Yorkshire Board hope to be able to bring instruction in science within the reach and means of the industrial population of the country.

The Government palace at Smyrna is to be rebuilt. It is in a good situation by the sea shore, and is close to a large and striking building, the Great Barrack, formerly the English hospital during the Crimean war. It is supposed the architect will be M. Rocca-Vitulis, a native of Smyrna. The old palace was a picturesque but tumble-down wooden building.

On Friday last the designs for the new law courts, which were deposited at the old Insolvent Debtors' Court, were removed by order of the Government to South Kensington Museum, for exhibition and for the purpose of study.

A new entrance has been opened in that part of Hyde Park which is set apart for equestrians on the south side of the carriage drives that run parallel to the Bayswater-road. The entrance, which is opposite the Edgware-road, allows the equestrians to enter the gallop without interfering with the carriage entrance at the Marble Arch in the vicinity.

Trade News.

TENDERS.

BERSLEM.—For additions to Messrs. T. and R. Boote's manufactory. Mr. R. Butler, surveyor, Burslem:—

Brindley and Critchlow	£1160
Blackhurst	1151
Bowden	1 34
Watkin (accepted)	1127

DALSTON.—For alterations and additions to Pownall-road Independent chapel. Mr. Henry Fuller, architect:—

Pritchard	£647
Staines and Son	579
Feast	535

ERDINGTON.—For the workhouse to be built for the Guardians of the Aston Union:—

Dover and Co.	£18,175 13 0
Cresswell and Sons	17,500 12 0
W. and J. Webb	17,166 11 0

COMPETITIONS.

INDIA.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

METROPOLITAN BOARD OF WORKS.—September 24.—For constructing and maintaining in repair certain intended brick sewers. J. Pollard, clerk, Spring gardens.

HIGHGATE.—September 30.—For the erection of an infirmary at Highgate. J. Moore, clerk, vestryhall, St. Pancras.

LEAVESDEN WOODSIDE (near Watford).—September 30.—For the erection of schools. J. Moore, clerk, vestry hall, St. Pancras.

WEST HAM UNION.—September 23.—For the erection of an apparatus capable of cooking for 800 inmates. F. E. Hilliary, clerk to the guardians, Leytonstone.

METROPOLITAN BOARD OF WORKS.—September 29.—For the erection of fire brigade stations at Amhurst-road, Hackney, and Upper Tooting. J. Pollard, clerk to the board, Spring Gardens.

STRATFORD.—September 23.—For the erection of a store in Maryland street. H. Ough, architect, 23, Charing Cross.

PETERBOROUGH.—September 26.—For the erection of a new Baptist Chapel. J. W. Chapman, architect, 14, Great Western-terrace, Westbourne Park, London W.

PADDINGTON.—For refitting certain stoves to the new wing of St. Mary's Hospital. J. G. Wilkinson, secretary.

THORPE, NEAR NORWICH.—September 26.—For the erection of an additional wing to the Norfolk Lunatic Asylum. F. J. Blake, clerk to the visitors, Norwich.

TAUNTON (Somerset).—September 30.—For building a shop, with house and offices. Messrs. Giles and Robinson, architects, 7, Furnival's Inn, W.C.

HEMEL HEMPSTEAD UNION.—September 23.—For the erection of new infirmaries at the union workhouse. C. E. Grover, clerk, Hemel Hempstead.

LINCOLN.—September 23.—For the erection of the new church of St. Swithin. J. Fowler, architect, Louth.

BICESTER (Oxon).—September 24.—For restoring, refitting, and making certain additions, &c., to the Parish Church at Stoke Lyne, near Bicester. Rev. C. D. Marsham, the Rectory, Caversfield, near Bicester, Oxfordshire.

GLATTON (Hunts.).—September 22.—For the restoration and reseating of Glatton Church, in the county of Huntingdon. James Ruddle, North street, Peterborough.

SLOUGH.—September 30.—For the erection of two villas in Windsor road. F. Charsley, Herschels, Slough.

PORT MADOC (North Wales).—October 5.—For the excavation and building of quay wall. G. Lea, 54, Chancery-lane, London.

EATON (NORWICH.)—For designs for new suburban church. Messrs. Hewitt and Capon, London and Norwich.

DERBY.—October 1.—For the erection of new hotel, &c., in Cornmarket and St. James-street. W. C. Watson, Company's offices, Wardwick, Derby.

WAR DEPARTMENT.—For raising the practice butt in Plumstead marshes. Capt. W. Mitchell, R.N., Royal Engineer office, Woolwich.

ST. PANCRAS (Middle-ex).—September 30.—For the erection of infirmary for this parish at Watford, Herts. F. Moore, clerk to Guardians.

ATHERSTONE.—September 23.—For construction of brick and earthenware sewers and manufacture of pipes, &c. W. Bishop, clerk to committee.

TUNBRIDGE WELLS LOCAL BOARD.—September 29.—For construction of outfall sewers, overflows, sewage tanks, &c. T. Elliott, clerk

WITHAM LOCAL BOARD OF HEALTH.—October 1.—For the construction of sewers and waterworks.—J. H. Blood, clerk.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

Samuel Keetch, Hornsey-road, Holloway, carpenter, September 25, at 12—Thomas Potterton, Balham hill, builder, September 24, at 1—Charles Saunders, Leytonstone, builder, September 29, at 11.

TO SURRENDER IN THE COUNTRY.

John Crossley, Burnley, painter, September 24, at 3—William Hampshire, Huddersfield, mason, September 28, at 10—James Johnson, Warrington, joiner, September 24, at 12—Richard Thomas, Perran-arworthal, Cornwall, surveyor, September 21, at 12—John Carver, Wellington, builder, September 25, at 11—Cornelius Cochrane, Manchester, joiner, September 30, at 12—William Davies, Allt-wen, Glamorganshire, plasterer, September 29, at 11—Griffith Evans, Newport, Monmouthshire, mechanical engineer, September 25, at 11—George Hanlon, Liverpool, civil engineer, September 29, at 11—Edward Hanlon, Liverpool, civil engineer, September 29, at 11—William Tyres, Nottingham, builder, September 29, at 11.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

October 22, C. Turner, Ann's-terrace, Camden-grove, Peckham, builder October 22, H. O'Connor, Battersea, contractor for railway works—October 8, J. Watson, Blagrove-road, Notting-hill, builder—October 15, G. Day, Kingsland-road, builder—October 12, W. Baker, Kingsland road and Russell road, Holloway, cement manufacturers—October 12, H. Edwards, Cardiff, builder—October 5, R. Robinson, Monks Coppenhall, joiner and builder—October 17, J. Jowling, Rose, builder—October 7, J. Marsh, Moorfields, Gloucestershire, carpenter and builder—October 6, G. Baker, Bristol, painter—October 8, D. B. Hamer, Rhayader, builder.

DIVIDENDS.

October 13, J. Potts, Adswood, near Stockport, brickmaker.

PARTNERSHIPS DISSOLVED.

Morton and Son, Toxteth Park, builders—Williams and Schofield, Montague-street, Bloomsbury, surveyors—Lee and Hibbard, Leeds, builder—Shaw and Emery, Burslem, builders—Bocock Brothers, Bradford, Yorkshire, contractors.

SCOTCH SEQUESTRATIONS.

John Inglis, Glasgow, builder, September 18, at 12.

THE BUILDING NEWS.

LONDON, FRIDAY, SEPTEMBER 25, 1868.

CITY SAUNTERINGS.

IT would be idle to assume that the disasters which have fallen upon the commercial world during the past few years have not greatly checked the progress of building. Where one building is erected in the City at present there were at least four in progress in 1865. There are, however, several works completed or approaching completion which are well worthy the attention of the student, and, to one who can use his eyes, the City at all times offers a field for improving observation. In the first place, there is diversity, and the progress of national art is better traced in a multitude of minor examples than in a huge representative one, as in the Houses of Parliament, the future Law Courts, or National Gallery. In the City, buildings worthy of notice are met with at almost every step. There is the graceful Grecian style, the palatial Palladian, and the gimcrack Gothic. In short, "no milliner can so fit his customers with gloves" as the student may be fitted with his favourite style of architecture anywhere between St. Paul's and Aldgate pump, though eastwards of that useful structure architecture decidedly wanes. The traveller can scarcely do better than take an omnibus to that *ultima Thule*, and, setting his face westwards, observe what is to be seen in Leadenhall-street. There is not much that is absolutely new, but there is a good deal that is nearly so. On the north side of the street will be seen the offices of the London and St. Katharine's Dock Company, a rich-looking but quiet building. The polish has gone off the grey granite, and the effect is better than at first, when the glitter was obtrusive. The carving on this façade is remarkably good—delicate without being finiking, and bold without being coarse. There are few buildings in the City which are ornamented with such excellent carving. Close by is the office of the world-renowned Peninsular and Oriental Company, a building of delicate details, though somewhat wanting in breadth. The treatment of the arcade of the first floor is not thoroughly satisfactory. It is most difficult to design a circular-headed window divided into two circular-headed lights; if it is well done the effect is good, but if absolute excellence is not attained positive ugliness is the inevitable result. We know of but two examples where excellence has been reached—in the Palazzo Strozzi and the Palazzo Ricciardi, at Florence. In company with the Peninsular and Oriental Company's building may be seen an old-fashioned overhanging house, No. 133, connected with old world courts of the famous Ship and Turtle. Of the building erected on the site of the East India House the less said the better; it is painfully mediocre. Leaving the building of the London and Lancashire Fire and Life Assurance, by Mr. Allom, with its excess of carving, the traveller should turn southwards down Gracechurch-street, bestowing a cursory glance on the City Offices' Company's building at the corner of Lombard-street, where he will see nothing to admire, though much to wonder at. A few steps will now bring him into Eastcheap, face to face with the important building now being completed for Messrs. Hills and Underwood, by Mr. Roumieu, Messrs. Browne and Robinson being the contractors. This building is, by all odds, the most striking the City can boast of. The style is Gothic, and there is no doubt whatever about it. It would be impossible to attribute it to any particular date or country. It is English Gothic of the middle of the nineteenth century, and not bad Gothic at that. It has a frontage of 46ft., a depth of 96ft., and a height of about 60ft.; the materials are red brick, with dressings of Tisbury stone, and the brickwork is much the more expensive. The hoods over the windows of the second story have a great, perhaps an excessive, projection, and, as the walls are very thick, deep shadows are obtained throughout. The hoods are sustained by eight little columns of Devonshire marble, which have already lost their polish. The roof is broken into gables, and is handsomely crested. A description of this building will not convey a fair idea of its merits; it must be seen. We are far from saying that it is perfect, or, indeed, any great way on the road to perfection, but it is an honest and earnest effort, and the pity is that Messrs. Hills and Underwood had so much money and Mr. Roumieu so little moderation. The staircase and halls are lined with a dado of tiles, bright and clear. The carving is of a very superior character, as may be seen in the boar's head in the spandrel over the central window, and elsewhere. The metal work of the gates, and, indeed, throughout the building, is very good. It is by Peard and Jackson, Holborn, from designs by Mr. Roumieu. The crane for lowering casks, &c., into the cellars is Sisterson's patent, a most compact and powerful affair worked by one man with an endless chain; it is a sort of telescope, with extraordinary capability for extension and change of direction. The gablet in the centre of the façade is a mistake. The construction is scientific and the workmanship very good. Altogether, this is a representative building. We think we perceive a *soupçon* of Bruges and a slight flavour of Rouen, and, moreover, we have our notions of timber construction and building in brick and stone, and do not care to see the principles mixed; but we should be glad to see three or four dozen buildings designed with as much care and carried out with as much skill as the warehouse of Messrs. Hills and Underwood, in Eastcheap.

From Eastcheap to Mark-lane, "*Non è lontano il tragetto*," as the wicked duke observes in the opera, and Mark Lane presents many improving spectacles. The comparatively ancient buildings, those erected seven or eight years ago, we do not propose to notice at present, but one by Mr. Aitchison, in the true Venetian style, close to the Corn Exchange, is deserving of more than a passing glance. No. 29 is in course of building. It promises well. No. 36 is an ambitious structure in the London-Venetian style, and must have cost a lot of money. It has a frontage of about 70ft., and is about 50ft. in height. It is four stories high, and consists of an arcade of seven arches. The architrave is supported by clustered columns of granite, with the usual carved caps, and the architraves are of red and grey Mansfield stone. The cornice is not all that a cornice might be, but in these narrow streets the architect is restricted; he is not allowed "verge enough" under penalty of an injunction, with the prospect of a motion to make the injunction perpetual. The interior of this building is satisfactory. The offices are light and cheerful. The ironwork of the staircase is of elegant design. The gates are a study, and the wrought-iron girders, which are visible in every direction, are craftily pierced in the web. The halls and staircase are lined to a height of five feet with tiles of good design, and the building generally is well worthy of a visit. The ironwork is by Handisyde, of Derby; the contractors are Messrs. Jackson and Shaw, and Mr. Edwin A. B. Crockett is the architect. There are some little attempts at coloured decoration in the iron caps to columns in the rooms of the ground floor which are not successful; but paint is cheap, and experiments in that line are neither difficult of execution nor exhausting to the mind.

From Mark-lane to Bishopsgate-street is no great distance, and Crosby Hall should be visited. With regard to this establishment it were well to bear in mind the inscription on the resting places for those who "fardels bear" in front of the Old Bailey and elsewhere—"Rest, but do not loiter," more particularly if you desire to see the Hop Exchange in the Borough. About a year ago we had occasion to speak of this building in terms the reverse of complimentary. We see no reason at present to modify one expression we then used. The building is a discredit to all concerned in it, and represents £60,000 diverted from the cause of true art into the *maelstrom* of bad taste. £60,000 for the building and a similar sum for the site is a good deal of money, and in its application ought to result in something better than the Hop Exchange, which was inaugurated on Monday, the 14th. It is impossible to criticise this building, but we may remark that the vestibule or lobby, which was commented upon in these pages last year, is now enclosed by temporary gates, which will shortly be replaced by iron of more or less elegant design. The fault of the vestibule consists in this—that it is over-decorated, and is neither indoors nor out. The gates are a step in the right direction. The hall is light and airy, and we have no reason to doubt but the offices opening into the balconies will be convenient, but, as far as elegance goes, the Hop Exchange is as near the zero of merit as a building well can be. It covers 1¼ acres, has 5½ acres of warehouse space, with an area of cellarage of 1¼ acres. The façade is 340ft. in length, and 100ft. in height. There are ten stories above the pavement. The Exchange proper is 80ft. long, 50ft. wide, and 124ft. high. We wish it had cost less, cheap as it is, and looked better. We have trespassed into the Borough, and sauntered out of the City, but there are in the City many other buildings possessing architectural merits which will call for notice sooner or later. It is plain that occasionally fault must be found. Indiscriminate praise is "censure in disguise." It is not easy to tell the student what he should do without exhorting him to avoid certain things, but in praise we hope to be ever hearty, and in censure ever considerate.

BRIDGE CENTREING.—II.

ONE of the principal advantages connected with the substitution of iron for stone in the erection of bridges was that the necessity for fixed centreing could be dispensed with provided circumstances rendered the adoption of such a course imperative. It would be hardly within the limits of possibility to build a stone arch without the support of centreing below. Brunel, the great engineer, succeeded in constructing a couple of semi-arches in brickwork springing from the same pier, so that they may be said to have balanced one another, but this must be looked upon more in the light of an experiment than an example to be imitated in actual construction. It was, no doubt, a very satisfactory demonstration of the strength of cement and hoop bond, but scarcely suitable as a model for engineers. Brunel had immense faith in the strength of cement, and that it was not unfounded is evidenced by the durability of the bridge he constructed at Maidenhead, for the Great Western line. This is a brick structure built on the skew in three arches with spans of nearly 130ft. When first constructed in ordinary mortar, it was discovered upon striking the centres that the arches would not stand; they were consequently re-turned in cement, and there has never since been any doubt of their stability. With regard to the subject of fixed centreing, the most important detail connected with its duties is that which is brought into notice at almost the expiration of its term of temporary service, when the time has arrived to "ease the centres," "décintrer," as continental engineers call it.

The description of bridge exercises a considerable influence upon the care and attention

that should be bestowed upon this operation, and we may here institute a comparison between an iron and a stone structure. The new Blackfriars and the old Waterloo bridges will answer admirably. Let us take the arches of the former as they are now, suspended as it were in mid air, not resting upon their beds, but supported at intervals only by the centreing underneath. The usual method of easing centres is to slacken the wedges upon which the uprights or some other portion of the framework is supported. There is another more elegant and scientific *modus operandi* which we shall allude to presently, and which has recently been practised in France. Now if we confine our attention to one of the iron arched ribs at Blackfriars, it is clear that, as it is one continuous mass of metal from springing to springing, and stiff enough to be proof against any lateral distortion, it requires to be lowered only at its two extremities. In other words it could be supported, when once the union of the separate subdivisions was accomplished, at those two points, and consequently the *décintrement* might theoretically be restricted to two points, also. One of the arches, in which a considerable waterway is left clear for the shipping, is virtually only supported by its two springings. A stone arch, on the other hand, demands not merely a more elaborate description of centreing, but a vast deal more of circumspection and care in the striking and easing of it. Were one end of an iron rib to be allowed to settle down on to its bearing before the other, there would be no harm done, but if one portion of a stone arch were to settle before the other, it would be a difficult operation to "reduce the dislocation" and restore the structure to its original form and conditions of stability. When the centres are struck beneath the arch every voussoir should settle uniformly and contemporaneously; the lowering should take place gradually, imperceptibly, and surely. It is not too much to assert that the whole of the previous labour, time, and expenditure incurred may be jeopardised by an unskilful and careless performance of this last duty. A glance at the soffit of an arch of either brickwork or masonry is sufficient to indicate the manner in which the centreing has been put up, maintained in its place during the turning of the arch, and removed when its services were no longer required.

In order to permit of the gradual and uniform descent of the centres, a method said to be borrowed from the Egyptians has frequently been employed, and was recently successfully applied in France. We do not mean to assert that the Egyptians used this plan for the purpose of bridge building, but that they were acquainted with the principle, and adapted it to the lowering into position of many of those gigantic monoliths and enormous masses of stone which so strongly characterised that period and style of architecture. The modern instance to which we allude is the *décintrement* of the large skew bridge of Lelles-sur-Cher, upon the line of railway from Tours to Vierzon. This operation was performed by means of small boxes filled with fine sand, and a French authority assures us that there is a remarkable example of the application of this principle under different circumstances in the ancient pyramid of Cheops, which is situated a few miles from Cairo, and has for ages existed in all the majesty of its solitary and imposing grandeur. A brief description of this instance of the antiquity of an ingenious engineering feature will not be without interest to our readers. In the very heart of the pyramidal erection is placed, in gloomy isolation, the mortuary chamber, the entrance to which is reached after traversing a long and narrow corridor equally sombre as the funeral vault into which it conducts the intrepid explorer. Within this inmost "penetralia," there lies a sarcophagus of syenite or Egyptian granite, supported upon a layer of exceedingly fine sand. Upon each side of this massive block are two apertures large enough to admit the hand. Nearly fifty centuries have elapsed since the sand was first submitted to the superincumbent pressure, but upon introducing the hand and abstracting it, the enormous stone can be observed to descend gently and perceptibly. The easing or striking of the centres of large bridges has occasionally been performed by this principle. Each upright of the centreing, or as many as may be considered necessary, is supported upon a small column of sand enclosed in a strong wrought-iron box, and the *décintrement* is effected by tapping the sand, so to speak, and allowing it to flow out at the bottom of the box. This operation being executed simultaneously with all the boxes forming the *points d'appui*, the centreing settles with all that uniformity and steadiness demanded by the nature of the circumstances.

It is often alleged that English engineers are too practical, and that, although the days of doing work by "rule of thumb" are gone never to return, yet there is some of the old leaven remaining. Possibly this statement may be to some extent correct, but if we err in the one extreme, our continental *confreres* are not altogether beyond suspicion of trespassing upon the other. If it were not that they had learned after some hard lessons to combine some of the rough and ready style of working that belongs to all our self-made engineers and contractors with their own more cognate and scientific system, we should still be in possession of a monopoly of railway and other engineering works on the continent. A railway cannot be either designed or constructed "by the book," and, provided due regard be had to theory, and none of its rules absolutely violated, precedent and practical knowledge will ever do more than algebra and the *calculus*. The example we have adduced is sufficient to point out that French engineers delight in *tours de force*; they prefer, if possible, accomplishing their purpose by an intricate, complicated, and needlessly scientific method, instead of executing it in the simplest and most common sense manner. An English engineer in the first instance regards a project in a practical point of view, and then calls in the aid of science if necessary to enable him to complete his designs and calculations. He makes the theory in one sense subservient to the practice; he uses the latter largely, the former sparingly.

DEVELOPMENTS OF NONCONFORMIST CHURCH ARCHITECTURE.

(CONCLUDING ARTICLE.)

HAVING noticed in previous papers the arrangement of the main feature—the auditorium—it remains to say a few words about certain adjuncts and details. The first of these which naturally suggests itself is the tower. It is the fashion just now to put some sort of a tower to every Nonconformist church, no matter how poverty stricken. In very many of these cases, and in very many Anglican churches too, it would be wiser to save this expense and use it in giving height and solidity to the rest of the building. A good church with no tower is better than a starved one with it. But, supposing that funds are sufficient, what is the purpose of a tower in the edifices now treated of, and what character would, therefore, be appropriate to it? The towers of Nonconformist churches generally are not bell-towers. *Why* they should not be is a different question, though until better bells than most modern ones can be afforded it is devoutly to be hoped that they may not be. If the quality of the bells were on a level with that of the architecture, some neighbourhoods would soon become uninhabitable. But there are other uses for a tower besides the one just named, the chief one being to call attention to the church at a distance, to indicate its position, perhaps even to make known its very existence. There are numbers of churches in the back streets of London quite unknown to nine-tenths of the people who pass near them daily, simply because they are destitute of towers. But a tower built as a signal or mark need not surely be copied from a bell-tower. The minaret of a mosque, or some of the southern Gothic turrets of similar character, would be a much more suggestive model. Height is what is wanted, not breadth of base. For the sake of economy, as well as for that of fitness, something different from the ordinary ecclesiastical model is to be desired. Something of the sort has, doubtless, been tried, but hitherto unsuccessfully. The overgrown pinnacle which so often does duty for tower and spire in a certain type of chapel seems like an attempt to realise this idea. Unhappy as the result is, it is worth noting as one effort after what is still not attained, a fitting tower for a Nonconformist church. A tower of this kind, since it exists mainly for the sake of being seen, should be a beautiful, or at least a picturesque object. Features of necessity or structural use have some apology for awkwardness; a chapel tower has none. Its beauty ought to be its own justification. Many ancient structures of the class have an almost shapeless massiveness—well fitted to their purpose, but absurd in a reduced copy when that purpose is wanting. The chapel tower should be the flower of the building rather than its main stem; its model the minaret rather than the belfry.

A little more variety in the *position* of the tower is an object very much to be desired. There is no reason why it should, perhaps in nine cases out of every ten, occupy the same invariable position at the side of the front gable. Monotony has really gone a little too far in this matter; and even a change for the worse, if that were possible, would almost be felt as a relief. This practice, which avails itself of the gallery staircase walls as a base, probably originated in motives of economy. Unnecessary outlay on such a feature was liable to be severely criticised; but, when so much of the height was practically needed, it was only a pardonable extravagance to carry the structure a little higher and make a tower of it. Besides the wearisome uniformity, however, which the system involves, it often makes the tower larger on plan than is at all desirable. Even in the existing type this is felt as a difficulty; witness the contracted, strangled-looking throat of the ordinary chapel turret just above the roof. So much for following architecture in a half-hearted spirit; the little economy at starting is just sufficient to spoil the effect of all subsequent outlay. But if the tower were intended from the first for a definite use, instead of being considered an ornament scarcely to be defended, some variety might be hoped for both in its position and its design. The gallery staircase would not have to stand as a kind of excuse for it, and, from its smaller size, too, the cost would, probably, after all, be no more than now.

The tower, then, being once made an independent feature and not a mere capping to the staircase, the latter might become an effective and characteristic adjunct. At present the custom is to hide it in the interior of the building, to disguise it as the fragment of an aisle, or to make it appear in other ways like anything but what it is. All this, of course, is part of the same system, that which tries to make a galleried church pass for an un-galleried one. To show the staircases would be to confess the truth. And yet in the few instances where they have been boldly exhibited, the result might almost have tempted chapel architects to lapse for a moment into naturalness and reality. Here, as elsewhere, the necessary arrangement of the building only needs thoughtfully working out to produce new and excellent forms; but the thought and labour are wanting, and what passes for architecture is the disguise of the actual facts into that shape which Nonconformists amusingly suppose to be the "correct" one.

The entrance lobby or vestibule is another feature which might be further developed

with great advantage. In a climate like ours it is almost a necessity. A small porch does not give the accommodation needed; and even the Classic portico, inappropriate as it is, is often more serviceable. Something differing from both, less open than a portico, and less cramped than an ordinary porch, seems to be what is required. Large lobbies of this kind are, indeed, common enough internally, but as an element in external design they are all but unknown. There are a multitude of other points which might be noticed, did space permit. Very much might be said on the general use of open roofs of a steep pitch, on the forms of ceiling sometimes substituted for them, on defective ventilation, and on the need of more facility for admitting air in hot weather, as well as on such matters of detail as the design of pulpits and gallery fronts. It is not, however, intended at present to follow the subject into these minutiæ, nor to take up the important questions of style and building materials. None of these items belong so specially to this class of buildings as do the questions of plan and arrangement, to which our remarks have chiefly been directed; but they will inevitably come to be reconsidered if any life and reality are ever infused into Nonconformist church architecture.

It is not, however, by Nonconformists only that the first principles of church design have still to be decided on. Their system is but one branch of a much wider one: the ideal type for their buildings is but one variety of the ideal type for Protestant worship generally. While all religious thought seems to be arranging itself round one of two centres—the Protestant or the Catholic—the system of free inquiry and the system of authority; when all minor divisions bid fair to be obliterated in these two great ones, it is plain that the first yet lacks that visible embodiment which the second long ago attained. The accessories of the one are complete, those of the other chaotic and fragmentary. A mediæval church, or even a good modern ritualistic one, is expressive of the creed which raised it. It is, at any rate, consistent throughout, everywhere suggestive of the same feelings, animated by the same spirit, fitted with the same perfection for the service to be conducted. How many Protestant churches are equally perfect, equally distinctive and characteristic? The best of them are still in a transitional state, with the germs of future growth half hidden by the dead remains of the past. It is vain to nurse any longer those forms from which life has departed; the best hope is to cultivate those which are rising from the soil. Protestantism has tried long enough to bend the Catholic type of church to its uses; the results all join to bid it evolve a type of its own.

SYMBOLISM.—II.

IT is clearly not sufficient that one thing be constituted the sign or emblem of another to render it a symbol of the higher and more instructive type. The algebraic signs —, +, =, are termed symbols of the ideas of reduction, addition, and equality respectively, and the Chinese alphabetic characters are symbols of words, or rather of the ideas which words express; but in these cases no natural correspondence, no conceivable resemblance, exists between the representing and the represented things. Such symbols are simply arbitrary. A nearer approach to the higher conception of a symbol was made *ex. gr.* in the Egyptian hieroglyphic of a bird with its beak in the water to represent "fishing," or two feet in apparent motion to represent "walking." When the Greeks made a trident to symbolise Poseidon, the god of the waters, they fixed upon an arbitrary sign; a bident, if it had the advantage of having been chosen, might have done quite as well, the suitableness not being in either case inherent, but the effect of *stet pro ratione voluntas*. But not so when the lion is put for courage, or the cornucopia for plenty. The destination here is not altogether arbitrary; it is justified in measure by the immediate and agreeable perception of harmony enjoyed by the mind, and what otherwise would appear a dead and unmeaning sign, compelled to do reluctant service, is welcomed and valued for its obvious appropriateness and expressiveness.

Symbols, then, are arbitrary or natural, conventional or rational, just as the accident of their first selection may have determined, although when once selected and having become customary and acknowledged, they all alike pass current as of equal value for their specific purpose and sphere. In the nature of the thing there is no reason why a lamb should not stand for youth or tenderness as well as for simplicity or "innocence;" or a sceptre represent royalty as well as be technically confined to the expression of "power" or "authority." But since, with a degree of arbitrariness as well as with a degree of reason, the latter objects have been coupled with the emblematic figures, and custom has established the usage, every purpose is answered. So in the alphabet, the letter *a* represents one variety of sound, *e* another, *i* a third, although in these forms themselves there is scarcely any conceivable certainty, no professed analogy, with the sounds for which they are equivalents.

Much explanation, owing to the greater or less degree of arbitrariness thus shown in symbolical selection, is required to school the mind into a perception of appropriateness, even where appropriateness does exist. Every Englishman, of course, knows that—

Britannia rules the waves,

and the Englishman enters therefore, without much effort, into the meaning of the trident-bearing figure resting on a disc or chariot wheel, and all apparently floating on the water, on our copper coinage. You have only to explain to him that the figure is a personification of Britannia or the English people, and that the trident denotes authority over the sea, to enable him to conceive the proud idea that he is part of that great power which sends forth the "mariners of England" and the "wooden walls of England"—now, alas! as taxpayers well know, no longer "wooden," but built of penetrable iron, before whose might all the navies of the world cower, and the fancy, with its flattering symbols, is never likely to be forgotten. But it is with greater difficulty, in spite of the measure of veiled appropriateness existing, that one accepts the crescent, or imperfect moon, as the symbol of Mahommedanism or the Turkish power. If intended to have any relation to progress, it is obvious that a crescent may suggest a waning as well as a growing moon, and in the former sense would be a faithful, though not flattering, emblem of the Turkish power in our days. But, in truth, this symbol, borrowed from the Greeks, was intended as a new moon, to indicate the progress towards greatness and complete fulness of Islam.

Between civil and religious symbolism there seems to be no distinction whatever, except what exists in the objects represented. The seen and known is indifferently used to suggest and explain the hidden, be the hidden of greater or less significance. The commonest things rise to medium or highest dignity as shadows, in proportion as their substances rise. A bundle of sticks in the fasces spoke of Roman authority; two pieces of wood in the Christian cross awaken associations of a far loftier and more sacred kind. A ship is commerce in England; but the early Christians saw in this emblem all that was stormy, precarious, and yet buoyant and progressive, in the fortune and character of the Church in those sore and trying times.

In the same manner, common things become exponents equally of material objects or of mental states. The Egyptian ideograph of the figure of a dog meant a real dog only, while that of a female bearing a tambourine expressed, not the thing or act visibly represented, but the mental state, "joy," implied in the act. But the pleasure imparted by emblematical representation increases in proportion as the object ascends and hidden meanings are revealed, and the humble instrument of instruction has reflected upon it a lustre in proportion as it brings to view the high and distant, the ideal, moral, and divine; and it is most pleasing of all when symbol and object meet in a variety of surprising and expository correspondencies which tempt to a belief that the outer world is but a covering of the inner, and that all things, when philsophically seen, are seen in doubles.

Symbolism, pursued in this direction, was carried to its highest pitch, and far beyond its legitimate sphere, in the great Swedish dreamer's system of "correspondencies." All things may, indeed, by fanciful effort, be conceived as having their counterparts or shadows. The variety of the universe is so exhaustless, and the seeking mind of man so fertile in invention, that all ideas and all spiritual beings may easily have assigned to them, by an uncurbed fancy, relations and congruities which have no real basis in nature, but are mere imaginations of the thinker. Swedenborg believed himself to have made the sublime discovery that this huge creation is hung together on the principle of "correspondencies," that all material things are but visible copies of things invisible. That such a theory of the universe is beautiful and attractive none can doubt; but all things beautiful to the imagination are not, therefore, real, as has been proved by the falling through of many theories of Utopia, besides that of Sir Thomas More. It is most likely true that—

Things are not what they seem,

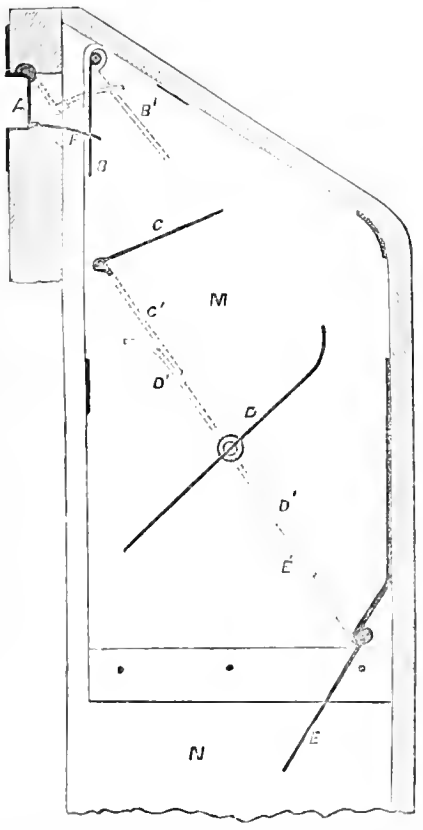
that they are deeper in significance, and fold in their draperies stranger mysteries than we have dreamed of, and a theory of correspondencies such as that alluded to, if anything but an illusion, would give the world a harmony and sanctity which would intensify the enthusiasm of nature's most wrapt admirers, and make not only poets, but, after a sort, worshippers of us all. It is a pity it is not true.

In this aspect of it the philosophy of symbols, though utterly impossible of wide belief, is more consoling in its very illusions than the dissecting-room philosophy, whereby some moderns, reviving old dreams, would show that mind is but a mode of action of matter. Mankind are, it is true, infinitely credulous, and this is a comfort to the new worshippers of muscles and nerves; but they are not half credulous enough to peruse, rosary in hand, the new missal, and believe that all intellectual and emotional phenomena are but fabrics woven by the material machine of the body. Have not, however, these very priests of the dissecting-room, with M. Comte at their head, their little partialities for a kind of symbolism also? They verily have, and their symbolism is full of little or great, indubitably ingenious disguises, to please the childish partiality for the invisible and supernatural, by some strange oversight on the part of the nerves and muscles, inherent in the constitution of man. They think it desirable to humour this partiality by means of a fine system of visible symbolic make-believes, representing another system of supposed, but absolutely unreal, so-called "spiritual" things. It is well to suppose that there is a God, and with grand ceremonial, in the finest temples you can provide, with music and incense and the other adjuncts, offer Him worship; but know ye at the same time that all these visible solemnities, all these words of adoration, all these bowings and reverences, all these signs and sounds, are but a vain show to please your childish years, until you have been educated into the perception that there is no god but "aggregate humanity," and that

"woman" is his prophet. On the whole, the world had not, before M. Comte's time of enlightenment, heard of a symbolic worship so interesting as this. Professor Bain has not yet developed his cultus. From the symbolism of ideas and of invisible things generally, to that of temples, and hence architecture, there is scarcely the distance of a step, and this distance we shall by and by retrace. In the meantime we must continue a little further our remarks on the less circumscribed applications of symbolism.

SHOVE'S PATENT LETTER-BOX.

IT has often been remarked that if one-tenth of the skill and ingenuity employed by thieves and burglars were directed towards the accomplishment of good instead of evil, we should be further advanced than we are in the useful application of the mechanical arts. The utmost endeavours of human invention have been unable to defy the efforts of the practised and skilful burglar. It is no wonder, therefore, that we witness continually new inventions designed to obviate and frustrate all felonious attempts. Among these is a patent letter-box by Mr. Shove, which is intended to prevent the possibility of any tampering with the contents. The insecurity of the ordinary letter-box and the facility with which the letters or other contents can be fraudulently abstracted are notorious. With the view of securing them against such attempts, Messrs Hart and Son have completed arrangements by virtue of which they have become the sole licencees and manufacturers of Shove's patent letter-box. Before describing in detail this ingenious little apparatus it may be stated that the principle upon which its construction is founded renders it an absolute impossibility for a letter or newspaper that has once been delivered to be extracted, except by the proper opening at the back of the box. It will be perceived from the accompanying illustration that Shove's patent



letter-box consists in reality of two divisions or compartments; the upper, M, and the lower, N, which are separated by a movable partition capable of being so adjusted as to open or close the communication between the upper and lower compartments according to circumstances. This movable partition is composed of three leaves, C D and E, comprising an upper, a central, and a lower one, and, in order to demonstrate the advantages belonging to the invention and the admirable and simple manner in which the mechanism acts, we will imagine the box attached to a door in the ordinary manner with letter-plate and everything complete. In this state the letter-plate is down, represented by the thick black line A, the opening or slit closed, and the communication between the upper and lower compartments of the box open. Directly a letter is to be delivered the plate is pushed back and the opening or slit revealed by the inner plate B and the letter-plate A assuming the position shown by the dotted lines at B', and now the ingenuity of the mechanism becomes apparent. The pushing back of the plate sets in motion small arms or levers which immediately act upon the three leaves C D and E composing the partition separating the two compartments of the box in the following manner. The central leaf D makes a quarter turn, the upper and lower C and E do the same in contrary directions, and then relative motions bring them close together, slightly overlapping each other, so that they form an inclined plane extending right across the box, and totally shutting off all communication between the upper and lower compartments. The new position is shown by the dotted line C' D' and E'. The letter is, therefore, received upon this inclined plane and remains there so long as the postman or the deliverer of it keeps the door plate pushed back, but directly he removes his hand and by so doing shuts the opening, the falling-to of the plate restores the small levers to their original position, the three leaves of the partition separate from one another and recover their original position shown by the black lines C D and E, leaving ample space for the letter to fall through into its final receptacle, namely the lower compartment N, where it remains until removed in the proper manner.

Upon an attempt being made to abstract the letter through the delivery opening the preventive action of the invention is at once apparent. No sooner is the plate pushed back in order to get at the centre of the box than all further fraudulent endeavours are at once frustrated, since, as has been already explained, the least motion imparted to the letter-plate immediately connects the leaves D C and E of the partition and places an impassable barrier between the upper compartment M, into which we may suppose a pair of clippers or other instrument to be introduced, and the lower N in which the letter is lying. In a word, it is an utter impossibility to reach the lower compartment so long as the slit is kept open by the pushing back of the letter-plate. The very act of moving the letter-plate so as to introduce through the delivery opening any instrument for the purpose of abstracting a letter or other contents of the box effectually frustrates all such attempts. The preventive arrangement is perfectly self-acting, and cannot be tampered with. This box can be readily substituted for any of the ordinary kind by simply removing the one and screwing or holding the other in its place after making a simple connection between the plates A and B. There is not the slightest necessity for the removal of the original door-plate, nor any especial fastenings of any kind required. The box is constructed entirely of zinc, a material well known for its non-oxidability, its clean appearance, lightness, and durable powers. It is handy and portable, and the mechanism is of so strong and simple a character that nothing short of wilful violence could put it out of order. A portion of the patent includes the addendum of an alarum, which would be set in motion by the movement of the letter-plate. This would also act as a signal, and might be found of use in many instances where the usual means of calling attention to the delivery of a letter were not available. Mechanically and practically considered, the real value of the apparatus lies in the arrangement of the shifting leaves, whereby the communication between the upper and lower compartments is cut off upon the least attempt being made to abstract the contents of the box.

THE COST OF AGRICULTURAL LABOURERS' COTTAGES.

MR. J. BAILEY DENTON, in a long letter to the *Daily News*, says much that is of interest to designers and builders of dwellings for the agricultural poor. After showing, upon economic grounds, that it is the real, if not the apparent interest of landowners, to provide dwellings for agricultural labourers, in the same manner as manufacturers provide dwellings for their operatives, he asks why we should not ascertain and unhesitatingly state what the real cost of cottages is, and why we should attempt by misrepresentation to make each other believe that cottages cost less than they really do It is clearly possible to ascertain with the greatest precision what cottages of different accommodation will cost under specific circumstances, and it is an illusion to declare that the local and attendant circumstances are so various that a correct representation cannot be made. Instead of determining the exact space and accommodation which each class of cottage should contain, and fixing the degree of substantiality requisite in each case, we seem to have been endeavouring for the last twenty years to obtain "cheap cottages," without any basis for calculation whatever. Cottages should not always be of one accommodation, as we are now disposed to build them, and if those with two bedrooms were mixed in due proportion with others of three bedrooms each, we should not only spend less money, but we should supply that which is equally wanted. Again, the space allowed in the model lodging-house is about 550 cubic feet per person, and if we adopt these figures as some guide to the cubical contents required in each class of cottage, we should clear the way of much misunderstanding. Supposing the height of the lower rooms to be, from floor to ceiling, 8ft., and that of the upper rooms 7ft. 6in., and that the living room should contain 1,200ft., the parents' bedroom 900ft., and the boys' and girls' room 650ft. each, while the scullery, pantry, and passages take in the aggregate 1,000ft. more, we then arrive at the space and dimensions applicable to each class of cottage. With these figures to regulate designs, it is not in the power of any architect, by any twisting and changing of the internal arrangements, so to vary them as to reduce the cost £10 per cottage in each class—assuming that the materials, degree of substantiality, and amount of internal accommodation are the same. Such is the conclusion arrived at from the study of the numerous prize designs with which the country has been favoured, and if Mr. Webster's recently-appointed committee of the British Association would carefully ascertain what has been done and actually paid where cottages have been built under the supervision of the Inclosure Commission, as well as what has been done by landowners independently, a great national advantage would be gained by the examples that would be afforded. It will be absolutely necessary, however, that persons competent to dissect details and arrive at facts and figures in a practical shape should be the examiners, and surely all architects whose plans have been used and are considered to be most economical would be willing that they should be submitted to such an ordeal.

Very striking results have followed the giving of prizes by our principal agricultural societies. It has been invariably assumed by the prize-givers that three-bedroomed cottages can be built for £100 each, and it has been a condition that the designs should be prepared accordingly. Directly, however, that the successful plans have been put to the test of contract, they have been found never to cost less than £130 each, and then under favourable circumstances only. The most approved plans for three-bedroomed cottages have in certain cases reached £175 each, where the prices of materials and labour were high, and where everything has been paid for except the land upon which they have been erected. Can we wonder that landowners, misled by pretensions of which this is an example, should hesitate to provide dwellings for the poor? In 1864 the Society of Arts offered prizes for designs of rural labourers' cottages, and 134 architects competed. Mr. C. F. Hayward (member of the Council of British Architects), Mr. John Clutton (President of the Institute of Surveyors), and Mr. George Dines (the well-known builder) were appointed to examine them. Their report closed with these words:—

> In fine, we may observe that, although good cottages may possibly be erected under favourable circumstances in some parts of England for a lower sum, we consider the probable average cost of a pair of cottages built with the conveniences we have enumerated, would be about £280 to £300, and that the attempt to erect them at any considerable reduction upon the amount must result in some inferior kinds of buildings discreditable to the owner, and wanting in much of the necessary accommodation for a labourer and his family.

There is no doubt, continues Mr. Denton, that this quotation represents the facts of the case accurately, and that wherever three-bedroomed cottages cost less than £280 the pair the reduction arises from circumstances which exclude them from general comparison.

It has often been stated, by men whose words make a deep impression upon the public, that

cottages are at the present moment being built on certain estates at £200 a pair. Having investigated some of the instances spoken of, Mr. Denton gives a few particulars. In one case he found that the bricks of which the cottages were built had been supplied by the owner of the estate at 18s. a thousand, the cost price, while he (the owner) was selling the same article to his neighbours at 28s. Gravel was allowed from the estate for concrete, and sand for mortar, without any charge. The haulage of the whole of the materials was done by the tenant of the farm to which the cottages were to be attached. This haulage of materials is worth from £20 to £30 per pair, according to circumstances; and thus there was upwards of £50 accounted for directly, which under ordinary circumstances would have to be added to the cost. In other cases it has been found that not only have the materials been chiefly supplied from the property, but the estate carpenter and mason have been employed to build, in which case the contractor's profit has been saved as well as the interest on money which a builder paying his men weekly, and only receiving payment on completion, looks to recover. Under such conditions a saving would be effected of from £30 to £40 on each pair of cottages, but inasmuch as comparatively few landowners have their own carpenters and masons, all fair comparison fails. Again, in the essential requirements of water and drainage, one landowner will be very particular in providing them, while another avoids them. In the provision, too, of sinks, coppers, ovens, cupboards, shelves, grates, and other minor items of accommodation, the greatest difference prevails. Mr. Denton says that he has said sufficient to show that a difference of at least £100 per pair of cottages may be accounted for in the way in which the work is carried out, and the amount of accommodation furnished. The cottages now being erected by the Earl of Leicester on the Holkham estate have cost from £210 to £230 per pair. Lord Leicester provides all materials, including doors, windows, and frames ready for fixing, the additional labour only being done by local tradesmen, by contract, under the supervision of his lordship's resident clerk of the works. Thus the trader's profit is saved on the materials and the labour incident to their preparation. The price named does not include haulage, which is done by the tenant of the farm upon which the cottages are built.

In conclusion, Mr. Denton expresses his conviction that the stereotyped form of cottage-building (*i.e.*, with three bedrooms upstairs, with living room and scullery below, and the necessary outbuildings in addition) must be departed from, and that we must, in certain cases, have one bedroom on the ground floor, as adopted by Captain Dashwood, and in others one larger living room, with the scullery as an outbuilding. Moreover, if we are in any sensible degree to reduce the cost of cottage building, it must be by the use of materials different to those that have hitherto been adopted. The use of home grown timber steeped in lime, and thereby made as durable as Baltic deal, is one object well worthy of consideration. The same may be said of concrete in the various forms in which it has been recommended.

THE SEWERS AND CESSPOOLS OF BRIGHTON.

WHEREVER noxious matter of any kind is allowed to accumulate, however salubrious may be the locality, the health of the inhabitants must suffer. The sewage of Brighton, a town of 80,000 or 100,000 inhabitants, is only partially carried away by sewers, a great portion being stored up in those hotbeds of disease, cesspools. Thus many who may go to Brighton (or other places similar in sanitary or non-sanitary arrangements) in search of health, may possibly return with the seeds of disease implanted within them, although utterly unconscious of the fact.

The suburbs of Hove and Cliftonville are not governed by the Brighton municipality, and, from want of unity among the powers that be, it has been found impossible (says the *Lancet*) to adopt a thoroughly comprehensive system for the drainage of the district and the utilisation of the sewage on the land. As it is, the sewage is turned by no less than six outlets into the sea. This fact must damage the "bathing" reputation of the town, as compared with Hastings or Eastbourne, where such an arrangement has been obviated at a vast expense. Immense volumes of dark and stinking sewage are poured out in proximity to the bathing machines, and during the recent hot weather the stench was considerable. The course of the currents is from various causes very capricious, and no dependence can be placed on the sewage being carried out to sea. Sometimes it is driven almost directly upon the shore. The proprietors of Brills' Baths have expended £10,000 in erecting a pumping station at Hove, to supply baths in King's road. This expense was necessitated by the contamination of the water at the latter point. In the absence of an intercepting scheme, which the *Lancet* Sanitary Commissioners would prefer to anything else, they recommend a prolongation of the outfall pipe and the placing of a cowl over the extremity, in order that the sewage may be more widely diffused. At present there are about 14,000 houses in Brighton, of which less than 4,000 are drained into the present sewers. There are probably between forty and fifty miles of streets, but only twelve miles of sewers are yet in operation, so that a much greater quantity of sewage will eventually find its way into the sea. A contract is now being carried on for thirteen miles of sewers, which will drain 6,000 more houses. There is still a lingering affection for the old cesspool system. Nearly every house has its own receptacle, and many more houses have two than none at all. At a low estimate 10,000 cesspools are now in operation in the town, most of them holding from two to three waggonloads of filth, and some containing more than twice this amount. It usually takes two men two, and in some instances three, nights to empty them. It may be estimated that eight or ten are opened every night. The frequency of this operation depends on the nature of the soil and the construction of the cesspool. There are four kinds: first, those made in what is called Coombe rock, which is a species of chalky marl interspersed with boulders, probably brought down from the shore by glacial action. This substance is quite impervious to water. Cesspools made therein are speedily filled up with very liquid matter, and easily run over. They require to be often emptied, and the farmers grumble because the contents are scarcely worth the trouble of cartage. Beneath this most peculiar deposit, which reaches at some points to a depth of 70ft, and extends for a considerable distance both in the eastern and western portions of the town, there is a continuation of the shingle of the coast, composed of rough stones and fine sand, with the remains of bones and curiously burnt bricks, which must have been made by man millions of years ago. Very many cesspools communicate with this, and as it is capable of receiving almost any amount of solid as well as liquid matter, these cesspools may go for fifty years without being opened. In the northern portions of the town the cesspools are made in chalk, and in many cases one above the other. When first made they absorb a considerable amount of solid as well as liquid matter, and they go for several years without being cleansed. But as the pores of the chalk become closed up, the interval between cleaning out becomes less and less, until at length they require to be opened almost every year. Lastly, very many wells have been closed for drinking purposes by order of the authorities, and have been converted into common cesspools. A most experienced person has never known one of them stopped up. The water-courses in the chalk are immense, and will carry off any amount of solid matter. But the so called springs appear in wells and on the beach, and are, in some instances, the source from which drinking water is derived. In the cesspool districts, disease assumes a peculiarly asthenic form, and nervous depression and neuralgic affections are very marked. These do not necessarily increase mortality, but they destroy the advantages which the invalid is entitled to expect at such an admirable spot. The Brighton authorities, hitherto too reliant on the reputation of their town, must bestir themselves in sanitary matters if they wish to retain public approbation.

THE FIVE ORDERS AND THE THREE ORDERS, AND THE ORIGIN OF FREEMASONRY.

AN interesting discussion on this topic has been going on recently in the *Freemasons' Magazine*. It arose from "Pictus," a writer in that publication, speaking of the ignorance, both of Freemasonry and architecture, sometimes displayed by some of the craft. It is absurd, he said, to hear the "five" orders spoken of as existing at the time of the building of Solomon's Temple. In reply to this, a correspondent said that if "Pictus" would look into Josephus, he would find that Solomon built his house supported by "quadrangular pillars," but "the roof was according to the Corinthian Order." This drew forth another correspondent, "Not for Joseph," who asked which Josephus was referred to as an authority that the Corinthian order was employed in Solomon's Temple—Josephus the historian or Josephus Miller? Both, he says, are equally good authorities on such a point.

"Pictus" again comes to the front, and argues for the correctness of his former assertion that it was absurd to speak about the *Five* Orders as having existed in Solomon's time (about 1,000 B.C.). Solomon, he says, was undoubtedly acquainted with the style of architecture in use among the Greeks; but the Greeks only used *Three* Orders—viz., Doric, Ionic, and Corinthian. It was not until long after the foundation of Rome (752 B.C.) that the Romans made the innovation of the Five Orders. Consequently Solomon could not know anything about what was not invented until several centuries after his death. "Pictus" trusts that his Masonic brethren will see the necessity of making a distinction between the Three Grecian Orders and the Five Roman Orders, when, the chronology of architecture being better understood, we shall have no more allusions, at least, to the Tuscan and Composite in connection with Solomon. "Pictus" further says that he had no intention of finding fault with or disputing the propriety of speaking about the co-existence of Solomon and the *Three* Grecian Orders, yet, notwithstanding the quotation from Josephus, he is not aware that even the Grecian Corinthian was in existence so early as Solomon. It is questionable if Josephus could have furnished any proof that Solomon really built his house "according to the Corinthian Order." Can any Grecian specimen of Corinthian, erected 1,000 years B.C., be indicated? "Pictus" thus concludes:—"There is (I hope I will not be misunderstood) in a Masonic point of view too much stress laid upon the Temple of Solomon. As a building it was undoubtedly a fine one, yet we may believe that there were other buildings erected about that time as good specimens of architecture as it was. It was not built *by* those whom it was built *for*. It is the religious ideas fixed in our minds, connected with Solomon's Temple, that give it its greatest interest in our eyes. I am not one of the believers in the popularly-understood connection believed to exist between Solomon's Temple and modern Freemasonry. I go in with the idea of the origin of Freemasonry being with the building fraternities of the middle ages. It is easy to conceive that many allusions would be made to, and illustrations drawn from, the building of Solomon's Temple, as well as other matters mentioned in the Bible, to excite and stimulate the brethren. Such scriptural allusions and quotations were customary with writers of the eleventh and twelfth centuries; thereafter, what was merely used in illustration came ultimately in process of time to be considered as fact. Yet while I support the idea of the Freemasons being the direct descendants or representatives of the middle ages, yet, in a sense, as masons, these building fraternities were on their part the descendants of the architectural fathers of pre-Christian times."

BUILDERS' BENEVOLENT INSTITUTION.

THE twenty-first annual report of this institution has just been published. Four additional pensioners have been placed on the funds within the last twelve months, the total number now being forty-eight—twenty-four men and twenty-four women. A satisfactory addition has been made to the funded stock: £1,525 19s. 3d. having been purchased for the relief fund, and £107 8s. 6d. for the building fund. The amount now invested is £11,322 19s. 4d. stock for the relief fund, and £2,939 19s 9d. for the building fund, being a total of £14,272 19s. 1d. stock three per cent. Consols. The directors, in thanking the late president, W. R. Rogers, Esq., especially allude to the good service he did to the institution by having obtained the large donation of £100 each from ten firms. They also, in thanking all their friends and supporters, ask them to renew their efforts so as to enable them still further to aid their unfortunate and deserving brethren. George F. Trollope, Esq., has kindly consented to act as President of the Institution for the ensuing year.

ST. MARY'S CHURCH, LICHFIELD.

THE erection of one of the most fitting of the many visible memorials of the late Bishop Lonsdale was formally commenced at Lichfield on July 30. The Rev. Canon Lonsdale, younger son of the late beloved bishop, succeeded to the living, and the necessity for rebuilding the church as a matter of safety as well as of taste and convenience led to the determination to erect a new building which should harmonise with the beautiful tower and spire in memory of the late bishop. The estimated cost is £8,000, and towards this the family of the late diocesan contributed £4,000, and the rest has been subscribed with the exception of about £1,000. When the tower and spire were erected Mr. Street prepared plans for a new church, but it was determined to invite competition for the design, and the result was that the plans of Mr. James Fowler, architect, of Louth, in Lincolnshire, were selected. The new church will consist of a nave 70ft. long with north and south aisles, and a chancel 30ft. long, and will accommodate 900 persons. It will be built of stone polished inside and out. The east window will be very large and elegant, and there will be six three-light windows on each side, and a four-light window at the east end of each of the aisles. The principal entrance will be on the north side, where near the tower there will be a very handsome doorway with deeply recessed and moulded arch, and carved capitals. There is a good deal of carving in the design, which includes a handsome reredos with columns of Devonshire marble, massive carved oak stalls, and altar rail in the chancel. On the south side of the chancel there will be an organ chamber and vestry, and on the north side, over the family vault, a chapel for the Dyott family. The contract has been taken by Messrs. Critchlow and Ward, builders, of Uttoxeter.

ST. SWITHIN'S, LINCOLN.

THE parish church of St. Swithin was at one time the largest and handsomest in Lincoln. It consisted of a nave with north and south aisles and chancel. The tower, containing a peal of bells, stood at the west end of the nave, and was remarkable for its good proportions. This building continued in good repair until 1644, when it was destroyed by fire. The ruin was left standing for some years, until the tower was considered unsafe from the weight of the bells it held, and was consequently pulled down and the bells sold.

In the Bodleian Library at Oxford there is a sketch by Buck of the ruin in the year 1720, which shows the remains of the south side of the nave and a handsome east window; it appears, too, from this sketch that the parishioners had roofed in a portion of the south aisle for the purposes of Divine service.

The present little church was completed in 1801, when the population of the parish numbered only 940. From that time the parish has been gradually increasing in importance until it has become by far the most populous in the city and now contains upwards of 7,000 persons, and the only church accommodation for this large number is the little building above mentioned, which is estimated to seat about 270 persons.

At various times during the last seven years attempts have been made to build a large new church, but all these attempts proved unsuccessful, until the present incumbent (the Rev. G. H. Pratt) commenced the work in earnest, shortly after his appointment to the living. He has been so far successful as to obtain a most valuable site adjoining the present churchyard and opening into the widest and most commanding street in the city. A very effective design has been supplied by Mr. Fowler, of Louth, who won the competition against ten competitors. The work is to be carried out in three separate contracts:—1. The nave and aisles. 2. The chancel and vestry. 3. The tower and spire. The whole is estimated to cost from £7,500 to £8,000.

RESIDENCE AT BAGSHOT, SURREY.

ON another page will be found an illustration of a residence recently erected on the estate of Sir George P. Lee, Knight, near Bagshot, Surrey. It has been the endeavour of the architects to treat it in the spirit of the English cottage style, combining simplicity and economy as chief recommendations. It contains three reception rooms, kitchen, butler's pantry, housekeeper's room, and other offices on the ground floor, with eight bed and dressing rooms. It is situate on sloping ground, commanding a magnificent view of Ascot, backed by fir and pine trees, forming a pleasing contrast in colour.

A few points in the construction may perhaps be of interest. The external arches are formed with perforated bricks laid in cement and placed on end, forming level soffits, thus saving centreing skewbacks and ganging to arches; the upper portion of gables projecting on corbels and formed of 9in. brick nogg and fir framed timber, stained and varnished, with entrance porch of open timber framed. No stone has been used, except for sills. The staircase and other internal fittings are in character with the exterior. Terraces will be formed to reach the garden, which is laid out with ornamental waters, &c. The roofs are covered with the Broomhall patent tiles. Stables in character with the house are now erecting. Mr. Roberts, of Islington, was the builder, who completed the work under contract for £1,720. The architects were Messrs. Walford, Donkin, and Co., 3, Queen's-square.

MURAL PAINTINGS AT WEST SOMERTON CHURCH.

THE discovery of the Fairford windows, though much more valuable, is scarcely more interesting than a discovery recently made at West Somerton Church, near Great Yarmouth, of some fine mural paintings. Mr. John L'Estrange, on the visit of the Norfolk Archæological Society to the church, gave an interesting account of these wall-paintings. It appears that in constructing a ventilator in the south wall of the nave traces of colour were detected, and Mr. J. T. Bottle, of Yarmouth, having heard this, obtained permission to clear off the numerous coats of whitewash. He was rewarded by finding that the whole space between two of the Early English windows of the nave, in length about 12ft., was occupied by an early painting representing "The Son of Man coming in the clouds of heaven with power and great glory." Unfortunately, the central portion of the upper part of the painting was irretrievably lost by the rebuilding of that portion of the wall some time since, and the plaster at the lower right hand corner is much decayed. Our Lord was evidently represented seated, with the globe beneath his feet, upon a rainbow, the lower portion of which is still left, but of the figure nothing but the bare feet remain. On either side of our Lord is a seraphim, presenting to him a kneeling female, the one on the right being the Virgin Mary. Lower down are two angels, habited in albes and wearing crowns, trumpeting the dead to judgment. At the bottom are eleven nude figures in various attitudes, amongst them being a king and queen, ecclesiastics, and two knights, whose acutely-pointed bassinets, together with the broad, bold style of drawing, indicate the reign of Edward III. as the date of the painting. The treatment of the subject corresponds with that of other mediæval representations of our Lord's second coming. On the north wall of the nave, opposite this painting, is a smaller painting, enclosed within a decorated border, of the Resurrection. This is considerably faded, but the figure of the Saviour stepping out of the sepulchre is tolerably distinct. It is confidently anticipated that the whole of the walls are covered with such paintings, but for the present operations are suspended for want of funds.

ANTI-SMOKY CHIMNEY STOVE.

MR. THOMAS NASH, jun., of Great Dover-street, Borough, the well-known inventor and manufacturer of the copper-bound painters' brushes, has recently patented certain improvements in domestic stoves and grates, their object being the promotion of more perfect combustion and the prevention of that too prevalent evil, a smoky chimney, as it is commonly termed. Mr. Nash provides the back of the stove or grate with a hot air chamber—that is, behind the grate-back he has a hollow space or chamber, the air in which becomes heated by conduction from the back of the stove or grate, when the back gets heated by the action of the ignited fuel therein. The aperture for the passage of the smoke or products of combustion is not, as in ordinary stoves or grates, a mere opening, allowing such smoke or products to pass directly to and up the chimney, but has a sort of hood or deflector, which brings the smoke or products of combustion within the action of the rarefaction of the air in the hot air chamber, and by the power of the upward current thus created ensures the ascent of the smoke or products of combustion, downward currents being opposed by the rarefied air thus generated in the lower part of the chimney, in the hot air chamber, and in the fireplace, as well as by the hood or deflector, preventing any sudden downward gust passing direct on to the ignited fuel, but causing it to be brought within the influence of the heated air in the hot air chamber, and thereby destroyed.

THE DEWSBURY NEW WATER-WORKS.

AT the present time several extensive contracts are being executed at the Waterworks for the United Water Boards of Dewsbury, Heckmondwike, and Batley. The works are situate at and near to Dunford Bridge, on the Yorkshire and Derbyshire moors. The contracts are in the hands of Mr. Nowell and Mr. Briers, who are executing the works, under the supervision of Mr. Bateman, of London. The operations comprise the Stamcliffe reservoir and the Wimbledon reservoir. At the latter place the works are being carried on on a large scale. The difficulties which have had to be encountered have been rather formidable. A dislocation or fault, which crosses the valley at the point where the puddle wall of the embankment was formerly fixed, rendered it exceedingly difficult to obtain a good foundation. This has now been overcome, and a good foundation has been found for a considerable distance across the valley. The puddling has been commenced at a depth of 30ft. below the bank, and it is believed that the work will be made secure. It is proposed to line the trench at the bottom and on the sides with concrete, so as to prevent any leakage. A large discharge tunnel, in connection with the reservoir, has been successfully driven through, and is now being lined with stone. In the embankment about 18,000 cubic yards of earthwork have been deposited.

PROVISION FOR THE SICK AND INSANE POOR OF LONDON.

IN June, 1867, an order was made by the Poor Law Board combining the unions and parishes of London into an asylum district for insane, fever, and smallpox cases, and the Metropolitan District Asylum Board was called into existence. By this combination great benefit must result to the sick poor. Spacious, well-constructed, and pleasantly situated infirmaries or hospitals will be an agreeable transformation from the dingy and pestiferous apartments in some of our metropolitan workhouses yclept "infirmaries," and the sad condition of which the *Lancet* Sanitary Commissioners did so much to expose. The Metropolitan Asylum Board bids fair to effect this transformation. Two asylums for the insane, each to accommodate 1,500 patients, are to be erected—one at Leavesden, near Watford, on the north, and the other at Caterham, near Croydon, on the south side of the Thames. Three asylums are to be erected for fever and smallpox patients—one for the north-western, another for the north-eastern, and the third for the southern district. The site for the north-western asylum is at Hampstead, for the north-eastern at Homerton, and for the southern at Stockwell. Great opposition has been raised by the inhabitants of Stockwell and Hampstead to the erection of such buildings in their neighbourhoods from fear of contagion, but the same opposition was raised some years ago by the Islingtonians to the erection of the London Fever Hospital in the Liverpool road. The hospital, however, was erected, and the population of Islington has not been decimated by fever, as was prognosticated.

In addition to these works, seventeen parishes and unions have been required to provide infirmaries on sites detached from their workhouses. Pending the completion of such arrangements many boards of guardians have provided temporary buildings. At Camberwell, Nazareth House, formerly a nunnery, has been taken as an auxiliary workhouse, and Price's Candle Factory, in Wandsworth-road, has been hired by the Lambeth guardians. At Islington and Kensington temporary iron buildings have been erected.

CATHEDRAL ORGANS.

IN spite of the cleverness of men of genius it must be confessed with some shame that a good deal of what is good and capital in this world, especially in art, has been the result of accident—pure accident, and nothing else. This was the case of the organ in Westminster Abbey, and in most, if not all, of the great cathedrals, including even St. Paul's. It was never originally intended, or for a moment contemplated, to put the organ in the middle of a great church like the Abbey, or York Minster, or St. Paul's. The screens or lofts on which they stand, or rather did stand, before the "Restoration Period," were simply, as everyone knows, for the purpose of shutting in from the outer congregation the "sanctuary," or place of sacrifice; though the word *sanctuary* is not quite an orthodox word, it is so expressive that it will well serve our present purpose. If the reader will, therefore, for a moment follow us into this curious and now so important subject, he will see the amount of mischief that is going on in so many of our cathedrals, confining ourselves to Westminster for the present, with an occasional allusion to other churches. First, then, it must be borne in mind that, under the old religious *régime*, such a church as Westminster Abbey was quite complete had it been confined to the simple "sanctuary" only—*i.e.*, the space included between the stalls, on either side, the screens and monuments, and east and west by the two screens, the altar screen, and the organ screen or rood-loft. This was the church or temple, the place alike of sacrifice and of those who assisted at it, while the worshippers might have been outside this sanctuary or central church altogether, under a grove of trees, without destroying the idea of the church or the purpose for which it was built. It was a simple matter of convenience to surround this nucleus or central sanctuary with nave, and aisles, and transepts, and eastern chapels, for with the idea of a *sacrifice*—and it all centres in this, and the Abbey is unintelligible without it—it was not necessary that the assembled worshippers should *see*, or even *hear*, what was going on; their mere presence near was enough, their duties and prayers were their own, and distinct from those going on in the central church or sanctuary. The surrounding nave and aisles placed them under the same roof. Thus, the whole sanctuary was consistently screened in by the two screens, the altar screen and organ screen, and stalls on either side, so that the organ screen, with which we are now concerned, is a kind of accident, and its position in the centre of the church wholly *accidental*. Now, in this our day all this is at an end; the very idea of sacrifice is over, and there is consequently no meaning whatever in the surrounding screens—they enclose nothing. This is a very curious subject indeed, for it shows how progressive enlightenment changes all things, and makes that now absurd which in past generations was all-absorbing and sanctified. Would you pull down the screens, stalls, and all else, says the reader here, and make a clean sweep of it for enlightenment sake? I reply no. I would keep all as it is—if for no other reason as a record and remembrance of the past; and, more than all, I would, had I been architect custode of the Abbey (or St. Paul's) have blessed my stars that so fortunate and happy and superstitious an accident had befallen the place as the putting of the organ screen where it is—viz., right in the middle of the church; for if all the power of human ingenuity possible had been brought to bear upon the question, "where to put an organ?" in a cathedral, so as to get the utmost power of sound out of it, nothing better could have been thought of or imagined, for it is free and open on all sides, and the four enclosing walls of the church would seem almost to have been built round it, and for it, and for nothing else. But for this to be thoroughly effective the instrument must stand in the middle of this space, right under the roof and away from the nave lateral arches, so that the sound may rise clear to the roof and travel east and west without impediment, as the sound of a musical box in the middle of an empty drawer. Your correspondent of last week remarks on the roll of the sound through the Abbey. It does this now of course, but not as it did before the stupid alteration took place, because there is no west wall reflexion, and the sound is shut in at the top of the pipes; but even this effect, pretty as it is, is as nothing to what it would be if the whole Abbey and Henry VII.'s Chapel were altogether empty and bare of furniture. There must always be something lost. If the cathedral were empty, then the sound would be at a maximum, but it would certainly lose something in architectural effect by being perfectly bare, and could hardly be utilised, so that something of *sound* effect must be sacrified. The place, therefore, of the organ loft or sanctuary screen in a cathedral church, and consequently of the organ on it, is as near as can be perfect; it could not be better or be improved. What a pity to miss all this! But it is not all. It may surprise many to be told that the whole series of pipes they see on the two fronts and four sides of this Abbey organ, and the pipes of the choir organ, are *shams*; they are not musical metal pipes, but wooden cylinders, to imitate pipes, and merely form a bad screen or case round the real instrument. The organ case proper is as bad as it can be, and the whole arrangement of the organ or rather organs would seem to be almost diabolical in foolishness of arrangement, and in certainty of failure. The "pedal organ" lies on the floor of the loft, so that the sound from its pipes blows on to the screen parapet, instead of up into the vaulted roof. Mark well, this is the *pedal* organ, that one of all which does the most emphatic work, and, to say truth, might sometimes be made to do more. The "swell organ," that most beautiful and happy of material musical thoughts, is, as I said before, destroyed, as far as it can be, and is surrounded by the aforesaid painted *shams* and with a close hoarding behind it, perhaps to deaden things a little, of which there is but small need here; and the "quoir organ"—and here is a hint for the organ builders—is right in front and between the two large ones, the organist sitting and playing between the four—*i.e.*, great organ, swell, pedal organ, on the floor, and the quoir organ in front. Now my argument is, "to open out the organ," but, if I wanted to deaden anything, and put it away out of sight—nay, out of hearing almost—it would have been this very quoir organ now so conspicuous; and for this simple reason, that if the singers be good and keep together, the instrumental accompaniment cannot be too low, except in emphatic and f. and f. f. passages; so that if I had to rebuild this Westminster organ, I would put the quoir organ in the middle of it, so that the sound of it should be low and distant. And here another loss comes to mind, which some few may perhaps recollect—the strange, almost weird effect of a musical passage, when it travels *round* a large organ, or seems to be travelling *away* from you and not to you. Of course not everyone can do this in performance, but Mr. Turle had the knack of it; and one hardly knows how musical skill and resource could be better exemplified, or a more wonderful effect produced; indeed, when well done, it doubles the power of a musical passage as it comes from the composer's hands. Thus it will be seen, partially at least, for space does not allow me to say half that is needful, what an amount of loss, musical and architectural, and mischief has been accomplished by the tampering with and the pulling to pieces of this organ. Now that the fashion is once started and on the move, it is very greatly to be feared that every cathedral organ in the country is in like manner doomed to destruction. The Temple organ, a much finer one than that at the Abbey, is shut up in a "stone box;" the St. Paul's organ is only to be found after a tiresome search after it; Canterbury finds its organ in the roof; and Westminster is distributed about in bits, and just where it cannot be played. Ought not education to commence with the upper classes? and can it be wondered at that the poor dull clerks in offices do such wretched work when those whose opportunities are so much higher are found to not only sanction but advise such destructive and ignorant policy. Westminster Abbey has yet to be *restored* in the future: let us hope that the great work will commence now with its organ.

C. B. A.

SCIENTIFIC POPULAR LECTURES FOR THE PEOPLE.—EXAMINATION AND PRIZE SCHEME.

IN anticipation of the third season for the delivery of a course of familiar scientific lectures prepared by Thomas Twining, Esq., in connection with his Economic Museum at Twickenham, that gentleman has propounded a plan for examination, and offered prizes to be competed for by the attendants at his lectures. The course will embrace the subjects of physics, chemical physics, chemistry, natural history, human anatomy, and human physiology. Arrangements are at present made for the delivery of the course at the Lambeth Baths, and, although Mr. Twining will be happy to receive proposals for the gratuitous delivery of the lectures in other localities, the examination and prize scheme is for the present limited to the Lambeth Baths, where the most numerous and attentive audiences have been present in past seasons. One of the examiners will be Mr. William Hudson, chemical superintendent of the Twickenham Museum; another will be the Rev. G. M. Murphy, and a third is to be named by the Society of Arts. Mr. Twining has desired special precautions to be taken to exclude all except *bonâ fide* working class competitors. It is sincerely to be hoped that this practical attempt at popular, technical, and scientific instruction will meet with the success so well meant an endeavour deserves. It is to be followed, according to present arrangements, by a South London Industrial Exhibition in the Lambeth Baths, opening early in March next.

ARCHITECTS AND CLERKS OF WORKS.

AT the last meeting of the Islington Board of Guardians a letter was received from Mr. Burden, the architect of the new workhouse, directing the attention of the board to the report sent weekly by Mr. Lewis, the clerk of the works, and stating that Mr. Lewis was taking a position very unusual for a clerk of works. A clerk of the works was at the disposal and service of the architect, and he held his office subject to the approval of the architect. Such was the tenor of Mr. Burden's note. A long discussion ensued, in which it was conjectured that Mr. Burden referred to the instructions given by the board to the clerk of the works to make a weekly report and to condemn all bad materials. One of the guardians said that the clerk of works had no power to condemn materials himself. His duty was to report the circumstance to the architect. Another guardian contended that the clerk of works was appointed by them to look after their interests, and was paid a high salary in order to render himself independent of both architect and builder. A third guardian thought that the clerk of works had no power even to stop work, whereupon he met with the rejoinder from another guardian that if that was so the clerk would be perfectly useless, for only the other day he stopped the putting in of some defective joists, and had he not possessed this power the joists would have been covered up and no one would have known anything about them. Mr. Fairbank, a guardian, said that he should have been better pleased with Mr. Burden if he had ordered the pulling down of that portion of the building containing improper material, so as to punish the builders. Mr. Miles, another guardian, said that they had the distinct assertion of Mr. Burden that no improper materials had been used in the building. Mr. Box, another guardian, said that it should be recollected that

the clerk of the works called the attention of the architect to the defective materials, and that it was only when the architect failed to order their removal that the clerk of the works reported the circumstance to the board. It appeared to him (Mr. Box) that Mr. Lewis, the clerk of the works, had thoroughly performed his duty. Some further conversation ensued, and it was resolved to order Mr. Burden to attend the next meeting of the board to state his grounds of complaint against the clerk of the works.

THE ROTHERHITHE DISTRICT ASYLUM.

A PARAGRAPH appeared in a recent impression stating that the Metropolitan District Asylum Board were about to erect a new sick asylum at Rotherhithe to accommodate 500 patients, at a cost of £30,000. It seems that the Board are now somewhat divided in opinion as to whether they should avail themselves of architectural or medical assistance in deciding upon the plans for the new building. The *South London Chronicle*, in some judicious remarks on the subject, suggests that, as both professions are concerned in the matter, both should be invited to aid in settling it. The medical man can best tell to what extent the health of the patient is likely to be affected by structural arrangements, and the architect can tell whether the requirements of the medical profession can be met with a due regard to difficulties of construction and the money to be expended. If full swing is given to the absolute requirements of either medical men or architects the result will not be so satisfactory as a whole, while a fusion of interests will be not only compatible with good arrangements, but absolutely essential. The plans for the new structure are all upon the pavilion principle, the only method upon which a proper isolation of the sick, with that amount of quietness, rest, and freedom from noxious exhalations which is necessary for their speedy recovery, can be attained. The days for the erection of a large hospital, says the *Chronicle*, with tier upon tier, telling of the magnificence of the architect and his ignorance of the fact that exhalations from the lower sick wards ascend to those of the upper stories, increasing the danger of contagion with the height, are gone by. Our hospitals of the future will spread themselves over a wider extent of ground, they will take advantage of the pure air of the country, be divided into several blocks of buildings, and be fitted with every appliance that the most advanced medical skill can suggest. Architectural beauty, while it must not be neglected, for it has a soothing and even restorative power of its own, must be sought in the inexpensive method of beautiful forms (and this is beauty of the highest kind), not in florid and expensive ornamentation.

OBITUARY.

ON the 23rd of July last, Mr. G. R. Burnell died at his residence in Kensington Gardens-terrace, in the 54th year of age. He was a well-known writer of several scientific works. His attainments were numerous. He had extensive knowledge of languages, and had resided in America, France, and Belgium, besides visiting Spain and Sardinia. About seven years of his life were spent in France, during which time he was engaged on the Paris and Rouen Railway, and as superintending architect of the Havre Docks. On the cry being raised of "*La France pour les Français*," in 1848, he returned to England. Though he executed several works both here and abroad, his bent was decidedly literary. He contributed several articles to the BUILDING NEWS early in his career, especially on roofs. In 1857 he wrote a rudimentary work on "Limes and Cements;" in 1861, "The Annual Retrospect of Engineering and Architecture." He edited "The Builders' and Contractors' Price-book," and "The Engineers' and Architects' Pocket-book." He was connected, too, with the *Journal of Gaslighting* for many years, and wrote several papers for the Society of Arts, and for the Institution of Civil Engineers, for which he received prizes. He was the author of many articles in Brande's "Dictionary of Science," and in the "Dictionary of Architecture," published by the Architectural Society, especially one on the word "Abattoir." Mr Burnell was a relative of Mr. W. Tite, M.P., and at his suggestion was made a member of the Government Committee appointed to inquire as to the preservation of the stone of the Houses of Parliament—a committee, by the way, that sat long, published a useful report, and never received the slightest acknowledgment of its services. He was elected a member of the Society of Arts in 1860.

The death is announced of Mr. Samuel Mitchell, of Sheffield, well known for many years as a zealous antiquary. In 1831, Mr. Mitchell, in turning over the records in the Bodleian Library at Oxford, found, in the 40th volume of Dodsworth's collection, evidence of the fact that Sheffield had been destroyed by fire during the civil wars in the time of Henry III., an event which had subsided into oblivion. About this time, in conjunction with his friend, the late Thomas Bateman, of Youlgrave, Mr. Mitchell was engaged in exploring the barrows of North Derbyshire. The result of these explorations was described at the time in a volume by Mr. Bateman, and the well known Museum at Lombardale was enriched by numerous trophies, testifying to the perseverance of the explorers. Mr. Mitchell was a valued contributor to various antiquarian publications. On the formation of the Sheffield Architectural and Archæological Society at the beginning of this year, Mr. Mitchell, though in failing health, came forth to render his assistance, and was appointed one of the vice-presidents. Mr. Mitchell died in his sixty-sixth year.

ARCHÆOLOGY.

AN international archæological congress has just been opened at Bonn, Prussia. The proceedings were commenced by a speech from the venerable M. Noiggerotte, after which the Burgomaster of the town warmly welcomed the visitors. In the evening a banquet was given to 260 members assembled.

During the construction of the works of the Western Extension Railway under one of the fashionable squares in Paddington, the workmen discovered a quantity of huge antlers embedded in the soil at a considerable depth. In a stratum above were found Roman coins and other relics of a later age.

WATER SUPPLY AND SANITARY MATTERS.

THE Mayor of Southampton recently stated that the ratepayers of that town had to pay from £700 to £1,000 annually for water wasted by the inhabitants.

The vestry of St. Pancras have resolved to reconstruct the sewers in various parts of the parish at an estimated cost of £3,637, and Mr. Scott, the chief surveyor, in accordance with instructions given to him, has made a further report upon sewers in the parish that require reconstruction or extensive repair, in addition to those already ordered to be rebuilt, the estimated cost of which is £17,071, making together £20,907. It is proposed to borrow the money for these works, and to repay it by instalments spread over thirty years.

The Brixham local authorities have met with an unexpected check in regard to their projected water supply. The act obtained by the commissioners only gives them power to purchase in their own district, whereas the waterway and source of supply are outside their limits.

The association which has been formed to promote the constant system of water supply deserves all possible support. The present enforced practice of storing water in receptacles more or less open to pollution is (says the *Lancet*) most objectionable in a sanitary point of view, as in a large proportion of cases the trouble and expense incurred by the companies to supply a good quality of water are thereby entirely neutralised. It is true that under the old law as it at present stands the companies are required to give a constant supply upon the demand of two-thirds of their ratepayers; but, from the difficulty of securing the united action of a large body of persons this provision is to a great extent inoperative. The experience of Manchester, Glasgow, Edinburgh, Birmingham, and many other communities sufficiently attests that the objection entertained by the London companies to the constant system on the score of waste is untenable; the waste from imperfect fittings on the intermittent system is well known to be enormous. Both on the score of health and economy it is to be desired that the efforts which are being made to supersede the intermittent by the constant system may be successful.

In accordance with a resolution passed some time since by the Sanitary Committee of the Doncaster Town Council, Mr. B. S. Brundell, C.E., has prepared a report with reference to the drainage of the town. Mr. Brundell proposes a complete system of sewers, pumping works, &c., and that the sewage should be used in the irrigation of a large estate the property of the corporation. The total cost of the proposed works is £9,000, or £10,000, and there is every probability that this scheme will be carried out.

In the course of a few days the block of houses extending along the Poultry from the western side of the Mansion House will be removed for the purposes of the new street which is to run from that point to Blackfriars Bridge. On the north side of Cannon-street the ground has already been cleared, and in Earl-street, Blackfriars, a large number of houses have been removed, leaving an almost uninterrupted space between the bridge and the large building in course of erection for the British and Foreign Bible Society.

Building Intelligence.

CHURCHES AND CHAPELS.

The church of St. Ethelburga, Bishopsgate, has been reopened, after a short restoration. A large body of maroon colour round the entire body of the church, for about 6ft. from the ground, has the effect of apparently heightening the building. The ornamented roof above the sanctuary has been restored and the capitals of the piers gilded.

Yesterday week the church at Ruyton-of-the-Eleven-Towns, Salop, was reopened, after restoration. The church, which is dedicated to St. John the Baptist, is of Norman foundation, the chancel of that date remaining almost entire. It has been re-roofed and re-seated throughout, and generally restored. Mr. Pountney Smith, of Shrewsbury, was the architect.

The ancient church of Llantysillio is about to be thoroughly restored and re-seated at a considerable cost, under the care of Mr. Pountney Smith, of Shrewsbury. A fine old roof of oak (perfectly sound) has been laid bare, showing very rich work in the eastern bay; and the chancel screen, so general a feature in the Welsh churches, is here found in fragments used up in benches, galleries, and other fittings. There is a curious and very ancient eagle lectern, belonging originally, it is said, to Vale Cruscis Abbey, preserved in this church.

On Tuesday week the foundation stone of a new Roman Catholic Church was laid at Old-coates, Lincolnshire. The architects are Messrs. Wilson and Nicol, and Mr. Athron, of Doncaster, is the builder.

The parish church of Cardington was reopened on the 11th inst., after restoration. The old roofs have been removed, the galleries taken away, and the church re-seated. The chancel and sanctuary are paved with Maw's tiles, and warming apparatus provided. The cost of the work was about £1,200. Mr. H. Curzon, of London, was the architect, and Messrs. Nevett Bros., of Ironbridge, the contractors.

The Cathedral of St. Lazare, at Auteen, has been inaugurated, after a thirty years' restoration, under the direction of M. Viollet le Duc and M. Durand.

On the 16th inst. the new church of St. Matthew, Leyburn, Yorks, was consecrated by the Bishop of Ripon. The style is Decorated Gothic, of the period of Edward III, the plan consisting of a nave 57ft. long by 23ft. wide, with a north aisle 13ft. wide, and chancel 24ft. by 18ft. The walls are faced with hammer-dressed freestone in parallel courses. The quoins and dressings are of ashlar. The cost of the building is slightly under £3,000. Mr. C. G. Wray, of London, is the architect, and Mr. Jones, of Leyburn, the contractor.

A new Independent Chapel was opened on the 17th inst. at Broughton, near Kettering. The style is Gothic, the chapel being built of the common stone of the neighbourhood, the front being banded by black brick and local freestone. Accommodation will be provided for 250 persons. Messrs. Habershon, Brock, and Webb are the architects, and Mr. Charles Dawkins, of Broughton, the contractor.

Whitfield's Tabernacle, Moorfields, is now being rebuilt. The laying of the foundation stone was mentioned in a recent impression. The style of the edifice is Gothic, and accommodation will be afforded for 1,000 persons. The architects are Messrs. J. R. Searle and Son, Bloomsbury; and Messrs. Dove Brothers, of Islington, are the builders. The cost will be £7,000.

A new Congregational Chapel was opened at Hythe on the 16th inst. The style is Gothic, and the building is constructed of local rock stone. The cost is over £2,500. Mr. J. Gardner, of Folkestone, is the architect, and Messrs. Candy and Gibbs, of Croydon, have executed the carved work under his direction.

On Monday the foundation stone of a new church, dedicated to St. Bridget, was laid at Wavertree, near Liverpool. The style is based upon the best known examples of the Roman Basilicas. The dimensions are—length, 126ft.; breadth, 60ft.; the east end terminating with a semi-circular apse. The columns supporting the roof of the nave will be of Irish marble. The cost will be about £6,600. Mr. E. A. Hefler, of Liverpool, is the architect, and Messrs. Nicholson and Ayre, of Toxteth Park, the contractors.

On Tuesday last the new church of the Holy Trinity, Cornforth, Durham, was consecrated by Dr. Anderson. The style is Early Decorated, a French character being observable in many of the features. The plan consists of nave, chancel, and aisle, with organ chamber and vestry. The church is built of red pressed brick, intersected by bands of a darker colour, with dressings externally of Casterton, and internally of Caen stone. It will seat 300 persons, at a cost of £2,000. Mr. J. P. Pritchett, of Darlington, is the architect, and Messrs. Dodson and Foster, of Stockton, the contractors.

Alterations and improvements have recently been made to the parish church of Rhôsmarket, Pembrokeshire, from designs prepared by Mr. E. H. Lingen Barker, architect, of London and Hereford. The principal additions have been a vestry and western bell tower, the former having been much needed. The work was entrusted to local tradesmen and has been satisfactorily carried out.

On Tuesday the Bishop of Gibraltar consecrated a new church at Hednesford. The church is Early English in design, and seats 500 adults, at a cost of £3,000. Mr. W. Rushforth, of Regent-street, London, is the architect, and Mr. Anderson, of Cannock, the contractor.

On the 15th inst. the new church of St. John, Llanbrynmair, Montgomeryshire, was consecrated. The style is twelfth century Gothic, with much of the character of Early French work. The walling is of local stone of a deep blue colour, with bands of a lighter blue colour introduced for contrast. The plan consists of a nave and chancel under one roof, the chancel terminating in an apse. Mr. D. Walker, of Liverpool, was the architect, and Mr. J. Harrison, of Newtown, the builder.

The foundation stone of the new Congregational Church, Mere, Wilts, about to be erected by Mr. C. Jupe as a memorial church, was laid on Wednesday last. The building will be in the Late Early English style, and will have nave, north and south transepts, aisles, and polygonal apse at the east end, in which will be placed the pulpit and communion table. Galleries will be carried all round, except in the north transept, which is reserved for the organ and choir. The clerestory will be carried on 6in. iron columns. There will be three entrances, one in south porch, one on north side of west front, and the principal one through a lofty porch at south-west angle of church, which has been so designed that it may be left as a porch, or form a suitable base for a tower and spire, should it ever be decided to build them. There will be accommodation for 350 persons on the ground floor and 220 in the galleries. Mr. W. J. Stent, of Warminster, is the architect.

Perwall parish church, Middlesex, was reopened on Sunday last after undergoing enlargement and restoration, which comprised building a new organ chamber, entire relaying of the floors of nave and chancel, new open seats for the nave, and stalls for the choir in the chancel; a new prayer desk has also been added. The whole of the woodwork is stained and varnished. A new window has been inserted in the south side of the nave. Several of the windows have been filled in with stained glass as memorials. New altar railings have been substituted for the old ones. The church is of the Transitional period of Early English architecture. The whole of the works have been carried out by Mr. Nye, builder, of Ealing, under the superintendence of Mr. Charles Jones, architect, of Ealing.

BUILDINGS.

The committee for building a new mechanics' hall at Otley, Yorkshire, have selected a design. Nineteen designs were submitted in competition by architects from Leeds, Bradford, and other places, all sent in under motto. The design and plans selected are by Mr. Chas. Fowler, architect, Leeds. The style is Italian, and the following are the chief features of the internal arrangements:—On the ground floor there will be a lecture room holding 250 persons, and which, if desirable, may be divided into two class rooms; there will also be retiring rooms, reading room, library, two class rooms, lavatory, &c. The basement will contain kitchens, scullery, chemical class room, heating apparatus, &c. On the first floor will be the large hall, with gallery, platform, and orchestra, and space for organ. A librarian's residence will be attached. The large hall, including gallery and orchestra, will seat 1,000 persons. There will be two staircases and three separate entrances and exits into and from the large hall. The building will be built of stone, at an estimated cost of £3,000.

Extensive alterations and additions have recently been made at St. George's Hospital. A piece of land to the south of the old building having been presented by the Marquis of Westminster a new wing has been erected on it, and a new and commodious out-patient department has been arranged on the north side, having an entrance and exit distinct from the general entrance to the hospital. A great portion of the new buildings have been devoted to the purposes of the school of medicine. The lecture theatre is a capacious amphitheatre, fitted with stained woodwork, and capable of holding 200 persons. A smaller theatre, with laboratory, is devoted to the chemical lecturer. The walls of the dissecting room are tinted and adorned with anatomical plates.

The foundation stone of a new general hospital and dispensary for sick children was laid at Manchester on Friday last. The building will cover a plot of ground of 530 square yards. The front will be executed in stock bricks, with stone dressings, mediæval in character, and will consist of a central gable, with open porch, the tympanum containing a medallion of figures illustrative of the purpose of the building; on each side a range of five arched windows will be surmounted by a frieze, with an inscription in coloured tiles. A moulded stone cornice and high pitched roof will complete this elevation. Messrs. Mills and Murgatroyd, of Manchester, are the architects, and Messrs. Neill and Sons, the builders.

A block of buildings, comprising four villas, has recently been completed at Chogford, Devon. They have been converted from ten small cottages which formerly stood upon the site, and such of the old walling and materials as were found sound and suitable have been re-used in the new buildings. They have been erected to supply the increasing demand for lodgings in this romantic and much frequented locality during the summer months. Mr. Williams, of Bristol, was clerk of the works, which were carried out by local tradesmen. Mr. Robert Clamp, of Totnes, was the architect engaged.

TO CORRESPONDENTS.

NOTICE.—Cases for binding the BUILDING NEWS, Vol. XIV., are now ready, price 2s. each.

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

RECEIVED—H. H. S.—C. L.—B. and P.—I. P. S.—G. T. R.—W. C. T.—S. W. and Co.—I. P. S.—I. R.—T. S. L.—E. W. G.—A. P. W.—C. B. A.—W. B.—H. H. S.—H. I. D.—E. W.—C. and G.—I. N. C.—G. W. B.—F. W. R.—I. S. S.—W. W.—W. C.

BUILDING SOCIETIES.

To the Editor of the BUILDING NEWS.

SIR,—We appear now to have arrived, by common consent, at two conclusions—viz, that building societies *do* charge 7½ or 8 per cent. for their loans (they really charge more, for they declare dividends at those rates, but let that go); and, second, that in order to borrow profitably at that interest you must be able to obtain house property at eight years' purchase. These two admissions entirely establish my position. "The operations of the benefit building societies," as stated by themselves, "are based on the fact that tenants pay to landlords a much larger sum under the name of rent than the ordinary interest upon the sum which would buy the house. A tenant, therefore, who borrows from a building society to buy a house will save the difference between the interest of the money invested in the house and the rent usually paid for its occupation. This saving, if allowed to accumulate at compound interest, will eventually replace the purchase money." We have seen that borrowers pay to the society 7½ or 8 per cent. in *addition* to the ground rent and annual charges and risks. Now do tenants pay *more* than 7½ or 8 per cent. to their landlords, in addition to the annual charges on the property? That is, do landlords reap a *nett* profit in excess of the interest charged by building societies? If not, where is the difference which is to accumulate and replace the principal?

Hear Mr. Bailey Denton, in a communication of this date, to the *Daily News*:—"With the middle and commercial classes living in towns, it is different, though they occasionally spend large sums of money to gratify their taste for building, which cannot command a fair return. In the long run, however, the building of houses in towns, if conducted with ordinary prudence, is remunerative; but it is only considered *satisfactory* when it yields at least 7 per cent. return on the outlay, whereby the principal money may be repaid during the period of duration with 5 *per cent. interest on the outlay, after payment* of repairs and insurance."

It is clear that his experience agrees with mine, and not with that of some of your correspondents. I do not deny that there are houses which are to be bought at the rates quoted by your correspondents, but I know, as a surveyor, that such cheap houses are the dearest of houses, and are no reliable bases for general inferences. The annual provision for repairs would have to be larger than we have assumed it, and in all probability the house would then "fall in" before the lease.

The outcome of it all seems to be that, if you are paying your landlord *more* than 7½ or 8 per cent. on the *nett* value of the property, you can use the advances of building societies with advantage; whereas, if you are, on the other hand, paying the normal rate—say, 6 or 6½ on the nett value—by way of rent, it is the merest folly to have any dealings with them except as an *investor*.

—I am, &c., E. INGRESS BELL.

September 22.

P.S.—My acknowledgements are due to those gentlemen who pointed out an inadvertence in my statement of case No. 2 last week.

SIR,—In the interesting discussion on this subject which has recently appeared in your journal some highly important facts of great advantage to the purchasers of property through building societies have been strangely overlooked by your correspondents. As these facts most seriously affect the calculations which have been published in your columns, I beg to mention them. I allude to the very great difference between the low charges and the survey fees of building societies and those made by solicitors and surveyors to the general public, and to the circumstance that the legal documents of building societies are exempted from stamp duty. The society to which I belong would, for the case of a loan of £300, supposed by Mr. Bell, charge—law expenses, four guineas; survey fee, one guinea. The usual charges of solicitors and surveyors in such a case are, perhaps, five times as much, independent of stamp duty.—I am, &c.,

A DIRECTOR.

Carlton Hill, September 21.

MODERN CHURCH BUILDING.

SIR,—I have read with great satisfaction the series of papers which have appeared in your journal on the subject of chapel architecture. The matter has been treated in a thorough and masterly manner, and I hope we may see some result from the valuable hints which have been thrown out. But chapel architects are not alone in fault. I wish something could be done to infuse into the minds of church designers more common sense and independent action, especially as regards the sanitary requirements of their buildings—heating and ventilation. During the present summer the flagrant deficiency of ventilation in churches has been severely felt. And no wonder; ventilation architects rarely trouble themselves to think about. A few hopper casements are, perhaps, provided in the windows, but, should there be stained glass, the casements are omitted and nothing done. As to any special arrangement in the roofs or gables, in the absence of ancient authority for such a thing, it is either not considered worthy of consideration or too troublesome a matter to meddle with. And with respect to the warming, how rarely does this receive thought and proper attention! By many the heating is regarded as an extra, and when, as is often the case, a difficulty is found in the cost of the church, the heating chamber, &c., is omitted, and a miserable makeshift of unsightly stoves, or some other imperfect process, is the result at a future time. In

winter the coughing in church is often not only painful to the hearers but at times interferes with what is going on. Many, I doubt not, catch their "death of cold" in attending public worship. And what wonder when not only is the place insufficiently warmed, but people are sitting in wet clothes and with dripping umbrellas for two, or, it may be, three hours at a time! To all churches there should be a cloak room with an attendant, and in inclement weather a good fire, so that people may dry themselves and leave wet clothes, &c. All entrances should have porches or lobbies, and these warmed.

Why should those precautions which are necessary for health be disregarded in churches more than in other buildings? Our present churches with their savage incompatibility with modern civilization are positively dangerous to health. I, for one, though partial to the church service, dare not attend in winter.—I am, &c., P. E. M.

STREET LIGHTING.

SIR,—Already complained of as failing in my duty as a light to lighten the gentiles, I am made a stumbling block to them in addition by being placed within a few inches of the centre of the narrow footpath in the *too* narrow thoroughfare called "the Poultry"—the main road through the chief city in the world. Oh dear! what will become of me, what with the omnibuses and other vehicles threatening every moment to damage my personal appearance in the upper regions, and the bustling, rushing, pushing mass bruising my poor stump! Sir, I must be moved from here or else I shall one day come to grief, and I appeal to you for help. Of the two evils, Sir, I prefer having my head bumped occasionally by vehicles to having my trunk subjected to the knocks, swearings, and execrations of the time-racing city mob; but if the officials are willing to satisfy both the public and myself, I would suggest that (much as I object to capital punishment) I should be "hung" and put out of the way at once. My mediæval ancestors were hung across the street, my parents have been and are still in many places suspended on brackets, and I am not ashamed to say that I prefer to "shine" in either of these methods, rather than be called a nuisance, and said to be always in the way. Sir, pity the sorrows of a poor

LAMP-POST.

THE ORGAN IN WESTMINSTER ABBEY.

SIR,—Let me make a suggestion which may satisfy your correspondents "C. B. A." and "W. C. J." If the authorities of the Abbey will take down the organ from its present situation, screen and all, and re-erect it, greatly strengthened and enlarged, on the screen, which is sufficiently handsome, over the west door of the Abbey (the screen being turned round to face east), a new and magnificent view of the interior would be obtained, never before visible: the organ, too, would sound there better than it has ever yet done, having the advantage of the west wall of the church behind it, to throw the sound forward as from as a sounding board. Those who know the glorious effect of the voluntaries played on the great organs over the western doors of Notre Dame, St. Eustache, and St. Sulpice, in Paris, to mention only a few, will know what I mean.

Should this ever be done, an organ of moderate size would be indispensable for accompanying the singers in the choir, the position of which could easily be arranged under one of the side arches of the choir, over the stalls, all voluntaries, &c., being played on the western, or grand organ. With the new electrical apparatus lately introduced it would be perfectly possible for *one* organist to play *both* instruments from *one* place, and we should thus have a realisation of that admirable effect so universal in the great churches in France, and so unknown in England, of the grand organ at the west end of the church, and the smaller organ in the choir, being played alternately at the *same* service. This is already attainable in St. Paul's Cathedral, with its grand organ in the south transept and its lesser organ in the choir, but I have never heard of the alternate use in *one* service being attempted as yet, though I hope it will be done some day.

I should add with regard to Westminster Abbey, that the west window is sufficiently high from the ground to admit of a very large organ, on a gallery, being placed under it, without any concealment of the stained glass. I enclose my card. —I am, &c., WESTERN ORGAN.

London, September 21.

ST. PAUL'S ORGAN.

SIR,—I am uncertain as to the precise meaning of the last paragraph in the letter of "W. C. J.," but I take leave to infer that he considers the removal of the organ to the side of the choir to be a mistake. I am sure that yesterday my ears gave me proof that its former position was the best, the neighbourhood of the dome allowing of the expansion of the sound formerly, whereas now it crushes down on the congregation and overpowers the voices quite as much as in many parish churches where the organist seems to think himself bound to conceal the poverty of singers. I say nothing, *pro* or *con*, with regard to the position of the organ in an architectural point of view, except just to remark that *mere length* in a building is not a beauty; and, therefore, I think the notion of removing organs (which I believe was first tried at Winchester) simply for the purpose of extending a view is a mistake. But I am sure that to thrust a powerful instrument close among a number of vocalists is both physically and musically wrong. Both architects and organists are apt to think that their work is the most important; and yet when a methodist preacher vociferates they condemn him for bad taste. Now, the mistake is in all three cases bad proportion. The architect thinks sometimes that the longer he can make an aisle the finer the effect. The organist thinks the more sound he can get to swell a chorus the more impressive the music, but both are just as mistaken as the ranter who thinks that by loud speaking he produces more impression on his audience. Speaking particularly of the organist, there is no more decided proof of his unfitness to lead public worship than his ignoring the number of the congregation—thinking only of his book, and playing by that at all times. This marks the distinction between the mere musician and the artist. Perhaps the former might grow into the latter if he considered more the *real* object of his work.—I am, &c., VIATOR.

September 23.

INDICATORS FOR PILLAR LETTER-BOXES.

SIR,—Those who are in the habit of posting letters in pillar-boxes would in most cases be benefited by knowing whether the particular post by which they may wish to send their letters has gone or not. This object, in some cases so important, may be easily attained by a very simple plan, which is in general use on the continent. On every letter box in France there is this notification affixed to its front, "La première (ou deuxième, &c.) levée est faite;" and I think, with a very trifling addition to the present duties of postmen, that after a box is cleared an indicator, visible from the outside, might be arranged with an inscription somewhat similar to the above, as for instance, "The 8.15 a.m. (or 9.45 a.m., &c.) collection is completed." If the adoption of this is objected to as causing a detention to the postmen, I would say in reply that it is possible so to arrange the indicator that it should be self-acting—the door itself working it by a simple arrangement. The above plan is more needed at pillar-boxes than at receiving houses, since at the latter the boxes are cleared more punctually; but at the former it frequently happens that a collection is not made until fifteen or twenty minutes after the appointed time. The advantages of course are obvious; for instance, it can be seen at a glance whether the box is cleared; and, again, if a person is desirous of hastening the delivery of a letter, and finds that the pillar-box is cleared, he can proceed to the nearest receiving house, and thus, in many instances, be in time for the same post. Of course, the general adoption of the plan for all letter-boxes would be still more advantageous.—I am, &c. R. L. B.

September 21.

CANAL BRIDGE, GLOUCESTER GATE.

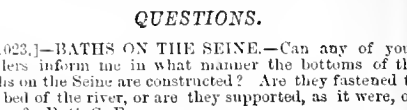
SIR,—May I, through your columns, call the attention of the authorities to the increasing necessity of widening the canal bridge at Gloucester Gate, Regent's Park? At present the footway is by far too narrow for even everyday traffic, but on Sundays it is positively dangerous to cross this bridge, the passing vehicles grazing the pushed and pushing foot-passenger in the most alarming manner.—I am, &c., A. C. G.

Intercommunication.

QUESTIONS.

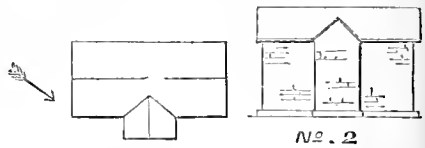
[1023.]—BATHS ON THE SEINE.—Can any of your readers inform me in what manner the bottoms of the baths on the Seine are constructed? Are they fastened to the bed of the river, or are they supported, as it were, on barges?—E. C. C. E.

[1024.]—TO EQUALISE AN IRREGULAR LINE.—I should be glad if some of your correspondents would be good enough to solve the following question?—To equalise a crooked line, thus—A B—by a straight line, as dotted,



without first having to draw an imaginary line, then to calculate the contents on each side of the imaginary line, and adjust the straight line according to the contents and the length of the line.—A SURVEYOR.

[1025.]—PROJECTION OF SHADOW.—I have often been puzzled when colouring a geometrical elevation to find the true projection of a shadow cast from a projection on to the roof. I should be obliged if some colourist



Nº. 1 Nº. 2

would be good enough to reply to this question. No. 1 plan of roof, No. 2 elevation, the sun to be the angle of 35° 16', and the light coming in the direction as indicated by the arrow.—DRAUGHTSMAN.

[1026.]—IRON AND WOOD ROOFS.—I want to cover over a building with roof of 40ft. span. Can I do this best and cheapest with timber or wrought iron? Perhaps some of your kind correspondents will oblige me with the particulars as to how far apart the principals should be both of iron and wood, and what will be the difference of cost between them? The covering, whether the principals are iron or wood, will be about the same; but I may as well state the building is to be used as a pattern-maker's and engine-fitter's shop, so that your correspondents can judge of the amount of light required.—IRON V. WOOD.

[1027.]—STEEL MAKING.—There being no steel mines or ores, what process does wrought iron bar undergo to become a steel bar?—TUBAL CAIN.

[1028.]—THE STRONGEST BRICKS.—Which is considered the strongest brick when laid in mortar, the perforated or the solid Bridgewater bricks?—BRICK CLAY.

[1029.]—INCLINE SWARDS.—What would be a safe incline or slope to ensure a constant greensward, equal to a horizontal level, that any subscriber would recommend; or, in other words, what angle should the slope be formed at?—PETER GROOME.

[1030.]—WORK ON PAINTING, GRAINING, &c.—I shall be much obliged if any of your correspondents can inform me what is the best practical work on painting, graining, staining, and varnishing, as I do not know of any which treats of it in a thoroughly practical manner.—THOMAS P. BOWEN, 27, Chatham street, Leicester.

[1031.]—THE MAGIC NUMBERS.—Can any of your correspondents inform me what are magic numbers, their properties, and why they are so called?—A. BEAVER.

[1032.]—HANDRAILING, STAIRCASING, &c.—I should feel obliged if you, or any of your correspondents, could inform me, through "Intercommunication," which is the best and simplest work for an amateur on staircasing and handrailing, where the same can be obtained, with the price, &c.? The booksellers here do not keep any building or architectural works in stock, and the mechanic's institute is very poorly supplied; having been a member for years, and have never been able to find but two works on architecture.—A JOINER, Coventry.

[1033.]—THE ARCHITECTURAL EXHIBITION.—Would you be kind enough to inform me when the next Architectural Exhibition takes place in London, and to whom I should apply for space to exhibit?—X. Y. Z., Birmingham.

[The next exhibition opens on May 1 next. Write to the secretary of the Architectural Exhibition, 9, Conduit-street, London, W.; or to J. R. Botham, local secretary, 47, Paradise street, Birmingham.]

[1034.]—MEASURING ARTIFICERS' WORK.—What is the best practical work upon measuring artificer's work and taking quantities, describing hollows, allowance for labour, &c.—A. BEAVER.

[1035.]—BOIS DURCI.—Can you tell me when this substance was introduced into England, and by whom, and also the proportions of the ingredients of which it is composed? I know the component parts are powdered sawdust and turnings of hard wood made into a paste with blood and pressed into moulds, but should be glad to learn the proportions, if not a trade secret?—JOINER, St Albans.

[1036.]—IMITATION TORTOISESHELL.—Can any subscriber tell me how to spot horn in imitation of tortoiseshell?—A. C., Lowestoft.

[1037.]—ETCHING ON IVORY.—I want a good recipe for a ground for etching on ivory; also the formula of some solution by which the design may be produced in red or black.—EUSTON-ROAD.

[1038.]—TOWNHALLS.—Can you tell me where I can obtain a book on Townhalls, giving me the necessary arrangements and number of courts, &c., required for a town of 15,000 or 20,000 inhabitants?—BEGINNER.

[1039.]—LANDLORD'S TAX AND SEWERS' RATE.—In my three years' agreement for the house I occupy I find among the conditions that the payments for rent shall be made "without any deduction or abatement whatever, and also shall pay and bear all rates, taxes, charges, and assessments payable in respect of the said house and premises (except the sewers' rate and landlord's property or income tax)." I have paid land tax and the main drainage rates. Both these my landlord refuses to allow me, under the plea that he is not liable by the agreement, and that land tax is not a landlord's tax, nor is the main drainage rate a sewers' rate. But, if not, what else is it? I shall be greatly obliged by an opinion on these matters.—R. G.

[1040.]—ST. MARTIN'S SCHOOL OF ART.—Can any of your correspondents inform me of the exact locality of the district school of art, St. Martin's in-the-Fields? I have inquired in the neighbourhood, but no one of whom I have asked seems to know of its existence.—ARTIST.

[The school is held at seven o'clock in the evening, in a large new brick building, Castle-street, Long Acre. The building is used as St. Martin's Northern School for Boys in the daytime.]

REPLIES.

[742.]—CRAYON DRAWINGS.—A recipe I have used for setting stump drawings, and which would, I therefore think, set crayon drawings also, was:—Rectified spirits of wine, 4oz.; oil of rosemary, 1dr.; white resin, 1dr. Pour over the drawing, and drain off surplus.—A. C. G.

[1017.]—CONTENTS OF CISTERN.—In reply to "Dilemma's" question, if he multiply the contents of the present butt in gallons by 3, it will be the number of gallons which the proposed cistern or tank must hold. Then divide that number by 6·25 (the number of gallons in a cubic foot); the quotient will be the number of cubic feet in the cistern. Extract the cube root of the quotient last found; it will give the length, breadth, and depth of the cistern to contain three times the quantity of the present butt, or the quotient divided by the product of any two dimensions, say length and breadth, the quotient will be the depth.—J. F.

[1017.]—Find the average diameter of the butt, and multiply this by 3 1-7th for the circumference; then multiply half the diameter by half the circumference, and this by the depth. The product will give the cubic feet, and these multiplied by 6¼, the amount of gallons contained in the butt. The cubic feet multiplied by 3 will give the size required for the cistern; and the size of the cistern must be so made as to cube to the same amount of feet. This will be the size required; and the cubic feet multiplied by 6¼ will give the amount of gallons contained in the cistern. This is not mathematically correct, but near enough for all practical purposes.—A. BEAVER.

[1017.]—"Dilemma's" question may be solved as follows: Ascertain the number of cubic feet of water contained in the butt in the following manner:—Take average diameter of water and the depth; square the diameter, and multiply by .7854, and then by the depth, which will be the number of cubic feet of water contained by the butt, which being multiplied by 3 equal the contents of tank required. If you require the tank any particular dimension one way, you must divide the sum by that, and find the square root for the other two dimensions; and if you have two dimensions and want the third, square the two dimensions and divide the sum by that, which will give the other dimension; but if not, find the cube root of the sum, and it will give you the side of a cube containing the amount of water. This is near enough for ordinary purposes; but if "Dilemma" wishes to be particularly accurate, if he will take very careful dimensions of the water-holding part of the butt I will work it out for him.—R.

*** Allow me to thank "A. P. B." for his ingenious short calculations.

[1018.]—STRENGTH OF ROPES.—In ascertaining the strength of hemp and iron wire ropes, the following formulæ appear to be what "S. P. C." requires. For tarred hemp ropes:—

c = circumference in inches.
x = breaking weight in tons.

$$x = c^2 \times 0.2.$$

For iron wire ropes—

$$x = c^2 \times 1.5.$$

In hauling, allowance must be made for tension, to obtain which the following formula may be used:—

R = weight of rope.
d = ratio of deflection from a straight line.
x = extra weight through tension in rope.

$$x = R\,d \times 0.13.$$

To obtain R in pounds per fathom:—

c = circumference of rope.
$R = c^2 \times .20$ for iron wire ropes.
$R = c^2 \times .87$ for hemp ropes.

Factor of safety 1 6th.—A. P. B.

[1018.]—"S. P. C." can find the breaking weight for ropes by the following rules:—viz., hemp rope, multiply the square of the circumference in inches by 0·2 and the product will be the breaking weight in tons. For wire ropes, multiply the square of the circumference in inches by 1·5, and the product will be the breaking weight in tons. The hemp rope is supposed to be tarred; if not tarred it will be about 5 per cent. stronger.—J. F.

[1018.]—In answer to "S. P. C.," I forward the following, from "Hurst," which will perhaps answer his purpose:—Circumference in inches being represented by c; the breaking weight in tons = $0.2\,c^2$ for hemp, and $1.5\,c^2$ for iron wire. When ropes are strained, as in the act of hauling, the tension arising from their own weight is greatly increased. Therefore, add to the weight to be moved that of the rope multiplied by the number opposite to the ratio of deflection from a straight line, as given in the following table:—

Ratio of Deflection	1-40	1-20	1-15	1-14	1-13	1-12	1-11	1-10
Multiplier	5·200	2·536	1·943	1·823	1·700	1·572	1·460	1·340

Factor of safety = 1 6.—R.

[1022.] AREA OF A FIELD.—If "Young Surveyor" would take my advice, he would measure the field again, getting the following lengths:—B D and the two perpendiculars upon it from C and E; also B F and the perpendiculars from A and E to B F. These are all that are practically necessary, the others being secondary dimensions. Now, proceeding as follows, he will obtain a sufficiently accurate result:—Multiply B D by half the sum of the two perpendiculars I before mentioned from C and E, and he gets the area of B E D C; then, multiplying B F by half the perpendicular on that line, he obtains the area of A F E B, which, added to the preceding, gives the total for the field; and an infinitely easier and shorter way this would be than working out the figures he gives (though I must not omit to mention it is impossible to obtain from them an accurate answer, and for this reason, viz., that it is possible for the point F to be in two different positions, and yet without interfering with any of the dimensions given, showing at once, if not previously seen, that the measurements are deficient—B F being wanting). Having now shown him the shortest of all plans to get at the area, I will proceed to explain how I would work to find the result from his figures. I would take it in four triangles; find the area of each, and the total of which would, of course, be the contents of the field. 1. The triangle E D C. Let S represent half the sum of its three sides, i.e., 1035; then take the lengths of the three sides severally from S, and I get 90, 95, and 850. Multiply 1035 by 90, the result by 95, and this result by 850. Finally, the square root of this last total gives the area of the triangle C E D, which, of course, is in feet, and has to be reduced to acres, &c. 2. Proceeding likewise, I obtain the area of B E C, and having got the length B F, which I believe to be about 216ft.; treat the two triangles, A F B and E F E, as before. Adding these four results together I get the area—a very laborious and undesirable task. I have now shown "Young Surveyor" how to get at the total contents as he asks, and by two different methods; but, if I am not sufficiently explicit, I am willing to answer any further questions on the subject.—J. MCNAMARA.

[1022.]—In answer to the question of your correspondent "Young Surveyor," I would ask him if he knows how to find the area of a triangle? and would then suggest that nothing could be easier than to divide his figure into three triangles. If he cannot quite comprehend this, he must not only be a very young surveyor but a very dull one.—W. E. B.

[1022.]—Assuming that the length of B F, which is omitted in this question, is 210ft., as given in question 1003, the area of the figure A B C D E F can be found in the following manner:—Find the area of each of the triangles A B F, B F E B C E, and C E D separately, and the addition of these areas will give the area of the whole figure. Now the area of a triangle is found by the following formula:—$\sqrt{s\,(s-a)\,(s-b)\,(s-c)}$, where s represents the semi-sum of the sides a b c, of the triangle. Applying this formula, we find that—

$$A\,B\,F = \sqrt{301 \times 105 \times 105 \times 91} = \sqrt{301985775} = 17377.73.$$

$$B\,F\,E = \sqrt{347.5 \times 137.5 \times 182.5 \times 27.5} = \sqrt{238902148.4375} = 15185.38.$$

$$B\,C\,E = \sqrt{1097.5 \times 777.5 \times 152.5 \times 167.5} = \sqrt{21796641523.4375} = 147636.85.$$

$$C\,E\,D = \sqrt{1035 \times 90 \times 95 \times 850} = \sqrt{7521862500} = 86728.07.$$

Thus the area of the figure A B C D E F = 267228.63 sq. feet, which = 6a. 0r. 21p. 16yds. 7.3ft.—R. L. B.

[1022.]—It appears that "Young Surveyor" has even with his corrected measurements given a problem for solution which cannot be solved unless the figure be plotted to scale. To compute the area of an irregular piece of ground from a rough diagram it is necessary that all the lengths necessary to throw it into triangles should be given. "Young Surveyor" has given one length (AD) which is not required, but has omitted to give the length AE, which is necessary to get the size of the triangles ABE and AEF. I have plotted the field and find AE = 340ft. Having found this quantity, "Young Surveyor" should proceed by the rule given by R, or by logarithms; the rule is add the logarithm of half the sum and those of the three remainders together; half the sum of these four logarithms will be the logarithm of the area. Of course if "Young Surveyor" has plotted the field he can find the area with much less trouble by dividing it into two irregular quadrilateral figures, and multiplying the mean length of each by its mean breadth.—ANOTHER YOUNG SURVEYOR.

WAGES MOVEMENT.

THE night-soil men of Newcastle-on-Tyne have struck work in consequence of a proposed increase in their hours of labour, and at the same time a slight reduction in their wages. The corporation scavengers have been applied to to assist in emptying the ashpits, but have refused.

The dispute which occasioned the labourers' strike at Leeds, which was referred to Mr. W. St. J. Wheelhouse, is now settled, it being decided that there was no proof of the men having received the notice for a reduction of wages, which was sent through the post. The men will therefore continue to receive 4½d. per hour as before.

STAINED GLASS.

TWO stained glass windows, by Messrs. Powell and Sons, Whitefriars, have been fixed in the openings on the south side of the church of St. Mary-le-Bow, Cheapside. The design is simple, consisting of panels divided by what are technically termed "German rounds." The details of the ornamental part are in strict accordance with the style of the building.

St. Mark's Church, Broadwater, Tunbridge Wells, has lately been enriched by the insertion of six new stained glass windows, from the works of Mr. O'Connor, of Brewer-street.

LEGAL INTELLIGENCE.

CONTRAVENING THE IMPROVEMENT ACT.—Mr. James Moseley, the chairman of an organisation known as the Leeds Property Owners' Protection Society, was charged before the Mayor of Leeds, last week, with a breach of the sixty-eighth section of the Leeds Improvement Act. Mr. Moseley is the agent of a house situated in Bakehouse yard, Pollard's-yard, Mill Garth street, a bedroom of which adjoins a privy, whilst the wall of an ashpit forms at the same time the wall of the living room of the house. Notice of the nuisance had been given to the defendant in November last, and as he had neglected to remove the cause of complaint, he had according to the statute rendered himself liable to a fine of £284 this sum being made up by accumulative penalties of twenty shillings a day. Dr. Robinson, the officer of health, asked that the penalty should be enforced, as there were many cases of the same kind, and as houses situated like that in question were dangerous to the public health. Mr. Moseley stated that as the notice had been given so long ago, and he had heard nothing of it since, he had imagined that no action would be taken against him, but the Mayor reminded him that this only showed how forbearing the authorities had been. He was fined in the mitigated penalty of £20.

Our Office Table.

The Chelsea Vestry have, it is stated, the credit of being the first to put in force the Artisans' and Labourers' Dwelling Act. At their last meeting, with reference to a nuisance in Wickham-place, Mr. Armstrong moved that the new act should be put in force, a proposition which was seconded and carried.

In the demolition of the old Middle Temple Hall and the simultaneous construction of the new building, rapid progress is being made, as also with the projected alterations in Crown-office-row, Lamb-buildings, and Tanfield-court, and a new Gothic entrance is just completed to the treasurer's office. The roof of the old hall (now being removed), said to be the best piece of Elizabethan architecture in London, was built in 1572, and it is related that the screen, in the Renaissance style, was made of the spoils of the Spanish Armada; but this is an error, as the records of the society prove that it was set up thirteen years before the armada put to sea.

It is said that a Co-operative Building Society is in contemplation at Birmingham.

Guildhall narrowly escaped destruction by fire on Tuesday afternoon. Some boiling turpentine used by some of the workmen ignited, and, as usual, when recourse was had to the hydrants in the adjoining yard, which ought to be available at any moment, it was found that only three had the hose attached; and no one knew where to find the key to turn on the supply. Fortunately, sufficient water was obtained from other sources to extinguish the flames.

At the last meeting of the Greenwich District Board of Works the pumping station at Abbey Mills was one of the subjects of discussion. One gentleman expressed his regret that so great a sum as £200,000 should have been expended on the building, which he considered as being too magnificent for its purpose, and as resembling a Chinese temple or Turkish mosque. No music hall in London, he said, could come up to it for embellishments; its towers, gables, tesselated pavements, &c., he considered out of place, and the lavish expenditure thus incurred was unjust to the ratepayers. A resolution was passed expressing dissatisfaction with the amount of money expended on the pumping station.

A large piece of ground near York-road station, Battersea, has been taken as the site of a proposed West London Meat and General Market. The situation is central and convenient.—The success of the King's Cross Market, opened some weeks ago, has been so marked that the inhabitants of Islington are talking about establishing a similar market on a large piece of ground in the rear of Church-street, and having entrances from Islington Green and the Essex-road.

At the last meeting of the St. Pancras Board of Guardians the clerk presented certificates from Mr. E. C. Robins, architect of the new relief offices, in favour of Messrs. Scrivener and White, builders, for "extras." A guardian said that he had understood that there were no "extras" connected with the building, whereupon Mr. Furniss said that "the architect was not yet born who could undertake a building without extras." The payment was allowed.

The executive committee of the Leeds Fine Art Exhibition have decided that it shall close on Monday, October 26.

The Limehouse District Board have petitioned the Court of Common Council, in the event of the proposed removal of the fish market from Billingsgate, to re-establish the market at Shadwell. Among the advantages which they claim for the district is that it is the nearest site to the City abutting on the Thames, and really suitable for the new market.

The general excursion of the members and friends of the Norfolk and Norwich Archæological Society, in conjunction with the Suffolk Institute of Archæology, took place on Thursday, the 16th inst. The members had been advised by circular to meet at Haddiscoe Station, at a quarter past ten o'clock, and here about fifty ladies and gentlemen were assembled; omnibuses and carriages were in attendance to convey them, and the party was further increased during the course of the day. Mr. Phipson explained that Mr. Fitch, of Norwich, was unable to attend, and that he would be happy to take his place. The various places visited were Haddiscoe Church, Haddiscoe Thorpe, Toft Monks, Fritton, Herringfleet, Blundeston, and Flixton Ruin.

Dr. Smith and Mr. Dancer have been examining the air of Manchester by the aid of the microscope, and have found it to be full of spores and other organic germs, the presence of which in, probably, all air leads, no doubt, to the phenomena imputed to spontaneous generation, and is probably the cause of the epidemic character of many diseases. The air was first washed by shaking it in a bottle with distilled water, and in a drop of the water it was reckoned that there were about 250,000 spores, and these only required to be lodged in suitable situations to spring into activity. In the quantity of air respired by a man in ten hours it was reckoned that there would be about 37,500,000 of these spores or organic germs.

The Palace at Cheragan, on the Bosphorus, is so far advanced that the question of furnishing is under discussion, and as a matter of course the French are trying for the job. We may say, too, as a matter of course, one does not here of Englishmen looking out, notwithstanding the high character of English work in Turkey. A strong party is in favour of Turkish material and Turkish workmen. A new meteorological observatory is to be constructed in Constantinople.

Trade News.

TENDERS.

CATERHAM ASYLUM FOR IMBECILES.—Sir,—The tender of Mr. John T. Chappell—£83,677 has been accepted.—I am, &c., E. C. ALFLATT.

BIRKENHEAD.—For the erection of St. Ann's New Boys' Schools, Birkenhead:—

Fisher	£1320	0	0
Cameron	1311	7	0
Harkness and Dempsters	1309	0	0
Dobson	1259	8	9½
Black and Readie	1233	0	0
Forde	1170	0	0
Morris and Allen	1167	10	0
Bleakley	1165	0	0
Booth and Richards (accepted)	1150	0	0

BURSLEM.—For the erection of a flint mill, at Longport, for Mr. T. Hughes, earthenware manufacturer. Messrs. Scrivener and Son, architects, Hanley:—

Matthews	£2700	0	0
Beech	2725	0	0
Sidley	2710	10	6
Bowden	2685	0	0
Barlow (accepted)	2675	0	0
Blackhurst	2670	0	0
Wooldridge	2650	0	0
Woolrich	2620	0	0
Brindley and Critchlow	2580	0	0
Barley	2573	0	0
Bennett and Cooke	2490	0	0
Grosvenor	2460	0	0

CANTERBURY.—For the erection of a warehouse at Canterbury, for James Green, Esq. Mr. John Green Hall, architect:—

Epps	£3890
Dickenson and Company	3810
Sollit	3810
Wilson	3500
Gaskin and Company	3490
Adcock	3444
Naylar (accepted)	3385
Lawson	3389

CARDIFF.—For the erection of a warehouse, West Bute Dock, for Messrs. Adams Brothers. J. Hartland, architect. Quantities supplied:—

Shepton	£2294
Lock	2284
Seager (accepted)	2230

CHELMSFORD.—For additions to the Chelmsford Union House. Mr Charles Pertwee, architect:—

R. Choat and Son, Chelmsford		£557
W. Roper	,,	552
J. Baker	,,	550
T. Thorn	,,	540
G. Last	,,	470
W. Fincham (accepted)	,,	455

CHELMSFORD.—For heating and lighting Bocking Chapel. Mr. Charles Pertwee, architect:—

	Heating.	Lighting.
Harrison and Bettridge, Chelmsford	£115 0 0	... £46 10
Dennis and Scruby ,,	85 0 0	... 45 0
F. Christy ,,	66 12 6	... —
H. Farrow ,,	—	... 41 0
F. Critall (accepted) Braintree	87 18 6	... 21 18
J. Bloomfield ,,	—	... 45 0
T. Biggs ,,	—	... 29 10

FENTON.—For the erection of a smith's shop, at the North Staffordshire Engineering Company's foundry:—

Sutton	£397 15
Wooldridge	350 0
Matthews	297 0
Bradbury (accepted)	274 0

ILFORD.—For three shops and fifteen cottages at Ilford, for Miss Harvey. W. Allen Dixon, architect. Quantities supplied:—

Eaton and Chapman	£2985
Manley and Rogers	2975
Staines and Son	2448
Mann	2879
Garrad	2613
Withers	2495

LIVERPOOL.—For the erection of a dwelling house and livery stables for 22 horses in Hope street, Liverpool. Charles H. Belce, C.E., 22, Lord-street, Liverpool. Quantities by George L. Hunt, 19, Brunswick square, London:—

Wiley	£2100
Dixon and Sleight	1850
Nicholson and Eyre (accepted)	1639

LONDON.—For building No. 106, Fenchurch-street, and No. 62, Leadenhall street, for Messrs. Innes Brothers and Company, Mark-lane. A. B. Marsh, architect. Quantities by Mr. G. P. Raggett:—

Macey	£4856
Henshaw	4775
Carter	4600
Newman and Mann	4556
Foster	4529
Coleman	4500
Pritchard	4427
Myers	4389
Couder	4380
Brass	4093
Hill, Keddell, and Waldram (accepted)	4077

LONDON.—For the erection of five houses in St. George's-road, S., for Mr. Bedford. H. S. Legg, architect. Quantities supplied:—

	Amount of Contract.	Credit old materials.	Nett amount.
Ronald	£4955 ...	£150 ...	£4805
Raynham Brothers	4397 ...	150 ...	4247

Jones (accepted)	2865	2500	2347

SWINDON.—For new villa at Swindon. Mr. S. S. Lansdown, architect. Quantities supplied by the architect:—

Wooldridge	£808 15 0
Dover	750 0 0
Drew	745 3 9
Spreadbury	597 0 0
Selby	572 0 0

TUNSTALL.—For the erection of new store rooms, &c., at Johnson's brewery. Mr. R. Dain, architect, Burslem:—

Woolrych	£315 0
Blackhurst	305 15
Beach (accepted)	298 15

COMPETITIONS.

INDIA.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

HIGHGATE.—September 30.—For the erection of an infirmary at Highgate. J. Moore, clerk, vestryhall, St. Pancras.

LEAVESDEN WOODSIDE (near Watford).—September 30.—For the erection of schools. J. Moore, clerk, vestry hall, St. Pancras.

METROPOLITAN BOARD OF WORKS.—September 29.—For the erection of fire brigade stations at Amhurst-road, Hackney, and Upper Tooting. J. Pollard, clerk to the board, Spring Gardens.

PETERBOROUGH.—September 26.—For the erection of a new Baptist Chapel. J. W. Chapman, architect, 14, Great Western-terrace, Westbourne Park, London W.

TAUNTON (Somerset).—September 30.—For building a shop, with house and offices. Messrs. Giles and Robinson, architects, 7, Furnival's Inn, W.C.

SLOUGH.—September 30.—For the erection of two villas in Windsor road. F. Charsley, Herschels, Slough.

PORT MADOC (North Wales).—October 5.—For the excavation and building of quay wall. G. Lea, 54, Chancery-lane, London.

EATON (Norwich.)—For designs for new suburban church. Messrs. Hewitt and Capon, London and Norwich.

DERBY.—October 1.—For the erection of new hotel, &c., in Cornmarket and St. James-street. W. C. Watson, Company's offices, Wardwick, Derby.

WAR DEPARTMENT.—For raising the practice butt in Plumstead marshes. Capt. W. Mitchell, R.N., Royal Engineer office, Woolwich.

ST. PANCRAS (Middlesex).—September 30.—For the erection of infirmary for this parish at Watford, Herts. F. Moore, clerk to Guardians.

TUNBRIDGE WELLS LOCAL BOARD.—September 29.—For construction of outfall sewers, overflows, sewage tanks, &c. T. Elliott, clerk.

WITHAM LOCAL BOARD OF HEALTH.—October 1.—For the construction of sewers and waterworks.—J. H. Blood, clerk.

CHARTERED GAS COMPANY.—For purchase of breeze. J. Phillips, Horseferry road, Westminster.

ST. MARY, NEWINGTON.—October 2.—For painting the iron railing of the parish churchyard of St. Paul's, Walworth. Joseph Burgess, clerk to the board, Vestry Hall, Walworth, S. E.

GREAT WESTERN RAILWAY.—September 30.—For narrow gange carriage stock, first class and composite carriages, &c. F. G. Saunders, secretary, Paddington.

ST. MARY CRAY (Kent).—October 8.—For the erection of a new parsonage house. Mr. Christian, architect, 8A, Whitehall-place, London.

LONDON.—October 1.—For the erection of premises at the south-east corner of Gracechurch street and Fenchurch-street, City. Mr. Charles Baylis, 30, Poultry.

NORTH BERWICK.—October 3.—For the erection of coast guard station. Coast Guard Office, Somerset House.

ASKWITH.—For the erection of two good cottages, at Askwith, near Otley. William Edmondson, land agent, Denton, near Otley.

THAMES VALLEY LAND AND BUILDING SOCIETY.—Ashford Estate.—September 30.—For the construction of roads, &c. Messrs. Brewer and Son, architects and surveyors, 2, Upper Hill street, Richmond, S.W.

WEST DULWICH CONGREGATIONAL CHURCH.—September 30.—For the erection of a new school. J. Nicholls, architect, 8, Craig's-court, Charing Cross, S.W.

PROPERTY SALES.

SEPTEMBER 15.

AT THE MART.—By Messrs. Hards, Vaughan, and Leifchild. Freehold two houses and shops, Nos. 16 and 17, Park row, Trafalgar road East, Greenwich, let at £18 per annum—sold for £200.

Freehold piece of ground, with stable thereon, situate as above £400.

Freehold residence, No. 16, Park row, let at £45 per annum—£550.

Freehold residence, No. 15, Park row, let at £40 per annum—£490.

Freehold residence, No. 14, Park row, let at £40 per annum—£530.

Freehold residence, No. 21, Park row, let at £19 19s. per annum—£275.

Freehold residence, No. 22, Park row, let at £20 per annum—£275.

Freehold residence, No. 23, Park row, let at £20 per annum—£300.

Policy of assurance for £1,000, issued by the Provident Institution on the life of a lady aged 74 years—£300.

Contingent reversion of and in £3,000 Three per cent. Consols upon the decease of a lady and gentleman aged 43 and 39 years—£600.

Leasehold posting house, knowe as the Valley of Rocks Hotel, Lynton, Devon, with stabling, coachhouses, and premises, together with about 1¼ acres of land, term 1,000 years from 1680—£2,550.

Freehold 1 acre of land, situate as above, same term—£175.

Freehold 0a. 2r. 0p. of land, situate as above, same term—£80

Freehold 1 acre of land, situate as above, same term—£170.

Freehold 2a. 1r. 32p. of land, situate as above, same term—£220.

Leasehold improved ground rent of £14 15s. per annum, arising from 13 houses, situate in Hackney road and Nelson street, term 80 years, from 1807—£120.

Leasehold improved ground rent of £50 per annum, arising from 83 houses, in Hackney road, &c., term similar to above—£440.

Freehold house, No. 9, Burr street, Wapping, let on lease at £40 per annum—£550.

Freehold three acres of building land, situate in Crown lane, Fulham road—£2,400.

Leasehold business premises, No. 61, Queen street, Cannon street, annual value £750, term 14 years from 1868, at £395 per annum—£2,000.

By Mr. A. Hind.—Leasehold two houses, 1 and 2, Ebenezer cottages, Londonbrough road, Camberwell, producing £52 per annum, term 36 years unexpired, at £6 per annum—£450.

By Mr. E. White.—Freehold four houses, Nos. 30 to 33, Highbury vale, Islington, let on lease and producing £75 per annum—£1,200.

By Messrs. Norman and Son.—Leasehold messuage, No. 31, New North road, let at £42 per annum, term 62 years from 1824, at £5 5s. per annum—£290.

Leasehold business premises, No. 7, St. Ann's lane, City, term 99 years from 1772, at £20 per annum—£405.

Leasehold business premises, No. 111, Upper street, Islington, term 6 years unexpired, at £99 per annum—£83.

SEPTEMBER 17.

By Mr. Newbon.—Freehold residence, No. 15, Vorley villas, Junction road, Upper Holloway—£605.

Leasehold residence, No. 37, Barnsbury street, Upper street, Islington, let at £55 per annum, term 95 years from 1828, at £10 per annum—£590.

Leasehold four houses, Nos. 6, 11, 15, and 17, Albert street, Penton street, Islington, producing £136 per annum, term 99 years from 1848, at £24 per annum £1,270.

Leasehold house, No. 30, Brooksby street, Liverpool road, Islington, annual value £30, term 41 years unexpired, at £5 5s. per annum—£25.

Leasehold house, No 1, Wood-stock villas, Forest Lane, Stratford, annual value £26, term 77 years unexpired, at £4 per annum—£265.

BATH STONE OF BEST QUALITY.

RANDELL and SAUNDERS, Quarrymen and Stone Merchants, Bath. List of Prices at the Quarries and Depots; also Cost for Transit to any part of the United Kingdom, furnished on application to Bath Stone Office, Corsham, Wilts.—[ADVT.]

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

Charles Mills, Dockhead, Bermond ey, contractor, September 29, at 1—George Newton, jun., Brighton, builder, September 29, at 1.

TO SURRENDER IN THE COUNTRY.

Richard Allanson Harker, jun., Leadgate, Durham, joiner, October 5, at 10—William Murray, Pembroke Dock, builder, October 6, at 10—Frances Northall, Birmingham, gasfitter, October 9, at 10—George Steere Wakeham, Plymouth, mason, October 7, at 11—John Wale, Leicester, builder, October 12, at 10—Benjamin Earnshaw, Heanor, bricklayer, September 29, at 12—Charles Percival, Liverpool, paint manufacturer, September 29, at 11—George Viner Stent, Frome, carpenter, September 30, at 11.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

October 20, T. Hughes, Ponthlydden, builder—October 22, R. Hoad, South Shields, builder—October 20, W. A. M. and B. Mumby, Boston, engineers—October 20, R. Porter, Newcastle upon-Tyne, builder—December 1, I. Kerridge, Basnet grove, Wandsworth road, builder—December 3, R. Fitch, Dulwich, builder—December 3, J. Perigoe, Tunbridge Wells, builder—December 3, W. J. Birtchnell, Clapham Park road, builder—December 3, A. Bacon, Hornchurch, builder—October 30, W. J. Raker, Jubilee-street, Commercial road East, painter—November 4, E. Scally, Fitts-rents, Reeves-place, Hoxton, stonemason—October 6, W. T. Randall, Ramsgate, builder—October 6, H. Sparks, Exmouth, brickmaker—October 9, C. Noble, Bramham, builder.

PARTNERSHIPS DISSOLVED.

Rogers and Rawlings, Bradford on-Avon, stone merchants—The Saltburn Iron Stone Company—A. and J. Binns, Wakefield, builders—W. and R. Kirby, Leeds, builders—Hoyle and Morley, Greasbrough, builders—Howcroft and Atkinson, Gisborough, timber merchants—Hole and Cleminson, Watchet, engineers.

DIVIDENDS.

October 5, R. Shortridge, Plymouth, plumber—September 29, T. Everett, Dudley, contractor.

THE BUILDING NEWS.

LONDON, FRIDAY, OCTOBER 2, 1868.

WALKS WESTWARDS.

IN a recently concluded case, which has occupied a very large share of public attention, Mr. Ballantine observed that if an article was said simply to come from the East it might come from Wapping. So a walk westward may mean either a stroll from Temple Bar to the Marble Arch, or a journey on foot to the Land's End. If the reader will start in our company from Temple Bar, as from the meridian which divides the East from the West, we will proceed to notice what is being done in the building line. In short, he will receive the earliest possible impression of the "Building News." On the right hand is Wych-street, and at the west end of Wych-street is what was the Strand Hotel (very limited), but what is now the Globe Theatre. Is there not magic in the name? Shakspeare, Essex, Southampton, Sidney, and perchance Elizabeth's self. In about a month Mr. Sefton Parry hopes to open this theatre, and at that time an extended notice will be given. At present nothing is finished except the entrance in Newcastle-street. Mr. Parry is his own architect. May the Globe Theatre, if only for the name it bears, flourish long! Another theatre next presents itself as the only sign of building in the Strand, and it is a noteworthy fact that in the great western thoroughfares very little building is going on. The Strand Music Hall, disastrous alike to *impresario*, architect, and shareholders, is being converted into the "Gaiety Theatre," under the architectural supervision of Mr. J. C. Phipps. It will be opened in December. Besides this alteration nothing is being done in the Strand, and passing the graceful National Bank at Charing Cross, and the somewhat flaming Sun Fire Office, with its white marble, red granite, and red brick, we come to Her Majesty's Theatre. This building, under the magic hands of the Messrs. Trollope, has risen from its ashes in a surprising manner. It will be ready to open for the next season. Adjoining is Mr. Graves' house, partially damaged by the same calamity. A new roof has been put on, surmounted by much gilt iron cresting. And here the sacred precincts of Club-land are reached, and in the vaward stands that haunt of sages and philosophers, the Athenæum. Now it may be interesting to know that these sages and philosophers have found that they are limited in accommodation for their billiard playing, that their smoking rooms are inadequate, and that their servants require a hall, seeing that their present one is required for other purposes. These adjuncts are now in course of erection in the garden at the back of the club. Passing the elegant "Travellers" and matchless "Reform," a very imposing building occupies the right hand side, the sunny side, of the way. This is no less than the Junior Carlton Club, progressing under the superintendence of Mr. David Brandon, Messrs. Lucas being the contractors. £40,000 is supposed to cover the cost, but considering the vast size of the building, that sum seems insufficient. This building, vast as it is, is anything but an ornament to Pall Mall. Its three stories of ugliness are not redeemed by the fact that each story is 20ft. high, nor can coarseness of design be compensated for by polish of granite. It is unworthy of the site it occupies amongst its compeers. These remarks may seem harsh, but let any architecturally disposed person look at the needless crowuing balustrade and observe the manner in which the rail is carried down to a lower level; let him reconcile himself, if he can, to the topmost window openings, to the glittering granite columns of the first-floor windows, to the *pseudo* bow window between the western columns on the ground floor, to the thin ungraceful balusters, to the vile design and still worse execution of most of the ornament. If he can do so he had better leave us at once. The peripatetic method of teaching is, as regards architecture, excellent, but we care not to carry with us any who cannot see the grievous faults which disfigure the outside of the Junior Carlton Club. The ground-floor windows are well treated, however, and the front towards St. James's-square is not offensive. On this front the upper windows leave nothing to be desired, and why those facing Pall Mall were not exactly similar is a mystery. It is a mistake to divide this façade into centre and wings, and the carving of a shell over the central Venetian window is abominable, but the fenestration generally is good if not original. It is difficult to trace the same hand in these fronts. We make no doubt that the crowning balustrade, a most unnecessary feature, will be removed, and that the second-floor windows in the Pall Mall front will be altered to match those at the back. "A little charge will do it." A short distance further on will be seen an Elizabethan structure, consisting of a bay window of two stories supported by a massive corbel, the front terminating with a gable. This building is capable of considerable improvement; the style especially should be more pronounced, the corbel and buttress supporting it being too Gothic, while the mouldings and form of gable are too Jacobean to harmonise. It, however, supplies in a measure the thing that Pall Mall lacks, namely, picturesqueness. Leaving Pall Mall and turning into St. James's-street, and with averted eyes passing the old Thatched House Tavern, now the Civil Service Club—a notable instance of bad taste and good carving—we pause over against Mr. Waterhouse's University Club. About this building opinions vary. No one doubts Mr. Waterhouse's talent, but many question his application of it. The style is the perpetual French Gothic, which certain architects seem to keep ready on a roll of endless paper. Now, we have no wish to run down the middle ages, for without them there would have been no Waterhouse, no Seddon, no Street, no Scott, and, worst of all, no Barges; but it is impossible to forget that great works were done before the middle ages, and that still greater have been done since. Of the general features of this building many will be found to approve, but we cannot conceive that any will admire the little half sill, half balcony projections with their supports on the first floor of the bay. It is, moreover, indisputable that gurgoyles are for carrying off water, and for no other purpose. When we see them in connection with iron rain water pipes, which take off the water which the gurgoyles should discharge, however much we may admire the beautiful, we must allow that the true has been sacrificed.

Crossing the Park in the direction of Buckingham Gate we soon reach Grosvenor Gardens, an account of which was given in these pages about a year ago. Since that time considerable progress has been made. The block of nine houses, facing south-east, is completed, or on the point of completion, and the triangular space in front is enclosed with a substantial railing and stone piers of some pretensions, and is planted with lime trees. The National Bank, a corner building, is ready for occupancy. If less money had been spent on the supposed front of this building more would have been left to adorn the back, which is practically as conspicuous. The architect is Mr. P. C. Clarke. The terra cotta so freely used in the cornices and chimney caps of these houses has toned down from bright red to a very good red grey. Messrs. Blanchard and Co. are the manufacturers. The entire range of Grosvenor Place is nearly ready for occupation, the ceilings of many of the houses being of extreme elegance. An enormous house to the north is in a forward state, and five houses in the Crescent at the back of the hospital are carried up to the second floor.

Crossing the road great improvements since last year will be observed. The hoarding round the Park has given place to a granite curb and handsome iron railings with standards at intervals of about 10ft. The walk between the flower beds is pleasant still, as, though somewhat withered, the flowers or the leaves retain strong distinctions of colour. Park-lane is always picturesque, though there are few houses in it of what may be called architectural pretension. The exceptions are too well known to require notice. At the corner of Upper Brook-street a large building of four stories is in course of construction for Mr. Marjoribanks, from the designs of Mr. T. H. Wyatt; Mr. l'Anson is the contractor. This is a remarkable rather than a handsome building, and no donbt will be very stately in its interior. The entrance, which is at the eastern extremity in Brook-street, is adorned with four large columns of polished red granite. The west front consists of two bays carried up the full height of the building, with large triple windows or arcades in the centre. On the first floor it seems that this arcade is to be left open, forming a sort of *loggia*. At the back, rising above the roof, is a circular tower. The iron cresting is not what we should wish to see, and no amount of gilding or colour will improve it. Attached to this house, or rather connected with it by an underground passage, is the kitchen, with a billiard-room over, forming a sort of pavilion in the garden. This pavilion is a very pretty and quaint affair. The general material of the house is red brick, with stone dressings, and at present the contrast is too strong. Against polished granite and marbles we have always protested, and regret to see them used here. If, however, they are ever justifiable, it is in a case like this, where red brick forms the chief element in the colour of the house. Nearer the Marble Arch, on the spot where Hereford-street once stood, Messrs. Trollope and Sons are putting up a row of eleven large houses, similar to those at Grosvenor Gardens, the ground being the property of the Marquis of Westminster. Five of these are nearly finished. The space between Oxford-street and these houses will be left open and planted ornamentally. In New Bond-street (No. 90), Mr. Wimperis, of Sackville-street, has designed a very quaint front, which is well worthy of inspection. The materials are not varied like a harlequin's suit. Yellow brick and Bath stone will, in skilful hands, go a long way. The way in which the roof is made into an upper story is very ingenious. And now, as we are near the Circus, and have seen nearly all that is going on at the West End, within a moderate circuit, we will take leave of our companion, hoping for his company for a walk still farther westward on another occasion.

SYMBOLISM.—III.

THE excesses of symbolism in ecclesiastical architecture have often given birth to a cry against symbolism itself. The bare four walls of the Puritanic tabernacle, and the equally bare ceremonial within them, have been amongst the results. But even to those who, on grounds of conscience, tacitly submit to such violations of taste, a sense of dissatisfaction is present, as if something were lacking. The fact is that in all human life symbolism takes its place, and it cannot be altogether eliminated from the ecclesiastical any more than from other departments of thought and interest without loss. The principle is founded in nature, and its development in ecclesiastical life is not the fruit of superstition, nor need it conduce thereto.

In one form or other symbolism has held sway in human society to a far greater extent than is usually conceived. Indeed, hardly a phase of mental action, or of social or even political life exists, but in some of its subtle operations this principle is called into play. A prime fact in human history is language; but all speech is made up of mere symbols of thoughts, and all written language is made up of symbolic signs of the sounds of speech. In an immense proportion of human speech words are perfectly arbitrary signs of mental action; for, to take examples, what resemblance have the vocables "human speech" and "mental action" to the *things* thereby signified? and what resemblance have the alphabetic characters forming those vocables to the *sounds* they serve to represent? But this absence of resemblance is not always witnessed. Every language has sounds which tally wonderfully with the things they name. Follow the stream of human speech towards its source. Examine the tiny rivulets, its first tributaries, trickling down from those regions where man's presence is first witnessed by history and the most ancient monuments, and you receive the conviction that many of the earliest articulations of the human tongue were meant to be *imitative* as well as representative; that is, they were meant to be not merely signs of objects or ideas, but significant signs, suggested by some chief characteristics of such objects or ideas. For example, sounds were chosen as names of creatures, corresponding with the cry or the nature of the animal, and when simple thought or emotion was indicated, the sound chosen was soft or sharp, strong or weak, to correspond. Thus the lowing of the ox is imitated in his name in many languages, as in the Greek *βοῦς* and the Celtic *buwch*. Instances innumerable might be cited of names of animals given on this principle in all the older tongues. And how often in the newer materials of speech do we find this same symbolic practice prevailing! The "hum" of a crowd, the "crash" of a falling house, the "gurgling" of a liquid, the "cooing" of a dove; and such words as smack, whisk, clack, whistle, slap, thump, bang, shriek, are examples of imitative vocables which form a wide element in every language. Indeed, animals themselves seem not devoid of power to symbolise emotion by articulation. They have shrill cries of distress, and sweet tones of joy and love. The dog has a variety of barks, all indicative, even to our apprehension, of a corresponding variety of feeling.

Symbolism is largely practised in human gesture. There is scarcely a phase of emotion but flows forth in it. Even the expression of the countenance is a natural and universal herald to the outer world of what passes within; and is capable, by power of will and habit, of reduction into a system of telegraphy whereby a vast variety of mental states can be indicated, concealed, or simulated at pleasure. In oratory, when speech is accompanied by natural action and expression, a three-fold system of symbolism is practised at once, and this is the reason why the same sentiments, when well spoken, are so much more effective than when read.

Men of all nations have learned to make the covering of the body symbolic. The burgomaster, the notary public, the beadle, has half his authority in his gown. The priest, the field marshal, the king, is a common man without cassock, gold lace, and diadem. The Herald Office separates society into sections and orders by a few devices which form permanent and impassable barriers. On the table of St. Stephen's the mace tells of the power and kingship of the realm. There is scarcely a guild or craft which portrays not its purpose and nature in some symbolic invention. If it be a weakness that is thus indulged, nations have it as well as Odd Fellows' clubs. Whatever the first reason of the adoption of the Union Jack, and whatever "Jack" in such a connection may mean, the whole world knows the significance and inviolable sacredness of that flag in whatever clime it floats. *La Grande Nation* is an "eagle." The Great Republic is "stars and stripes."

And all this is not the invention of learning, or a formula of civilisation. It is a creature of the human mind in all stages of development, under all conditions of creed, nationality, and climate. The savage with his tattooing and feathers proclaims his rank with a care neither greater nor less than that of a coronetted English duke or capped Venetian doge. Symbolism in dress, official emblems, and armorial bearings is a beautiful language, suited to give information respecting facts which it is desirable to know, without the intervention of description.

The clerical vestments, after which the weak and feminine-minded are in our day so eagerly running, have in them but little that is symbolical. For the most part they are in reality but copies of articles of common dress worn by the Romans, and worn as a matter of course by the early christians, whether clergy or not clergy. They are, therefore, in themselves, not worth contending for in an age and country in which costume of a different kind is in use; and the partiality shown for them seems to arise almost entirely from their antiquarian and their mediæval doctrinal associations.

Light and darkness, day and night, summer and winter, and all the phenomena of nature have been seized upon by the poet to portray the varying aspects of human fortune and feeling. The "light of the dwelling," the "night of sorrow," the "winter of discontent," the "autumn of life," embody in brief more than long chapters of description. And in symbolism the colours which are felt most to resemble light, and gloom, and darkness, are largely used. We speak of what is "bright" in feeling and circumstance, and body it forth accordingly to the eye. Hymen's altar is approached in white; the sorrow of the mourner is typified in black. No colour is dark enough to stand for despair.

If this passion for instructive resemblances and bodying forth in material form the invisible, which mankind has universally betrayed, were wholly absent from any department of human doings, even the most prosaic and matter of fact, we should say that something was wanting, and that the free flow and play of feeling and imagination had been violently impeded. No such department is found. From the imperial sceptre to the barber's staff—through all ranks and descriptions of privilege and employment—men seek for and find a symbol of their status and distinction. Great interests, great hopes, are all represented. The market hall is decorated by the Cornucopia; over the judge's seat stands the figure of even-balancing justice; the Cemetery-gate is surmounted with the burning lamp of immortality; and the church is crowned with the cross. All such symbols are for use and not for abuse; they are monitors and witnesses to those who understand, and teachers to those who learn.

Erections for shelter, or for assembly, are amongst the greatest and most universal of human works, and, as might be expected, are found to display to some considerable extent the use of symbolism. At the same time it is somewhat remarkable that when man came to exchange the shelter of the cave, the over-canopying oak and the forest, and the grander dome covering of the starry heavens for substitutes built of wood or stone, he did not scheme his first designs in a manner to embody more of nature's features. Or if it be not a cause of wonder that with a necessarily imperfect knowledge of art he did not accomplish this, it is at least cause of no surprise that in the noontide of classic art frequent and elaborate endeavours were made to garnish the villa, the triumphal arch, and the temple with emblems of natural and supernatural things.

NOTES IN CHESTER.

THE picturesque and old-world capital of Cheshire does not present, by any means, those indications of architectural progress and activity which a visit to the town some years ago might have led us to expect. Chester always seemed, to the visitor reaching it from any of our large manufacturing or commercial towns, a place fifty years behind the rest of the world—a place of odd nooks and angles, overhanging gables and eccentric skylines; where houses stood propped together in a marvellous manner, at any angle but a vertical one, a whole street looking as if it must inevitably come down by the run if the end house were once removed—a place where those who were tired of the incessant bustle of a "go-ahead" town could indulge in a little quiet sauntering, and, once out of the sight and sound of the railway station, fancy themselves for a moment in the England of the last generation; a fancy to which, unhappily, an additional reality was lent by the bad smells and dirty alleys which told plainly of a drainage system as antiquated in spirit as the aspect of the buildings. It would be far from us to wish that all the ancient character of this and some other similar localities should be eliminated. It is a pity to lose any of the few remaining links which seem to connect us with the past of our country, and assist us to realise it; but such feelings must give way to some extent before practical and sanitary considerations; and, considering the many evils attendant upon narrow and low rooms, and bulging and leaning tenements crowded together in picturesque confusion, it was with satisfaction that we observed in Chester, some years ago, an apparent stirring among the dry bones, a removal of "sagging" brestsummers and leaning story-posts, in favour of some new erections, in which an attempt was evidently made to combine the old picturesque style of the place with firm and solid modern construction. This effort was mainly observable in sundry new shop fronts in Eastgate-row, two or three in the old half-timber fashion of the place, and one, the large establishment of Messrs. Brown, a stone front of picturesque general design, but bad and weak details, the work of the late Mr. Penson, who enjoyed considerable local reputation as an architect. At the same period it was that the new bank, with its orthodox Roman temple front, swaggered into Eastgate-street with its hands in its pockets (so to speak), domineering over the slighter and more picturesque buildings adjoining, with an air which rendered all questioning as to "Which is the bank?" perfectly superfluous. But from whatever cause—whether it be that the commercial stagnation which has checked building so much in Liverpool and elsewhere, has also made its influence felt in the non-commercial town of Chester, we know not—the promise given at that time has not been fulfilled; and, with the exception of the new Townhall, the visitor of to-day finds no building of any interest in progress, and the aspect of the streets and rows little altered from what he may have remembered for a good many years back.

The general effect of the townhall, the tower of which is now well clear of the roofs, is very satisfactory. There is a depth of reveal in the openings and a general solidity of design in the details which evince the true architectural spirit in its designers; and, for *present* effect, the selection of the two tints of stone for the masonry, the white or cream coloured stone from Manly, with bands and alternate voussoirs of red Runcorn stone, is singularly harmonious and pleasing. The only question is whether the contrast of colour is strong enough to retain its effect long against the action of weather, constantly tending to bring it to a uniform tint. It appears to us that these sources of effect from contrast of external material cannot be expected to last long unless they are at first made rather too strong and decided, and allowance thus made for the

action of a climate so trying to architectural effect as that of England. The surface finish of the walling, scutched rather lightly so as to produce just sufficient roughness to give a texture to the stone, is very good; and the Irish marble from Ballinasloe, which has been largely used for shafts, &c., seems a very good material, and harmonises well with the stonework. Internally the finish of the corridors, so far as is yet apparent, is of red brick, not quite so good in quality as brick in such a position should be; but this is, perhaps, a question of funds. Opposite the entrance a vista right across the building will be obtained, the centre portion being left open as a kind of general waiting hall, and crossed by a very picturesque bit of semi-circular staircase leading to the mayor's private room. The large hall is a good open room, well lighted, but with nothing very striking about it so far, and the roof is a poor and ineffective one. Externally, we dislike also the open balustrade round the roofs, a row of miniature columns carrying little pointed arches, which on that small scale have a disagreeably thin and slight appearance. It does not seem to be sufficiently recognised among architects that a proportion of parts which looks well on a large scale will often look very meagre on a small scale, and the use of either miniature shafts and arches or miniature columns (as we have seen them over the cornice of a classical building), with the same proportions as when used the ordinary size, always has a card-house kind of effect. The one real invention of the Renaissance style, the balustrade, is an admirable instance of the correct treatment of these kind of small parts; the heavy round lines of the balusters would be hideous on a large scale, but as generally used they have just the amount of weight and thickness which so small a feature needs to give it due solidity and importance. This is, however, the only positive defect which strikes us in the exterior of this building; as townhalls go, Chester is certainly fortunate, and the building looks all the better by contrast with the hideously ugly front of the market adjoining, erected some little time since from the designs of a Liverpool firm who have done much better things, but of whom, in this instance, we may say, in the old nursery rhyme—

> We do not like to tell their name,
> Because they are so much to blame.

It is to be regretted that the small space between the market and the townhall is disfigured by the retention there of two shops, part of the old buildings on the site, of the most wretched hole-in-the-wall style; and that a design submitted by Mr. Lynn for replacing these by a picturesque gateway and small loggia connecting the two buildings has been, so far as we can learn, discarded. There have been heart-burnings, too, about the application of some of the townhall building fund to sculptured subjects for the tympana and panels, &c., in the interior of the building; let us hope that art considerations may happily prevail over those of the pocket.

In Bridge-street-row is the largest and most important of the more recent rebuildings of shops in Chester, designed, but not we believe carried out, by the late Mr. Penson, aforesaid, who also designed the large hotel in Eastgate-street, the "Grosvenor," which has been so ridiculously praised, and which is about as weak and unsatisfactory a design as could well be instanced; nor are these bridge shops much improvement thereupon. *De mortuis nil nisi bonum* is a rule that we fear must not be allowed to hold good in art criticisms; and in these buildings we are struck by the poverty both of design and construction displayed. The first floor of course projects over to the front of the "Row," the front wall above this being carried by stone piers in the ground story. These piers carry wooden brest-summers, which are pretended to be further supported by ornamental angle brackets from each pier to the soffit of the brestsummer; but not only are these brackets so slight as to be evidently inadequate for any practical purpose, but even the brest-summers themselves are too weak for their work, and are already visibly bending under the load of brickwork over them, and this with all the warning examples which the architect had before his eyes of the twisted, distorted shapes into which all erections ultimately fall which depend upon timber of insufficient scantling. Above there is an expanse of brickwork in panels of *rouge et noir*, pierced by isolated window openings without any horizontal band or stringcourse to give connection and unity to the design. A very plain and unpretending shop front in Foregate-street, by Mr. T. M. Lockwood, is quite a relief after these, owing to the evident strength and solidity of the beams, corbels, and piers which carry the overhanging portion, and which are effectively treated, though the ornament is derived only from chamfering and from the outline of the corbels. Mr. Douglas, a local architect (formerly, we believe, a pupil of Mr. Paley, of Lancaster), has a new shop by the bank in Eastgate-street, very weakly and poorly treated in front, the upper story merely an oblong window in the centre of squares of timber and plaster. There is some good solid brickwork at the side and in the chimney stacks; but the system of cutting away half of the stone lintels to make a sort of *quasi* flat-headed arch out of one stone is a most inarchitectural and really absurd practice, involving simply the cutting to waste of nearly half the material. As a general rule, architectural design, in proportion as it is good and true, is conservative of material, using it in the least wasteful manner possible. Mr. Douglas has, however, redeemed his credit in the lodge he has built for what is called the "New Park," presented to the city by the Marquis of Westminster; which at present, however, is little more than a large lawn. The lodge is a very pretty thing indeed, built in timber and cement; part of the cement between the timber covered with an incised or stamped diaper ornament with good effect; while the principal vertical timbers, above the first floor level, are carved into Gothic figures of knights in armour, possibly intended to represent some ancient Cestrian worthies. There is a good deal of other ornamental wood carving, good in design and execution. It is a pity that the porch, which of course is nearest the eye, should be so much more heavy and clumsy in design and detail than the rest, and picked out with that meagre and helpless sort of decoration which consists in boring holes with a centre-bit in different parts of the timber. Behind the lodge proper are retiring-rooms for ladies and gentlemen (an accessory which should always be provided in any park which may be used as a place of public amusement). The form of the window-heads to the ladies' apartment is too *outré* and cut up; but, in the main, it is a very pleasing design; and we hope, for the sake of its architect, that he did not design the very unsightly piers of the lodge gates adjoining.

In a street out of Eastgate-street is a Welsh chapel, with a solid Gothic stone front and porch, by the Messrs. Audsley, of Liverpool—the details better than the general effect. At the Cathedral, which is now at last to be refaced, restored, and "made good" generally (to use a builder's phrase), there appears, so far as we could ascertain, to be nothing done yet in the way of absolutely replacing or repairing the stonework, but a large amount of stone is on the ground and in a state of preparation. The restoration has certainly not been commenced too soon, for doubts might reasonably have been felt as to whether the old weather-beaten structure would have been safe much longer, so much was the stone decayed, and so serious were the deviations from the perpendicular in many parts. The nave is fitted up with benches and chairs for the Sunday evening services in a manner sadly detrimental to its architectural effect, but which is, we suppose, a necessary consequence of the effort that has been recently made to put new life and popular interest into the cathedral system. For those who are interested in such matters it may be noted that the frequenters of the cathedral are indebted to the present Dean for having introduced a fully intoned service, thus rendering complete and uniform in its effect what was formerly, at this Cathedral, a medley of intoning on the part of the choir and speaking on that of the officiating minister. Let anyone who visits Chester cathedral enter it by the dark vaulted passage leading into the east side of the cloister adjoining the chapter-house; the sunlight seen at the end of the passage, falling through the broken cloister window and on the green foliage beyond it, is as charming a bit of effect as one often sees.

Looking to what may be done in the way of future architectural improvements at Chester, we should recommend that while every attention be paid to the character of the surrounding streets and buildings, and the *genius loci* generally, as influencing the style of a new design, that nevertheless the half-timbered style of the old houses should *not* be adopted in future erections. Picturesque effect can be obtained from this style, no doubt, but it is scarcely architectural effect; and no care can make it as solid and durable as stone and brick, while the danger from fire is of course very much greater. The effects of a fire in Eastgate-street at present would be disastrous; it would be almost impossible to stop it. And there is no reason why the charming effect of *chiaroscuro* obtained by the open ground story, with the "Row" passage-way behind it, should not be made quite as piquant and effective with stone piers or granite columns and arches as with story-posts and lintels; indeed, much more so. Nor need the design be confined to the pointed arch style. The round arch arcade gives more light, and can be made as graceful and picturesque as a pointed arcade; and that even in the "classical" style, if desired. It is too late to introduce this feature into our newer towns, where all the front ground floor is already occupied as valuable land; but whenever the time comes (and it ought to come pretty soon) for extensive rebuilding of the Chester Rows, the inhabitants of the old city will have an opportunity before them for securing an architectural effect in their streets superior to what any other town in England can now boast. It will be for them to see that this opportunity is not thrown away; that the work is entrusted to really good and competent architects; and that it is carried out in such a manner as to prove a lasting and enduring construction, and not fall into such strange defiance of all perpendicular and horizontal lines as is exhibited in the present remains of Old Chester.

ESTIMATE AND PRICE BOOKS.*

IT is a common objection to all compilations, whether their contents assume the form of pocket-books, manuals, estimate or price books, that they fail to supply data for particular examples. One is inclined to imagine that their resources should be exhaustless, and one becomes disappointed if upon reference a single item that may be required is not found to be included. This is expecting too much from any compilation. While every effort should be made to render the contents as universal and comprehensive as possible, still it would be manifestly impossible to afford information upon every point connected with the various branches of the architect's and engineer's profession. In the volume under notice, the Messrs. Atchley have launched out in a line somewhat novel,

* "Atchley's Civil Engineer's and Contractor's Price-book for Home and Foreign Service." By W. Davis Haskoll, C.E. To which is added "The Law of Contracts, &c." By W. C. Glen, Barrister at-Law. London: Atchley and Co., Engineering and Architectural Publishers, 106, Great Russell-street, Bedford-square.

and introduced a price-book possessing many distinguishing features in comparison with other volumes of a similar character. The work is professedly adapted for the use of the civil engineer and contractor, and is, therefore, based upon a foundation differing in many respects from that constituting the groundwork of other books of a like description that are more particularly suitable for the architect and builder.

In the chapter alluding to tunnel estimates, the author selects a couple of examples which he mentions "may almost be taken as instances of a minimum and maximum of cost of tunnel work." The instances selected are the Lydgate tunnel and the Buckhorn; the former being situated upon the line of the London and North-Western Railway, and the latter upon the Salisbury and Yeovil line. The average cost of the former per lineal yard was £30, and of the latter £72. In these two estimates the average was calculated from a mean of the cost of those lengths where lining was required, and also where it was not needed. In the latter, the contingency of water was included, as a large quantity was encountered and had to be dealt with accordingly. Let us now take some other instances of tunnelling, and by comparison check the statement put forward in the volume under review. The following instances are in every way fair comparisons, as the circumstances under which they were constructed were precisely similar to those selected by the author. Were they not so, the remark "minimum and maximum" would be equally incorrect. The Kilsby tunnel, situated upon the London and North-Western Railway, cost £130 per lineal yard; the well-known Box tunnel, on the Great Western line, and carried for a portion of its length through an oolitic formation, exceeded £100 per yard run. Perhaps one of the best examples illustrative of the uncertainty of tunnel estimates is afforded by the Bletchingley and Saltwood tunnels, both of which are works upon the South-Eastern Railway. Their cost per lineal yard was respectively £72 and £118. In the face of these facts, an engineer who based his estimates upon the data supplied in the "Civil Engineer's and Contractor's Price-book," might discover, when the work came to be executed, that his calculations were erroneous, and would have to submit to the mortifying reflection that he had involved the company in an expenditure which had not been anticipated or provided for. Evidently £30 and £72 per lineal yard cannot be fairly assumed as the "minimum and maximum of cost for tunnel work."

The title "foreign service," implying that the "price-book" is available for the preparation of estimates of works intended to be constructed abroad, appears rather a misnomer, since the only portion of the text bearing out the appellation is that relating to "East Indian railway prices." How far these prices would be of the least utility in estimating for engineering works in the Cape, the West Indies, Canada, or on the Continent we must leave our readers to determine. We would only remark that it is one thing to adopt a comprehensive title and another to practically illustrate it in the context. The distinguishing feature of Messrs. Atchley's new production is the incorporation of several specifications in the body of the volume, together with Mr. Glen's treatise upon the "Law of Contracts." It is questionable whether the introduction of these addenda, which must be acknowledged to be somewhat germane to the real character of the book, serves any other purpose than to swell its contents and raise its price to an amount far beyond what is usually paid for a work of a similar description. The few pages devoted to "Contractor's Plant and Tools" are of a very valuable character, as it frequently occurs that no reliable information can be obtained respecting these particular items, which are of the greatest importance to anyone requiring their aid in the execution of works. In the preface to this part of the work there appears a little slip. It is stated "we are no advocates for anything that is *cheap* merely because it is *bad*." We should not suppose anyone ever was; the passage should run, "we are no advocates for anything that is *bad* merely because it is *cheap*." A person acting upon the motto "penny wise and pound foolish" will often purchase a bad thing simply because it happens to be cheap, but we confess we never heard of anyone purchasing a cheap thing because it was bad. This is putting the cart before the horse with a vengeance. The Messrs. Atchley, as well-known publishers, ought thoroughly to understand the "art of book making," and we will, therefore, not comment upon the questionable propriety of introducing advertisement pages in the very middle of the volume. The type is bold and clear, and the figuring distinct, two very essential features in all books of reference, since one wishes to find what they require at once without the necessity of reading an adjoining page of the context. It is a pity the same principle of clear and distinct lettering and figuring was not adopted in the half-dozen plates attached to the work. As it is, the letters and figures are scarcely discernible without the aid of a microscope. The "Civil Engineer's and Contractor's Price Book" is a larger and more pretentious volume than any of its predecessors, and, therefore, naturally is published at a higher price. For the engineer and contractor it certainly supplies items and details not to be found in other books of the same kind, but the architect and builder will find their wants better supplied in "Laxton" and "Lockwood's Builder's and Contractor's Price-book for 1868."

THE NEW MIDLAND RAILWAY STATION, ST. PANCRAS.

THE completion of the Midland Railway Company's new line from London to Bedford, although announced some time since, was only yesterday brought into requisition in its entirety. Hitherto the company has had no London passenger station of its own, all its traffic running into and out of the Great Northern Company's station at King's Cross, to the great inconvenience of both companies. The new Midland station opened yesterday is almost immediately contiguous to the King's Cross station, having a frontage to the Euston-road; or, rather, we should say that the new terminus hotel, not yet completed, will front the Euston-road, the station being behind the hotel, as at Cannon-street and Charing Cross. Like those of the latter stations, the roof will be in one span, only a much wider one. This roof is 700ft. long, 100ft. high, and 240ft. in width. Its crown is glazed to the depth of about a third of the space from the ridge to the eaves throughout its entire length, but the dark chocolate colour with which the ironwork is painted greatly subdues what would otherwise be a very brilliant effect. The boarding of the unglazed sections of the roof is coloured French grey. A somewhat novel mode of construction has been adopted. Instead of erecting massive walls for the support of the roof it is made to spring directly from the ground, the spaces between the ribs (which are twenty-five in number) being walled up so as to present the appearance of a wall supporting the principals of the roof. The ribs of the roof are not semi-circular, but on the model of the "drop arch." The feet of these ribs rest on a thick bed of concrete laid on the London clay, and are kept in position by means of iron shoes, each weighing 4½ tons. Massive tie girders beneath the floor of the station impart great rigidity to the roof principals, and further security is afforded by the use of tremendous iron bolts, 24ft. long, and 4in. in diameter, which pass through the piers on which the principals rest and are fastened by huge nuts to anchor plates below. Great strength is by these means secured, and the forest of ties, beams, and supports so common to many of our large roofs are dispensed with. The weight of each main rib is 50 tons. A mammoth travelling scaffold was brought into requisition for the erection of the roof. It was 100ft. high, 240ft. wide, and 30ft. in depth, and some hundreds of tons of timber were used in its construction. It travelled upon several lines of rails, going forward as the roof was completed, and it was fitted up with workshops, forges, cranes, &c. The new station not being on the ground level, as is the King's Cross Station, but on arches, inclined approach roadways have had to be made for vehicles. The hotel is not yet built. Flanking each side of the enormous structure is a row of picturesque shops and other buildings. The platforms have edges of dressed stone, and are floored with red deal planks, dressed, close jointed, and tongued with hoop iron. The planks are laid crossways, and spiked to wall-plates laid upon brick walls built upon the buckle-plates. There are four platforms and a carriage road, and eleven lines of rails, with room for two more. Excepting one along one wall of the station, the platforms are available at both edges. A tesselated frieze, about 2ft. deep, is being inlaid with Minton's coloured tiles. The moulding above the frieze will be surmounted by an iron cresting of floral design, the leaves to curve inwards from the cornice. The face principal at the entrance to the station is a fine piece of ironwork, and presents a commanding appearance, the effect being much enhanced by the cresting round the end of the roof, with pinnacle at the apex. The side walls are finished by a projecting base of Nottingham red brick, returned round the feet of the principals with Staffordshire blue bricks, and capped by a massive moulding of red Mansfield stone. On Saturday and Monday last Colonel Hutchison, of the Railway Department of the Board of Trade, was engaged in inspecting and testing the bridges, the roof, and other portions of the works. The results were highly satisfactory. A great deal yet remains to be done in the station, and only a comparatively small portion of it can yet be made available for the business of the line. Fully two months must elapse before the station proper can be said to be completed. In the construction of the station 9,000 tons of iron, 60,000,000 of bricks, 80,000 cubic feet of dressed stone, and many thousand feet of glass and timber have been used. The general style is a modification of Gothic to the requirements of railway architecture, the architect being Mr. George Gilbert Scott. When completed, the station will be lighted by sixty small sun-burners suspended from the roof and protected by glass, and having a brilliant effect. The lighting arrangements have been entrusted to Messrs. Sim and Barff, of Parliament-street, to whose patent hydro-carbon process is attributable the brilliancy of effect referred to, while a saving of 60 per cent. is said to be effected. Underneath the station and level with the Euston road is what may be called an enormous "hall of columns," which will be devoted to the storage of goods. The floor of the station is supported by these columns, which are 600 in number, placed at intervals of 14ft. 6in., and resting on piers having their foundation on the London clay. Below this "hall of columns" run the Fleet sewer and a branch of the underground railway.

BIRD'S PROCESS OF SEWAGE DISINFECTION.

THE *Lancet* gives an account of another new method of disinfecting sewage which is now in operation at Stroud, Gloucestershire. The works at Stroud were originally constructed for a lime process, differing materially from that which is now employed. The disinfecting agent is a sulphate of alumina and iron, obtained by treating a ferruginous clay with sulphuric acid, and then drying and pulverising the result. The stream of sewage, on arriving at the works, is made to turn an immersed wheel by the force of the current. Above this wheel is a hopper, by which the "sulphated clay" powder is suffered to fall into the sewage at a definite rate, and the wheel mixes it thoroughly with the liquid, which then passes on into a large tank. In this tank a certain degree of separation takes place. The heavier portions of the sewage subside quickly, carried down by the fall of the clay. The lighter portions—hair, feathers, fat, and other substances—float on the surface, and are removed by skimming. The middle stratum of the liquid is, therefore, comparatively clear; and an outlet is provided at about half the depth of the tank by which this middle stratum is suffered to escape at the same rate as that of the admission of sewage. The escaping middle current receives from another hopper a second dose of sulphated clay, and then passes into a second tank. From this it ascends through a charcoal filtering bed to a third tank, and from the third tank through a similar bed to a fourth. From the fourth it

escapes as "outfall water," and is suffered to pass into a neighbouring stream. The tanks in which this process are carried on are arranged in two parallel lines, each line containing a complete series. The inlet is so placed that the entering stream of sewage can be turned into either series at pleasure, and thus, as soon as a sufficient quantity of deposit has accumulated in one set, the sewage is diverted into the other, and the first set is emptied for cleansing. The deposit thus obtained and the skimming of the first tank are spread out upon drying beds and covered with a thin layer of the sulphated clay powder. When sufficiently dry the whole is collected, and forms the basis of a manure that is compounded and sold at £8 per ton. The works at Stroud may be fairly said to be free from offence. Mr. Bazalgette, who lately visited them, says:—"The processes of deodorising and manufacturing the manure cause no nuisance, and may be carried on in the immediate neighbourhood of dwellings." The only period at which any smell is given off is during the short time occupied in cleansing the tanks. The outfall water as it escapes from the last tank to flow into the stream is free from anything unpleasant to the senses. It has a slight yellowish-brown colour, due to suspended oxide of iron, and is free from odour. Analyses made of the sewage and the outfall water show that the sewage before treatment contains 53·25 grains per gallon of dissolved and suspended matter, among which there are 2·48 grains of ammonia and 1·506 of phosphoric acid. The outfall water contains only 0·560 grains of ammonia and 0·063 grains of phosphoric acid. It may be inferred, therefore, that four-fifths of the ammonia have been completely oxidised, and that 24-25ths of the phosphoric acid have been thrown down.

OUR ARCHITECTURE.

UNDER the above title a writer in the September number of "St. Pauls" comments at some length on the general adoption of Gothic by the architects of the present day. His ideas, summed up in a few words, are—that it is absurd to speak of Gothic as "English architecture," architecture being, as he contends, a thing of period and not of nations; that the style of architecture which admirably suited the want of the fifteenth century is altogether unfit for the nineteenth. We reproduce some of his arguments for the especial benefit of our Gothic readers.

"Let us," he says, "for a moment consider the influence which the single material, glass, would naturally have upon building. Anciently, in the beautiful climate of southern Europe,—probably then even more genial than now, because the land was better cultivated, and where glass was as a building material practically unknown,—the light and air required were generally admitted freely from the top; but where openings in the walls were used they were in character like those of our modern houses. But in the north, to keep out the weather by a substantial roof was a first necessity; and for a like reason, and for security from violence, the window openings were made very small. When glass became more easily procurable, light could be admitted without the probable accompaniment of rain and wind, and the size of the openings was increased; but as glass was precious, and in the leaden frames in which it was mounted was liable to damage if the openings were large, the plan was invented of subdividing one large opening into several smaller ones, which, woven and interlaced in the upper part of the openings, became, under the name of tracery, one of the crowning glories of the Pointed styles. The mediæval artists, giving free play to their fancy in the devising of an endless variety of graceful forms, converted, by the means by which it was surmounted, what was really an obstacle into a source of beauty. But with the costliness of glass passed away for ever the necessity for tracery; and now, as ever since, its use is a mockery and a sham. Let any one consider whether in a building in which plenty of light is required—and in what modern building is it not?—he would take away, as by the use of tracery he must, a great portion of the upper and therefore the most light-affording part of his window openings. There can be but one answer; except, perhaps, from a professed Gothicist."

"Must we," he asks, "for ever be mere imitators of the past? must we for ever see Corinthian and Ionic, First-pointed and Second-pointed, Italian and Renaissance, Romanesque and Byzantine? Certainly it seems proved that if we depended upon an eleven of gentlemen in good practice, we should have to do so. But surely we may hope for better things. There are signs in this very city, in even some of the warehouses and like buildings, that a sounder knowledge of the principles of taste is growing up. A palace of justice, or a national gallery, is a higher flight, it is true; but if the intelligence of the kingdom be asked to essay its powers, it may well be expected that far worthier designs will be produced than any of those by the chosen few. All England against 'The Eleven' is all the world to nothing."

He concludes with a humorous sketch of the sorrows of a poor antiquary or archæologist who a few hundred years hence shall discover, "say, far north in Scotland, a church early Norman in style. How his eyes sparkle! Nothing was known of the Normans having penetrated here. He has made a discovery; he will throw a new light upon history. The style is something feeble, it is true; but it is clearly of about 1100 A.D. Then the stone comes from a quarry many miles off, and in a spot which clearly must have been inaccessible to wheels before the present road was made. This proves that the road must have been in existence before 1100. Wonderful race, the Normans! Again he finds in the work some characteristic previously supposed to have been introduced about the time of Victoria I., or Edward VII.; and he thinks, with Alphonse Karr, that, after all, inventions are only things that the world has had time to forget. So he muses and moralises, and goes on peering among the mouldering stones until at last he comes to the foundation, where he finds a glass bottle which, more elated than ever, he pounces upon, and, opening it, learns that the first stone of this church was laid in the year 1868."

FRENCH UPHOLSTERY.

THE raw materials used in the manufacture of fabrics for upholstery are very numerous. The organzines of France and Piedmont, the wefts of China and Japan, are used in the manufacture of the silk fabrics. The price of these materials has much increased during the last few years. It is now at 120fr. to 130fr. for the warp, and 110fr. to 120fr. for the weft. The French silk is the dearest and most esteemed. The manufacture of reps and table cloths is composed of French wool, valued at 10fr. to 15fr. the kilogramme, and floss silk, worth from 40fr. to 60fr., which is chiefly derived from Switzerland. Utrecht velvet is made of goats' hair, spun in England, and sold at from 9fr. to 30fr. the kilogramme, according to its purity. Horse-hair fabrics are woven of materials of French origin; that which comes from Buenos Ayres is much more expensive, costing from 16fr. to 30fr. Woollen damasks are woven with wool coming from the north of France; the weft is worth from 7fr. to 8fr. the kilogramme, the warp from 9fr. to 10fr. For the mixed silk fabrics, they use warp at a price of 50fr. to 60fr. the kilogramme. The Algerian fabrics are composed of cotton warps and woollen wefts, worth from 5fr. to 6fr. the kilogramme. The price of the cotton fabrics, such as calico and cretonne, used for making prints and chintzes, is from 50c. to 1fr. 50c. per metre; these fabrics are woven in Alsace and Rouen. The cloth used in upholstery is manufactured at Mouy; the widest, used for table covers, is worth in its rough state 3fr. the metre; and that used for covering furniture about 8fr. the metre.

The manufacture of fabrics for upholstery is one of those for which France is most justly celebrated; the tapestry of the Imperial manufactories of Gobelins and Beauvais are without a rival. The production of these fabrics is estimated at about 60,000,000. The exportation of carpets and tapestries is now very large. French woollen manufactures bear comparison with those of the best foreign markets; and their silk fabrics are unrivalled.

GUARDIANS OF THE POOR AND ARCHITECTS AGAIN.

AT the last meeting of the Clerkenwell Guardian Board a letter was read from Messrs. Messenger and Gundrey, architects, enclosing a bill for a sum of £184 4s 4d., due to them for preparing plans and specifications for a supplementary workhouse, proposed to be built some time ago at Highgate, for the reception of the aged and infirm poor. Another letter on the same subject was read from Mr. Trollope, surveyor, enclosing a bill for £70 for work done in connection with the proposed building by order of the architects. Mr. Franklin (a guardian) said that the guardians had no power to pay the accounts in question, and he would move that the clerk be instructed to write to Messrs. Messenger and Gundrey and to Mr. Trollope, to explain to them the position in which the guardians stood in reference to their claims. The Clerk said that the act prohibited the board from dealing with the claim, and he had told Mr. Messenger that he had better apply to the Poor Law Board. Mr. Mence (another guardian) said he thought the accounts ought to be forwarded to the Poor Law Board. He considered that, although the guardians had no power to pay it, the claim of Messrs. Messenger and Gundrey was well founded, for when the plans which those gentlemen had prepared were submitted to the guardians various alterations were suggested in them by the Poor Law Inspector, and they were sent back to the architects to be corrected. A revised plan was sent and forwarded to the Poor Law Board for their approval, and the work was just about to be commenced when a letter came down from the Board stating that they had changed their minds. It would be monstrously unjust, after putting the architects to all this trouble and expense, that they should receive no payment. He would, therefore, move that the account be forwarded to the Poor Law Board. Mr. Thompson (a guardian) here intimated his doubts whether Messrs. Messenger and Gundrey had any claim upon the board beyond the amount of the premium, to which they were entitled for having sent in the best plan. He doubted whether they had been instructed to take any further steps in connection with the building, and whether, if they did so, it was not on their own responsibility. Under these circumstances he thought that the best course to adopt would be to refer the matter to the clerk, with instructions to search the minutes and bring up a report as to what instructions really were given to the architects in reference to the plans and specifications which they sent in for the proposed building. This proposition having been seconded, Mr. Mence withdrew his motion, and the matter stood adjourned for a week.

THE WORKING CLASSES AND TRADES' UNIONS.

THE proceedings at the late International Congress of workmen (says *Galignani*), where such strange theories were propounded, give peculiar interest to an article entitled "Les Associations Ouvrières en Angleterre," by Dr. Montucci, which has just appeared in the September number of the "Revue Britannique." We glean from it the following curious calculation, by which the author endeavours to show what the workman gains by contributing to a trades' union:—Taking the most common case, that of wages between 30s. and 40s. a week, suppose the workman to pay into the savings bank the 4s. a week he now pays to the union. There his money will, at the lowest, produce 3 per cent. interest, payable every six months. As the workman gets nothing in that shape from his union it is but fair to admit that in the case under consideration he leaves his interest to accumulate in the savings bank. Now, calculating the produce of his capital at compound interest, with the regular weekly increase of 4s., the workman, at the end of twenty years, will find himself in possession of a sum of £380. Allowing for illness and other mishaps let it be £300. Now, it is clear that with such a capital at command, a shop may be opened, some profitable business or other may be carried on by the wife, while the husband, not older than fifty, perhaps, at the time, earns his wages as usual at his master's establishment, with the certainty of having secured comfortable means of living for his old age. Comparing this hypothetical state of things with the real one, the author of the article shows that the workman who contributes to the union fund at the end of twenty years has nothing; that by belonging to the association he loses not only the £10 a year to which his subscription amounts, but, also, on an average, three months' work per annum, in consequence of strikes and other direct or indirect interference with the regular course of business; so that his means are reduced to £72 per annum, instead of £110, as they would be in the former case.

CARVED OAK CABINET.

THE subject of our lithographic illustration is a rare old cabinet or chest of cupboards in the South Kensington Museum collection. It is of sixteenth century German workmanship, and is probably composed partly of or generally restored from older materials. The iron mounts and diaper door panels of black oak are evidently earlier than the horizontal and vertical bands of gouge-cut carving. Sixteenth century ironwork, too, was more strappy, wavy, and flowing. The cabinet measures 7ft. 2in. in length, 6ft. 8in. in height, and 1ft. 8in. in depth. It is rudely dovetailed and pinned together, and forms two separate chests of two stages of shelves each, the joint being concealed behind the centre horizontal band of carving. Formerly the sides had massive iron handles to each chest; in one or two instances the rings and roses still remain. The bold design of the lock plates and drop handles demands especial attention. Large latches and handles are still in common use in Germany to ordinary doors and fastenings. Portions of the carving have been painted light red, black, and green, most of which colouring has been scraped or worn away. The ironwork has been restored within the last few years, but with most questionable success. The chamfered stops, both above and below the locking plate, are of deal, and of modern addition.

Our forefathers were given to making cupboards of very large dimensions, of which this one may be considered as a moderate specimen. The general effect is very impressive—a rich medley of forms, yet every detail in proper keeping, totally unlike the wretched shams which crop up from Wardour-street and its neighbourhood. We shall illustrate the details of the cabinet to a convenient scale in an early number. O. W. D.

ANDERNACH.—DETAILS FROM SOUTH DOOR OF CHURCH.

ONE of our lithographic illustrations this week represents some details from the south door of Andernach Church, on the Rhine. The engraving is taken from one of the photographs published by the Architectural Photographic Association. Andernach Church is an excellent example, says Mr. Seddon, in his "Rambles in the Rhine Provinces," of the early Transitional style of the commencement of the thirteenth century, though some portions of its eastern end, particularly of the towers which flank the apse, are pure Romanesque, and no doubt formed part of the older church, which is known to have been built about the year 908.

THE METROPOLITAN DISTRICT RAILWAY.

AT the eighth half-yearly meeting of the Metropolitan District Railway, held recently, it was stated by the chairman that, if no unforeseen circumstances intervened, the line would be opened to Westminster by the 1st of January next. This will join the Metropolitan Extension line from Paddington to Gloucester-road, Brompton, which was opened yesterday, so that by the beginning of the new year, if all goes on well, passengers will be able to go from any of the stations on the old Metropolitan line to Chelsea and Westminster. The works of the section of the line between Westminster, Blackfriars, and Cannon-street (which will be carried under the Thames Embankment and a portion of the new street from Blackfriars Bridge to the Mansion House) are in progress, an equal number of men and horses being employed by night as well as by day, the whole twenty-four hours being devoted to the prosecution of the works. This line, while completing an important link in the "inner circle" of metropolitan railway communication, has in its progress opened up the way for great improvements in some of the densely-populated districts through which the line passes, particularly in the neighbourhood of Tothill-street, Westminster. Vast numbers of dilapidated houses have been demolished, and the passage of the railway through the neighbourhood will give a stimulus to the erection of suitable dwellings for the working classes. The Metropolitan District Railway Company will aid in this work not only by running cheap trains, but by disposing of their surplus lands for the purpose. Forty acres of the company's land, situate at West Kensington, are already set apart for this purpose. It is proposed to utilise a portion of this land for workshops, but the greater part will be appropriated to the erection of workmen's dwellings.

When the line is completed to Cannon-street, the works will be undertaken for its extension to Tower-hill, where it will join the Tower-hill Extension of the line from Moorgate-street, and thus will be completed the "inner circle" of metropolitan railway communication.

IMPROVED DWELLINGS FOR THE WORKING CLASSES IN SHOREDITCH AND BETHNAL GREEN.

THE Improved Industrial Dwellings Company, which has already erected so many lofty piles in the metropolis, is greatly extending its accommodation by the erection of new buildings in Shoreditch The site of these buildings is eastward of Tabernacle-square, on a plot bounded by Willow-walk and Leonard-street, in the direction of Curtain-road. It is between two and three acres in extent. There are six blocks of buildings at present erected, side by side, each seven stories in height from the basement, being one story higher than any of the other buildings erected by the company. The plan may be described as a parallelogram, having a frontage of 56ft. by a depth of 14ft., divided into four sections by a party-wall in the centre and a passage in the middle of each wing. The two centre sections are set back about 3ft. from the front line, for the purpose of giving space for a balcony of that width on each of the upper floors. The balconies are reached by a fireproof staircase, which extends from the basement to the roof. The end sections of the buildings, which are designed for the occupation of separate families in flats, comprise three rooms and a washhouse on each flat. The living-room in each tenement is provided with proper cupboards, and with a fire-range having an oven and boiler. Leading out of the living-room is the washhouse or scullery, which contains in every case what may be called the necessaries of the dwelling—water cisterns, sink, a small fireplace, washing copper, dust shoot, and water-closet. The fireplace in the washhouse may be used for cooking, so that it will greatly conduce to the comfort of the living room in summer time. The front room of the three-roomed tenement is a spacious parlour having two windows The fireplace being situated a little on one side of the centre of the room affords space for an additional bed in the corner when necessary. On the narrow side of the fireplace is a sideboard and cupboard. The centre sections comprise tenements, which are also in flats, and consist of only two rooms and a washhouse. They are supplied with exactly the same conveniences as the larger tenements. The arrangement is the same, and each side of the centre party walls, and every floor or flat, is a repetition of the other. Close to the ceiling of each of the rooms is a ventilator which communicates with air shafts running through the centres of the chimney stacks. The air in these stacks will be constantly rarified by the warmth of the flues, and a system of natural ventilation will be thus produced. It is obvious that by opening the windows a current of external air will pass through every room. The windows are made to open outwards, like ordinary French casements, but the two lower panes are fixed, in order to prevent children falling out. The drainage is effected by means of stoneware pipes, which pass down the corners of the washhouses directly to the common sewer. The dust shaft carries the dust to a covered receptacle at the base of the building. The greater number of the rooms, especially the living rooms, have scarcely any external walls, and will therefore be always warm and dry.

At Bethnal Green, the company has purchased what is known as the Barnet estate, about nine acres in extent, situated near the "Salmon and Ball" tavern. Here, from the lowness of the ground rent as compared with that at Shoreditch, a different class of building may be erected without detriment to the commercial success of the company. The dwellings which the company intends to erect on this site will have the appearance of what are called "breakfast-parlour houses," every occupation having its own front door, and every family occupant a perfect home, completely separate from the residences adjacent. Where required, some of the blocks will be carried four stories high, and will have porticoes to hide the appearance of the doors, which will open into corridors leading to the several flats. There will also be gardens on the ground level behind.

THE POLLUTION OF THE RIVER WEAR.

RECENTLY, Colonel Sir William Denison, K.C.B., R.E., Dr. Frankland, F.R.S., Mr. John Chalmers Morton, the Commissioners for inquiring into the Pollution of Rivers, accompanied by Mr. S. J. Smith, secretary, visited Sunderland to inquire into the pollution of the River Wear. From the evidence given it appeared that large quantities of ballast, rubbish, cinders, and mining refuse were constantly being cast into the Wear. Last year the River Wear Commissioners had dredged 2,000 tons of rubbish, at a cost of £4,500. The foul and poisonous matter from the mines rendered the water of the consistency of pea soup when the river was shallow. Experiments had been made, at a cost of £1,200, to purify the waste water from the mines, but in the opinion of one witness filtering ponds were the only means of attaining this object. With the exception of Waskerley Burn, the Beck of Brancepeth, and the Old Durham Beck, the whole of the streams flowing into the Wear are polluted. The causes are various. In some instances the pumpings from collieries made the water so thick and discoloured that nothing could live in it. In others the cause was the coal washings, for the discharge of which into the river there was no excuse, as the same water could be used over and over again, and need not be turned into the river. At Durham it was the practice to deposit all the building rubbish of the town by the edges of the river, and the ashes from private dwellings were thrown bodily into the water. The sewage of Bishop Auckland found its way into the Wear, from which Durham derived its water supply. Mr. Henderson, a carpet manufacturer, of Durham, said that the paper works poured their waste water into the river, for which there was no excuse, as it could be completely purified before being returned there. At his carpet works they had accepted a mode of dealing with their dye water, which might be followed by thousands of manufacturers. The liquid was run into a cistern in the centre of the dye-house. Thence as much as would pump was conveyed away a distance of 400 yards to a piece of waste ground near the river, where they had constructed a large filtering pond. Here it was filtered and run off in a comparatively pure state into the river, and it was only necessary about once a fortnight to remove the solid matter that had accumulated. The cost of the plan was not more than £200, with the addition of 3s. or 4s. once a fortnight, and he believed that the construction would last for years without alteration or renewal. Another witness said that the conservators of the Wear had jurisdiction only a short way up the river, and while no one was allowed to throw anything into the harbour the inhabitants of Durham and other places did just as they liked, without restriction. When the water was low it became so polluted that fish could not live. Sir W. Denison said that that might be to some extent obviated by having storage reservoirs in the upper portions to trap the floods, and then, by means of sluice gates, the flow of the river could be kept at a mean level. Mr. Alderman Wilson said that he had no doubt but that the corporation of Sunderland would be glad to give their sewage free to any company that would undertake to pump and utilise it. After the examination of one or two more witnesses, the proceedings closed.

An improvement is now being effected in Kensington, involving the demolition of sundry blocks of buildings to facilitate the passage of the traffic through the High-street of the "old Court suburb." On Tuesday, twenty-seven dwelling-houses and premises situated in High-street, Young-street, Market-court, and Gardener's-buildings, forming a portion of the projected alteration, were disposed of by auction, and arrangements made for the immediate clearance of the ground in order to widen the thoroughfare.

CARVED OAK CABINET. GERMAN 16TH CENTY WORK.

Andernach.—Details from South Door of Church.

THE MARBLES OF FRANCE AND ALGIERS.

WHEN touching upon this subject in a previous article, we expressed a hope that ultimately a material so admirably adapted for the purposes of construction would be more extensively used than at present. Many are in the habit of regarding marble solely in the light of an ornamental adjunct to architectural erections, and not equally well adapted to examples where strength and utility are the chief considerations. This erroneous conclusion is based upon the assumption that there are no descriptions of marbles, except those which are suitable for the purpose first mentioned, whereas the real truth is that there are certain descriptions which are endowed with properties rendering them more valuable as a constructive than as an ornamental material. Marbles of the former kind are used extensively in France. They are quarried at Boulogne, Château-Landon, and Jura, and are possessed of a remarkable degree of compactness, a very high crushing resistance, and a closeness of grain particularly adapting them to resist the influence of the weather. They are quarried in large quantities, and are sold at a comparatively low rate. We shall give presently some statistics respecting the price of marbles. In contradistinction to these, there are others which are susceptible of a higher polish, and better suited for details of a purely ornamental character. Consequently they are not quarried with the same regularity and uniformity as the former; the demand for them is fluctuating, and their price is higher. The palace of Versailles owes a large portion of its architectural beauty to the employment in its construction of the celebrated classic marble of Campan. Owing to the cost of this marble (about thirty shillings per cubic foot), its employment is virtually precluded in the present day, when economy in every class of building, from the palace to the cottage, is carefully adhered to.

The transport of the raw material, or what is usually termed the "carriage," is in many instances the principal bar to its employment. Railways have been the means of removing, in a great measure, this obstacle, although the impediment is not, and never will be, altogether destroyed. As an example of their efficacy in the present case, it may be mentioned that previously to their introduction in the department of Ande, the red marble with streaks of a vivid carnation tint cost thirty-four shillings per foot cubed. Now the price has fallen to eight shillings the cubic foot: six times the quantity is used that was formerly required, and its employment is no longer restricted to the building of palaces, cathedrals, and monuments. At the late "Exposition" our readers must have observed a considerable number of splendid marble columns, the majority of which were intended to be used in the new Opera-house. These were quarried at Seumont, Saint-Antonin, situated at the embouchure of the Rhine; Saint Béat, Sarrancolin, in the Hautes-Pyrénées; and at Pourcieux, in the department of Var. It appears, from the report of the Inspector of Customs, that during the last twelve years the exportation of French marbles has been tripled in value and quantity, and that this increase has taken place not merely in the case of ornamental marbles, but also of those which are exported in the block, and in what might be appropriately called a crude state. Similarly to ourselves, continental architects and engineers have the great difficulty of a comparatively high-priced material to contend against when advocating the extended use of marble, but there is no doubt that time and more organised means of communication and transport will gradually remove this serious obstacle.

Passing on to the marbles of Algiers, we find that we are not breaking fresh ground, or are the first to discover their beauty and value. Ages ago they were quarried in great abundance by the Romans, who have left there as well as elsewhere unmistakable traces of that activity and enterprise which contrasted so forcibly with the sloth and apathy of the people they subjected to their sway. It is to be hoped that our Gallic friends may find the opening up of the old quarries and the extraction of the material a source of remuneration and profit. We shall briefly describe a few of the more important of these colonial acquisitions. Upon the banks of the Isser, in the province of Oran, there exists a rare and beautiful marble, to which the name of onyx has been given, owing to its close resemblance in points of transparency and streaking to that particular variety of agate. The depth of the beds varies from 20ft. to 40ft., and the superficial area of the quarry at present determined extends over a space of nearly 300 acres. A considerable exportation of this marble takes place, as well as of those quarried at Pescade, Chenouah, and Nédroma, but the quarries situated at Fondouk and Cape Matifoux are too difficult of access to hold out fair promise of remunerative working until some additional means of intercommunication be opened up. At Telfela, in the province of Constantine, there exists a species of white marble, bearing a great resemblance to that of Carrara. It is also associated with others of a turquoise blue, a variegated azure, a black with white veins, a yellow and a red. The marbles of Bône present a white ground with yellow and blue veins, and those of Génois are greyish-white, streaked with black. It is manifest, from the above enumeration, that the Algerian marbles are not the least sources that that colony possesses of mineral wealth. The quarries of Chenouah and Telfela will probably be worked upon an extensive scale, and sooner than the others, owing to the fact that they enjoy a situation near the sea coast, and are consequently well-adapted for the purposes of exportation. Before these natural advantages, however, can be rendered fully available, not only is capital required, but a proper system of supply according to demand must be organised, and the whole matter conducted upon sound business principles.

The three operations necessary to render marble fit for ornamental purposes are, the quarrying, cutting, and polishing, the cost including two distinct items—viz., that of the raw material and that of workmanship. At the quarries in the Pyrenees, the raw material, in slabs about an inch in thickness, is worth 11d. per square foot; the polishing and cutting costs 3½d., and the carriage to Paris 5½d., making the total cost per square foot, delivered in the capital, fit for actual use, 1s. 8d. Were the demand to increase and become tolerably regular, it is estimated that this valuable building material could be delivered in Paris, cut and polished, at the rate of 11d. per square foot, which would make it as cheap as many descriptions of stone now employed in its stead. Stucco is, in fact, slightly dearer than marble at this price, and imitation jasper and artificial marbles range from 1s. to 1s. 8d. per square foot. Where water power is available, the expense of sawing would be considerably reduced, as the motive power for the machinery would be furnished gratis. In England, as well as in France, all that is required to effect an increase in the employment of the various coloured marbles is a manifestation upon the part of architects and the public generally of a predilection for this class of constructive material. So soon as the demand is established, the supply will follow at a much cheaper rate than has hitherto prevailed. Taking the mean of ten different marbles employed at Paris, the price is 19s. 2d. per cube foot, the lowest being at the rate of 8s. 6d., and the highest at 28s. Some of these are evidently of an inferior description, and not suitable for work of a highly ornamental character, but there is no reason why ultimately the former should not be used in those parts of buildings where durability and strength are the chief objects in view.

PARIS SCHOOLS OF DRAWING AND SCULPTURE.

AT the distribution of prizes to the pupils of the Municipal School of Drawing and Sculpture, which is conducted by M. Justin Lequin, a few days since, M. Robert Fleury, the artist, presided, and addressed the students. Having passed a high eulogium on the talent and zeal of the masters, and urged the students to make all possible use of the resources which were placed at their disposal by the Government, he concluded with a wholesome warning not to abandon industry for the beaux arts, properly so called, without mature reflection. "Industrial art," he added, "offers ample scope for glory; it has the sympathy of all the world—the production of a potter of Athens finds passionate admirers. Anyone may be proud to add his name to the long list of famous art workmen. Believe me, industry offers a fine field for those who know how to distinguish themselves in it. Work, for labour is honourable; it renders men better, and therefore more capable of fulfilling all the duties of life. Develop your faculties by study, and raise industry to the level of art. Remember that the grand epochs which make the glory of nations are also those in which art and industry were at their apogee."

WORKMEN'S DWELLINGS IN LAMBETH.

IT would be well, says the *Daily News*, if some copies of the "Artisans' and Labourers' Dwellings Act" found their way into Lambeth. We are told of a row of cowsheds portioned off as dwellings for labourers and woodcutters; of streets which in winter are swamps to the doorsteps of the houses; of rows of houses without water, and of others where the water has been putrid all the summer; and of the utter absence of all convenience for health or decency. But why are these things permitted to exist? Full power of remedying them is in the hands of the local authorities, and if they are reluctant to move, any four householders living in the neighbourhood may take the matter in hand. They may appeal, first to the local authority, and if in three months the local authority fails to act they may carry their appeal to the Home Secretary. Such scandals are therefore no longer the fault of the law, but the fault of the people of the district. They need not cry to the press, for they can help themselves. Mr. Torrens, by his act, has rendered it possible to remove the worst plague spots of our great cities, and we ought not much longer to hear of human beings living in places not fit for pig-styes. He has put another instrument of physical and sanitary improvement into the hands of philanthropy. Nor need there be any reluctance to use it. The act is very sparing of the owners of such property, charging them only 4 per cent. for money spent in improving it, and granting them a charge of 6 per cent. on money they themselves lay out in works ordered by authority. Of course, as the act is only seven weeks old, it has had no time to work as yet; but we are hopeful that before it is seven years old such a state of things as at present prevails in Lambeth will be among the evils of the past.

Last spring the Council of the Royal Scottish Society of Arts convened a conference in Edinburgh, which was largely attended by provosts, local magistrates, and heads of educational establishments. It was felt that there was a great want of proper information on the conditions upon which aid was rendered by the State for promoting scientific instruction. Application was made for the services of Mr. Buckmaster, who had long been engaged in delivering lectures and attending meetings on this subject in various parts of England and Ireland. Public meetings have been held in a large number of towns in Scotland, which Mr. Buckmaster has attended and delivered very able and satisfactory addresses, which have resulted in the appointment of local committees for the purpose of co-operating with the Science and Art Department in promoting scientific instruction.

ARCHÆOLOGY.

William Rufus's tomb at Winchester has been removed from the position it so long occupied between the north and south doors of the chancel, to a spot between the chantry chapels of Cardinal Beaufort and Bishop Waynflete - close to the sarcophagi which contain the remains of Bishop de Lacy and Sir William de Gaveston, one of the knights banneret of Edward III. In removing the royal tomb a stone coffin was discovered lying near Rufus's tomb, but quite concealed beneath the pavement. Upon being opened, the bones of some person, doubtless illustrious, from the position of the tomb, were found wrapped in sheet lead. The remains are conjectured to be those either of Bishop Eloi, interred in front of the high altar in 1171, or of Bishop Henry Woodlock or de Morewell, buried in 1316. They were not exposed long, and, like those of William Rufus, every care was taken in reburying them.

The *Cologne Gazette* says that some peasants belonging to the village of Mintei (the ancient military colony of Nymphæa), near Kertch, the former Panticapæum, in Southern Russia, recently discovered in a tomb a pair of earrings in gold, the drops representing a stag at full speed and bearing on its back the Diana of Tauris. They also found a ring and some buttons of the same metal, as well as a cameo, cylindrical in form, on which Apollo and Hercules are represented disputing the possession of a tripod. The artists who produced these objects obviously lived in the most flourishing period of Greek art. One of the earrings was sold for 75 roubles, and the other for 105; the latter was immediately afterwards disposed of for 700 to a Kertch merchant, who also bought the other for 500.

A letter from Rome announces the discovery, in a cellar in the Vicolo dei Balestrari, of a marble pedestal bearing an inscription to Hercules, by M. Silius Messala, who was Consul with Sabinus under the Emperor Caracalla, A.D. 214. It is to be observed that this dedication has been excavated near Pompey's theatre, where, under the Biscione Palace, the great bronze Hercules now in the Vatican was found in 1864. The inscription (which is in capital letters) is as follows: "Hercvli Defensori M. Silivs Messala Consvl."

The annual meeting of the Cumberland and Westmoreland Antiquarian and Archæological Society was held at Penrith on Wednesday week. The Rev. J. Simpson read a paper which had been contributed by the Rev. J. Maughan, of Bewcastle, on "Supposed Roman Stations at Kirksteads, Burgh-upon-Sands, and Boustead-hill." The conclusions at which Mr. Maughan arrived were that Kirksteads, near Kirkandrews, was the Glannibanta of the Notitia; Burgh-upon-Sands, Alona; and Boustead Hill, Brementuracum. Dr. Taylor next read a long paper on "Vestiges of Ancient British Occupation near Ullswater, and the Buried Stone Circles by Eamont Side." The ancient British implements found here, said Dr. Taylor, illustrate well the ages of polished stone and of bronze. Referring to the earthworks and entrenchments, he remarked that though we had no vestiges here of what were called "hut circles" or "British dwellings," we have many examples of the lines of ramparts, ditches, and hollow ways or streets which surrounded or permeated those settlements. He concluded by describing the sepulchral relics which had been discovered on Barton Fell and elsewhere. Dacre Castle was then visited and described by Dr. Taylor, who assigned its date to the middle of the thirteenth century. A visit to the ancient church near the castle, and to the Celtic remains on the hill of Dunmallet, brought the day's proceedings to a close.

WATER SUPPLY AND SANITARY MATTERS.

At the last meeting of the Bath Town Council a communication was received from Mr. V. F. Hovenden, secretary of the Baths and Laundries Society, calling attention to the case of the baths and laundries which derive their whole water supply from the River Avon. The sewage of Bath being now so effectually discharged into the river that the water has become utterly unfit for use (at least in dry weather) for the purposes of washing clothes or bathing, unless something was done to provide a proper supply of water the committee will have to consider the expediency of closing the institution during the summer months. This, with other communications, was referred to the cold water committee, which has been appointed to consider the subject of the water supply to the city.

The little town of Kilsyth, Stirlingshire, has set a worthy example to places of far greater importance. The authorities have commenced operations for supplying to the inhabitants thirty gallons per head daily of pure water, brought from springs of traditional celebrity in the hills adjacent.

Notwithstanding the late heavy fall of rain, the quantity of water in store at Rivington, near Liverpool, has decreased during the last fortnight by 213,000,000 gallons. On the 22nd ult. the reservoirs did not contain more than 817,000,000 gallons, whilst at the corresponding period of last year they held 1,584,000,000 gallons, or nearly double the present stock. An opinion has gained currency that the prolonged drought had effected the red sandstone supply; but the Chairman of the Water Committee stated, at the fortnightly meeting of that body on Monday, that he did not believe there was any good ground for arriving at such a conclusion.

At a meeting of the Harrogate Improvement Commissioners, held on Monday evening last, it was resolved to adopt the surveyor's plans for sewerage, at an estimated cost of £7,000, and to advertise for tenders.

Two stained glass windows, executed by Mr. F. Barnett, of Leith, have just been placed in the east side of St. James's Episcopal Church, Leith. They are both memorial windows, one representing scenes in connection with the trial of Abraham's faith, and the other depicting the Resurrection and incidents in connection therewith.

Building Intelligence.

CHURCHES AND CHAPELS.

Crowmarsh Gifford parish church, Oxon, was reopened for public worship on Monday week by the Bishop of Oxford, after restoration. The church, which is said to be upwards of 800 years old, is of the Norman style of architecture. The roof has been taken off, and a new one put on, with an open roof to the nave. New lancet windows, to correspond with the ancient character of the building, have been put in, and the large high pews removed, and the church re-seated with benches in stained deal. The work has cost about £600, and has been carried out by Mr. Moses Winter, of Wallingford, under the direction of J. H. Hakewell, Esq.

On Sunday last the parish church of St. Nicholas, Liverpool, was reopened, after restoration, consequent on a fire which occurred in February last. Occasion has been taken to raise the roof of the nave three feet. A new system of warming and ventilation has been introduced, and the old organ, which was destroyed, replaced by a fine instrument by Willis. Messrs. Culshaw and Summers, of Liverpool, were the architects employed.

Christ Church, Patricroft, was consecrated on Saturday, the 19th ult. It is in the Early English style, and comprises nave, 82ft. by 30ft., with north and south aisles, chancel 30ft. by 20ft., with vestry and organ chamber adjoining. The chancel is laid with encaustic tiles. The principal entrances are at the west end. The nave has an arcade of six arches of moulded bricks of varied colours, with pillars of Mansfield stone, with carved caps of Bath stone, which support the lofty clerestory. The roof has open principals, and is of high pitch. The west elevation is pierced with large circular window, and from the gable springs a lofty belfry terminated with gilt cross. The pulpit is of Caen stone, at the north-west angle of nave. All the seats are open, stained, and varnished. The church is faced externally with Yorkshire masonry, relieved with bands of stone of varied colours. Accommodation is provided for 600 persons, of which 318 are free. The works have been executed by Mr. Southern, of Salford, at an outlay of £3,900, under the direction of Mr. J. Lowe, architect, Manchester.

The additions to St. Oswald's Church, Manchester, comprise a tower and spire, which have just been completed. The tower is divided into four stages, with buttresses at each angle with canopied heads. The tower is faced with Yorkshire parpoints with ashlar dressings. The spire is of dressed ashlar, with gurgoyles at springing of broaches, with ornate lucernes, and relieved with bands of stone of different colours, and is terminated with gilt vanes rising to the height of 150ft. The outlay is £1,300. Messrs Ellis and Hincheliffe, of Manchester, were the contractors, and Mr. J. Lowe, Manchester, the architect.

Upon the northern banks of a little Middlesex rivulet, the Brent, about eight miles from St. Paul's, stands a small church, erected by our early English or Saxon forefathers out of the chalk of the Chiltern Hills. It is one of the rudest edifices of the kind in England. Some attempts to beautify it were made about the fifteenth century, as there are several two-light windows having label mouldings of limestone, besides oaken benches and pulpit and an octagonal font, all of that date. It was somewhat ruthlessly handled in Puritan times, but it suffered most in the eighteenth century, when the oaken benches gave place to unsightly square boxes, and a miserable window of wood was substituted for what was without doubt a fine one in the chancel. The building comprises nave and chancel. It is questionable whether a tower formed part of the original edifice. The Georgians also erected an unsightly inner doorway to the porch. This, with the other unsightly appurtenances named, have lately been swept away. New floors have been laid down, and new benches, altar rail, prayer and litany desks, and stalls (of deal, stained and varnished) have been fitted up in keeping with the style of the church. The chancel floor has been raised, and an organ chamber erected. Mr. C. Jones was the architect; Mr. Nye, of Ealing, being the contractor. The church is one mile and a-half from the Ealing Station, Great Western Railway.

Designs for a cathedral for the city of Melbourne are about to be prepared by Leonard Terry, Esq., diocesan architect, Melbourne, and Robert Speechly, A.R.I.B.A., late resident cathedral architect for Canterbury, New Zealand. Instructions were given in July. The probable cost will be about £80,000, exclusive of tower and spire.

The *Westminster Gazette* states that the lady abbess and the community of St. Marie's Abbey, Stanbrook, have taken the first steps towards the revival of the true type of an abbey and its precincts. The entire scheme has been well matured, and the plans for the building have been carefully worked out before commencing operations. Unlike most modern convents, the whole group of buildings will be quadrangular. Around the four sides of the great cloisters will be arranged the church, chapter-house, refectory, and other buildings of the abbey. The church is to be built immediately. The designs are from the pencil of Mr. E. Welby Pugin.

A new church was consecrated at Exeter on Wednesday, in St. David's parish, dedicated to St. Michael and all Angels. It is built of blue Westleigh stone, with exterior dressings of Hamhill stone, and interior dressings of Bath stone. The stained windows are very fine. Mr. Hawkins, of London, is the architect.

BUILDINGS.

The new Wesleyan college at Headingley, near Leeds, was opened on Friday last. The style is Early Gothic of the twelfth century. The walls of the building are of Potter Newtown stone, with dressings from the Meanwood quarries. A tower rises to the height of 70ft. Messrs. Wilcox and Wilson, of London and Bath, are the architects, and Mr. Whiteley, of Leeds, the contractor.

On Monday, the 28th ult., Messrs. Tarvis's bank at King's Lynn was reopened, after having undergone great extension and improvement; the whole carried out from the designs and under the superintendence of Mr. W. Newham, architect, of the same place.

TO CORRESPONDENTS.

Notice.—Cases for binding the BUILDING NEWS, Vol. XIV., are now ready, price 2s. each.

To Our Readers.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

Received —A. W.—C. B. A.—T. I. S.—W. C. T.—H. H. —W. W.—Rev. E. W.—C. S.—C. L.—C. G. D.—J. W.—A Subscriber.—I. L.—H. L.—H. E. R.—R. P.—J. F.—B. and Son —D. and W.—S. S.—S. F.—R. S., Melbourne, Victoria.—W. H. B.—H. H. S.—A. Shaw.—B. and H.—S. S.—I. R. P.

Correspondence.

BUILDING SOCIETIES.

To the Editor of the Building News.

Sir,—"A Director," in your last issue, in his comparison of the expenses payable in private and building society mortgages, has omitted to state *all* the expenses charged by the latter. I am not sufficiently experienced to say whether uniformity prevails in this matter. The prospectus of a building society of good standing now before me provides that, in addition to the legal and survey fees (which no doubt are very moderate), there is chargeable an *entrance* fee on each of the number of shares representing the amount of the loan, and a "*small* commission" (?) "of 5s. per cent. per annum of the duration of the loan." These being paid by the borrower or deducted from the loan at its commencement would be increased by compound interest during the term of the loan. This, it appears to me, would completely turn the tables and result in favour of private mortgages. I also believe that some societies pay less in professional fees than they charge, and thus unwar-

rantably make profit by the deception. I am an advocate for building societies in principle, but disapprove of many of the constructive details and hope this discussion may result in purging them of some of their evils.—I am, &c,

Fair and Square.

Sir,—In common with many others of your readers, I have been much interested in the correspondence about building societies which has recently appeared in your columns; and although I cannot agree with Mr. Ingress Bell in his conclusions, I thank him for opening the subject, as it will cause intending borrowers to examine the scale of payments adopted by different societies before they become members, and they will then find that building societies form two classes—the one favourable to investors, the other favourable to borrowers.

I have before me an example of each. To the first, I should, if borrowing £300, yearly repay £43 10s. for ten years, making a total payment of £435, of which £135 would be for interest on the £300 borrowed. To the second, I should, for the same amount borrowed, repay £36 per annum, for ten and a half years, or £378 in the whole term, £78 only being charged for interest, which is a difference of nearly 75 per cent. Taking the latter scale, and applying it to the illustration given by Mr. Bell in the Building News, of the 11th inst., the case will stand as follows:—

Original cost of house letting for £36 per annum	£400	0	0
First case.			
Annual payments for ten and a half years on loans of £300 and interest	£36	0	0
Contingent expenses	£10	0	0
Total yearly payments	£46	0	0
Yearly rent of house	£36	0	0
Annual excess of payments over receipts	£10	0	0
Second case.			
£10 per annum invested for ten and a half years with compound interest (say)	£138	0	0
£100 capital invested for ten and a half years with compound interest (say)	£167	0	0
	£305	0	0

So that in the first case I shall have a house of the value of £400, for which I shall have only made cash payments of £205; and in the second case I shall have in hand £305, supposing I have in the meantime been able to invest £10 yearly, with interest and compound interest at 5 per cent.—I am, &c, B. B.

Windsor, September 29.

Sir,—Notwithstanding all the assertions of your correspondent, Mr. Ingress Bell, it has, I think, been clearly shown, by the recent communications in your journal, that a leasehold house yielding the average or at least a satisfactory return of profit, can be obtained through the assistance of a building society by a tenant not possessing the required capital, without sustaining any pecuniary loss by the transaction.

I am, therefore, very unwilling to occupy the valuable space in your columns with any further remarks on the subject, but Mr. Bell's letter of last week contains a statement which I hope will not be permitted to remain uncontradicted. He says, "We appear now to have arrived, by common consent, at the conclusion that in order to borrow profitably at the interest charged by building societies, you must obtain house property at eight years' purchase."

This conclusion has certainly not been arrived at by "common consent," and I cannot agree with him that the property must return over 12 per cent.

I know not from what document Mr. Bell obtained the extract he has given on "the operations of the benefit building societies," but it should not be looked upon as correctly representing the working of such institutions, and it is quite unfair to mystify the question by introducing such matter—more especially the inquiry "Do landlords reap a nett profit in excess of the interest charged by building societies? If not, where is the difference which is to accumulate and replace the principal?"

When the tenant buys a house he becomes entitled to the clear annual income receivable by the landlord from it, and the difference, therefore, between this income and the amount paid to a society will be the principal or outlay during the time occupied in redeeming the mortgage, after which the whole of the landlord's profit will be free to replace the principal and accumulate a surplus fund. In other words, whatever outlay may be incurred during the period of repayment of the purchase money over and above the rent that would have been paid to the landlord will be fully reimbursed by the profit or rent saved after the loan is cleared off, if a moderate amount of discretion has been exercised in making the purchase.

Mr. Bell quotes from a communication of Mr. Bailey Denton, C.E., who states that "the building of houses in towns, if conducted with ordinary prudence, is remunerative; but it is only considered satisfactory when it yields at least 7 per cent. return on the outlay, whereby the principal money may be repaid during the period of duration, with 5 per cent. interest on the outlay after payment of repairs and insurance." But Mr. Denton is referring to freehold houses, and that class of property it is well known can seldom be bought so profitably through the agency of these societies as leaseholds.

It would undoubtedly be most absurd for anyone to contend that all house property can be advantageously obtained by borrowing from a building society. There are numbers of houses returning so low a rate of interest that few persons would think of investing their money in them at all if they could get 4 or 5 per cent elsewhere without risk or trouble.

I freely endorse the remark of one of your correspondents, "that no general rule can be laid down as to whether it is judicious on the part of anyone to purchase through the assistance furnished by a building society or not. Each case must be determined according to its peculiar circumstances." It should in reality be settled by calculation, and upon the result of such calculation three elements have an all-important bearing:—

1. The term for repayment of the purchase money.
2. The difference between the landlord's annual profit and the amount paid to the society.
3. The rate of interest at which this sum is invested, if saved for buying the house without the society's aid.—I am, &c, S. S.

London, September 30.

LABOURERS' COTTAGES.

Sir,—I have read with interest the letters which have appeared lately in your valuable journal on the above subject, and also your abstract of Mr. Bailey Denton's letter to the *Daily News*. There is no doubt that the problem how to build labourers' cottages so as to yield a fair interest on capital when let at a rent that a labourer can pay is one all important to solve, and it appears to me that the closing remarks in your abstract, viz, "to reduce the cost it must be by the use of materials different to those that have hitherto been adopted," point to the real solution. Why is it that cheaper materials are not used? It cannot be for the want of them. I should be inclined to believe that it is simply from an inordinate love of routine, an inexplicable red-tapeism, that forms so large an ingredient in the British constitution. Let us take Mr. Bailey Denton's model figures; let us construct cottages with the same cubic contents, but with the cheapest known material and the most inexpensive labour combined with substantiality, and see for what amount such dwellings can be erected. Suppose we take concrete for the walls, floors, and even the roofs, what material can be used more fitted for the purpose? Totally impervious to damp, a sure preventive of vermin, much stronger than brickwork, and, under the most unfavourable circumstances, not more than half the cost. There are few estates that do not contain the necessary ingredients, clay, gravel, or flints, and presuming either of these can be obtained (say) at 2s. 6d. per yard, what would be the result? Why, that cottages containing 4,400ft. cube, with every moral and sanitary law complied with, would not cost more if built in pairs than £85 each. These are not figures merely; they are facts, and will bear testing. With such a material, as applicable for a mansion as a cottage, for the simplest style of architecture or the most ornamental, why should it be so overlooked? And why should brickwork be so persisted in when a cheaper material is a necessity? It is not only in the walls that the saving is effected; one coat of plaster only is needed, door and window frames can be dispensed with, and there are innumerable other expedients in the detail that can be resorted to which not only lessen the cost but increase the durability of the structure. I am satisfied that, until material becomes a more general study with architects, true economy of construction will continue to be a name only and never become a reality.

There is one more point in Mr. Bailey Denton's letter I would briefly touch on. Is it not a disgrace to our profession that an architect's estimate of cost will rarely, if ever, stand the test of contract? I am ashamed to own that the greater part of the prizes offered for public competition are obtained through this dishonest practice of underestimating. As it is evident that nine-tenths of the committees who award the prizes wink at the discrepancy, cannot the profession take the matter up and use its influence to stamp out such a blot on its character? It would be a salutary law that made an architect pecuniarily liable for the accuracy of his estimates; it would protect our employers from what in some cases is little short of fraud, and in others ignorant blunders, and would raise the standard of our profession above those pettifogging practices into which some of its members are subsiding—I am, &c., W. F. Hooper.

3, Park Prospect, Queen-street, Westminster, September 28.

THE ORGANS AT ST. PAUL'S AND WESTMINSTER.

Sir,—The suggestion of your correspondent, "Western Organ," is an admirable one, but could it be carried out successfully in an architectural point of view? It is true that the vista obtainable by a removal of the screen would be superb, yet, although the sill of the western window is at a great height from the floor, it is very questionable whether even an 8ft. pipe on top of the screen would not hide a portion of the window, to say nothing of the 16ft. pipes. I know, indeed, that the longer pipes might be placed away at the sides of the instrument as at York and Exeter, but if the organ front underwent this flattening process, would not the effect be most miserable and disappointing? Again, if I remember rightly, St. Eustache has no western window, and the whole volume of sound is reflected into the church from the wall, and St. Sulpice and Notre Dame have but comparatively small window openings—the latter a rosace at a great altitude; but with the large expanse of glass at Westminster, I fear that the sound would be in a great degree lost, and the shaking of the glass caused by the reverberation of the deeper notes would be most unpleasant.

If a large organ could be placed at the western end of our cathedrals (or in the transept, as at St. Paul's, Rheims, or Laon), with a small one near the choir, there need not be the smallest difficulty in playing both from the same manuals; a simple composition pedal would bring either or both under control at the will of the performer.

Your correspondent, "Viator," is uncertain as to the meaning of the concluding portion of my former letter referring to St. Paul's, and with your permission, Sir, I will enlighten him. First, however, let me express entire concurrence in what he says with regard to the removal of the organ to its present position in the choir, where, through being enclosed by deep piers (not light pillars as at Westminster), and through its near proximity to the roof, the sound comes crashing down so as to be anything but comfortable. Indeed, at St Paul's, the alarming state of things spoken of by your facetious contemporary *Punch* is often realised. We have "the organist drowning the choir, and a canon in the pulpit." The presence of the dome was exceptional, and even at the expense of a little architectural effect the organ should have been left in its old position, especially as its prominence served in the distance to bring out the vast proportions of the building.

What I *did* refer to in my previous letter was the utter want of order, of system, and even of decency, so palpably apparent in our metropolitan cathedral, the gilding of some of the dome arches and the leaving of others undone, the putting up part of an organ, which has been from year to year a memento of the lack of energy on the part of those who should have been able to raise *any* amount of money. Why, Sir, I can

point out a district church in the east of London, the congregation of which has raised enough, since the works at St. Paul's were begun, to complete organ, screen, and gilding as well, to say nothing of the few coppers necessary for removing the smuts from Nelson's face, or blowing the dust out of the eyes of Cornwallis. One of the latest tombs is of *black* marble, but the difference will not be noticeable in a short time.

Then, too, what is all that ghastly array of black tressels for, barricading every nook right away to the western doors? Surely a simple cord stretched along just before and during service time would be sufficient, without disfiguring one of the noblest conceptions of man as at present.

I write in no unfriendly spirit, but would be one of the first to rejoice at an altered state of things.

It would, perhaps, be looking too far into futurity to imagine the time when the churchyard railings will be removed and the soot washed from the walls, let alone the gilding of the dome externally protected by waterglass or other such solution.—I am, &c, W. C. J.

ST. SWITHIN'S CHURCH, LINCOLN.

Sir,—The following tenders for the new church were received and opened by the committee on Saturday last, the 26th instant:—Patterson, Ruskington, £9,721; Wallis, Rasen, £9,600; Slingsby, Lincoln, £8,600; Lovelee, Branston, £8,559. The committee were surprised to find the lowest tender to be £1,059 beyond the sum proposed to be expended and the estimate accompanying Mr. James Fowler's (the architect) design, and it was through the architect's assurance that his design could be executed for the money, £7,500, that it was selected. In consequence of this discrepancy between the lowest tender and the architect's estimate, the following letter has been sent to the committee signed by three of the competitors.—I am, &c., Fairplay.

(Copy of Letter.)

Gentlemen.—In accordance with the litho raphed instructions issued by you to architects desirous of furnishing designs for a a new church to be built in St. Swithin's parish, we submitted drawings which we believe could have been carried out in their entirety, *including the seats*, for the stipulated sum.

It has been intimated to us that the design selected by the committee cannot be carried into effect except at a considerably increased cost. It also appeared by the instructions that if such a result occurred "it shall be competent for the committee to return such plans to the architect who submitted them, and to select such other plans as may be capable of being carried out for the sums herein specified."

In justice to ourselves and other competitors, we respectfully call upon the committee to carry out this condition, or to permit us to furnish other designs to include the extra sum required to carry the selected design into effect.—We remain, gentlemen, your obedient servants,

Goddard and Son.
Drury and Mortimer.
Bellamy and Hardy.

Lincoln, September 29.

THE CANAL BRIDGE, GLOUCESTER GATE.

Sir,—A resident in the immediate vicinity of the canal bridge for the last twelve years, I can fully corroborate the statement of "A. C. G." respecting it. I can testify to its utter unsightliness, the inconvenience and danger resulting from its narrowness, and the want of security in its rotten rust-eaten railings. Its present state is a disgrace both to the parish and the Government, and demands immediate attention.

To meet the requirements of the case a slice should be taken off the corner of the park, and the bridge enlarged to thrice its present size. It should, too, be sightly as well as convenient, as becomes the principal thoroughfare of so large and wealthy a district. But I earnestly hope, if the Government does move in the matter, the job will not be entrusted to the tyro who is guilty of the lately erected and neighbouring bridges in the park. These deserve a word of description. The podium of stone is out of all proportion to the size of the bridge, and is capped with a clumsy cornice of classical mouldings combined with Gothic foliage. This mongrel cornice, either from its bulk or cost, is not carried along the inside of the wall, the side on which ornament is most wanted, but is seen in section flush with the blank wall. Some squat vases and leggy lamp-posts of cast iron complete the queer *melan c*. The westernmost bridge of the two, instead of having its roadway on a level with the adjacent roads, is sunk between the banks, and the pedestrian has to descend on one side and then ascend on the other. The new bridge now required will, I hope, be placed in competent hands.—I am, &c., M.

A CORRECTION.

Sir,—I should feel obliged by your correcting a mistake which you have made in your criticisms upon No. 34, Eastcheap, City, E.C. The building, &c., was erected for *Messrs. Hill, Evans, and Co., of Worcester, and Martin's-lane, Cannon-street, City, E.C.*, and not for Messrs. Hills and Underwood, as stated in this week's News, and the style is more French than English Gothic, of the nineteenth century.—I am, &c.,

J. Pethybridge,
for R. L. Roumieu,
Architect to 34, Eastcheap.

10, Lancaster-place, Strand, W.C., September 26.

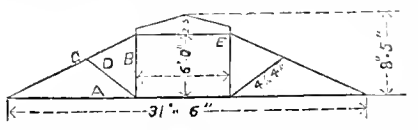
Intercommunication.

QUESTIONS.

[1041.]—ANTS IN HOUSES.—Can you, or any of your readers, inform me, through your columns, the best way of freeing a house from a very small ant with which it is infested?—Edward Monson.

[1042.]—RESILVERING.—I have a German silver watch chain, and the coat of silver has come off, leaving it a yellowish colour: could you, or any of your subscribers, inform me how I could resilver it?—W. L.

[1043.]—TIMBER ROOF.—Will some of your correspondents show me how to work out the strains in a roof of this description, and give me the sizes to make the different parts; also distance apart of principals? A tie-beam; B queen-posts; E straining-piece; G rafter.—Birmingham.



P.S.—What is the tenacity and crushing force per square inch of section for timber used in these kinds of roofs?

[1044.]—MEASUREMENTS OF HEIGHTS.—I am learning to use the aneroid barometer. Could any of your correspondents give me a simple formula for calculating the height by means of the difference of pressure shown by the instrument?—Reader.

[1045.]—PRIME NUMBERS.—Would you allow me to ask, through the columns of your "Intercommunication," what are prime numbers, and what is meant by saying numbers are prime to one another? I cannot find the definition in the books at my command.—Arithmetic.

[1046.]—PAVING AND ROAD MAKING.—I should be much obliged to any of your readers who would tell me what is the proper course to pursue under the following circumstances:—I have lived in my present house for a year and a half, and the road has never been made up properly, or the footpaths paved, although the street is built over continuously with houses. Is it the landlord of the house that is bound to see to this, or the vestry? Now that the winter is approaching the street will be nearly impassable, if not put in a proper state.—Householder.

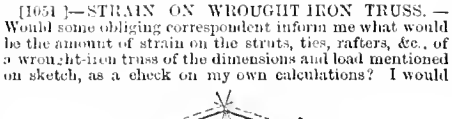
[1047.]—COLOURING BRICKS.—What do the bricklayers wash bricks with before they point them, and give them that peculiar yellow mottled appearance observable in new houses?—S. N.

[1048.]—THE BUILDER'S PRACTICAL DIRECTOR.—I shall be glad if some correspondent will inform me where I can obtain the above work. It was published and issued a year or two ago in parts.—Sandyarms.

[1049.]—GWILT'S ENCYCLOPÆDIA OF ARCHITECTURE.—A student would be glad to hear from anyone having a revised edition of "Gwilt's Encyclopædia" to dispose of.—Address, A. B., 27, Old Jewry.

[1050.]—WATER-CLOSETS.—Would anyone explain the action of the gear for flushing water closets by means of a chain or cord attached to the door, used at some railway stations, and whether likely to get out of order? The name of the makers would greatly oblige. Has anything simpler been invented? The name of the makers of the white ware seats and risers would oblige.—A S Inquirer.

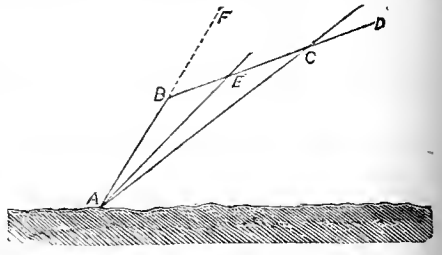
[1051.]—STRAIN ON WROUGHT IRON TRUSS.—Would some obliging correspondent inform me what would be the amount of strain on the struts, ties, rafters, &c., of a wrought-iron truss of the dimensions and load mentioned on sketch, as a check on my own calculations? I would like to have the strains on the struts marked s s, &c.; the ties, t t, &c.; the side and middle portion of main tie-rod; and the greatest crushing weight on each rafter.—Constant Subscriber.



15½ tons distributed over each Truss, including its own weight.
s s, &c., are Struts. t t, &c., are Ties.

REPLIES.

[1008.]—RETAINING WALLS.—I think the following investigation will meet the question of your correspondent "X + Y." Let A B in the cut be the face of the wall; B D that of the surcharged embankment sloping in any direction upwards; A C the natural slope of the ground or angle of repose; and A E a line bisecting the angle B A C. Put angle B A C = θ; angle F B D = θ^1; angle B A E = ϕ; angle B C A = $\phi^1 = (\theta^1 - \theta)$. Let R =



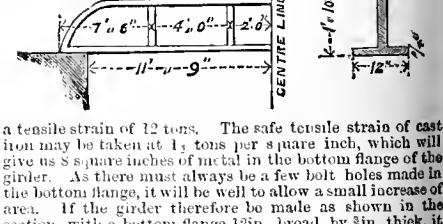
the greatest resistance or pressure against the wall; H its height; and W the weight of a cubic foot of the bank of earth. Then, as a general equation applicable to all cases, we have $R = \frac{W \times H^2}{2} \times \frac{\text{tang.}\,\theta^1 \times \text{tang.}^2\,(\theta - \phi)}{\text{tang.}\,\theta^1 - \text{tang.}\,\theta}$. The value of the quantity tang $(\theta - \phi)$ may be found from the equation tang. $(\theta - \phi) = (\text{tang.}^2\,\phi^1 + \text{tang.}\,\theta \times \text{tang.}\,\phi^1) \frac{1}{2} - \text{tang.}\,\phi^1$. When there is no surcharge the angle and the face of the wall is vertical, the angle A B C = 90 deg., and then $R = \frac{W \times H^2}{2} \times \text{tang.}\,\frac{2\theta}{2}$.—Q. E. F.

[1010.]—WALL FINISH FOR SMOKING ROOM.—The best plan for "A Country Builder" to follow is to give up the idea of papering the room altogether, and to paint the walls a light chocolate brown or maroon colour; they can then, if necessary, be washed, and all traces of smoke removed.—S. C.

[1016.]—SKEW FACING TO ARCHES.—If the arch is built on the square line in brick it is impossible to make the courses range with a skew face. The best plan to adopt is to take the brick arch out again, and start from the proper lines.—M. J., Cardiff.

[1017.]—CONTENTS OF CISTERN.—Multiply length, width, and depth together to ascertain cubical contents; this again multiplied by 6¼ (the number of gallons in a cubic foot) will give contents.—F.

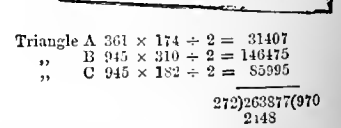
[1019.]—IRON GIRDER.—"Assistant" should put up a cast iron girder, which will be the cheapest kind of thing he can adopt. To find the proportions he may proceed as follows:—Let W = total wall uniformly distributed, which is equal to 23ft. 6in. × 6 cwt. = practically 7 tons. The depth being 1.8ft., the strain at the centre will be given by the equation $S = \frac{W \times L}{8 \times D} = \frac{7 \times 23.5}{8 \times 1.8} = 11.4$, or, in round numbers, 12 tons. We must, therefore, provide sufficient metal in the lower flange of the girder (see figure) to resist



a tensile strain of 12 tons. The safe tensile strain of cast iron may be taken at 1½ tons per square inch, which will give us 8 square inches of metal in the bottom flange of the girder. As there must always be a few bolt holes made in the bottom flange, it will be well to allow a small increase of area. If the girder therefore be made as shown in the section, with a bottom flange 12in. broad by ¾in. thick, it will answer its purpose effectually. The elevation may be as represented in fig. 1. It will make the girder a little stronger at the ends than absolutely necessary, but it is always well to be on the safe side. The top flange may be 4in. by ¾in., and the web or centre part ¾in. in thickness.—C. P. P.

[1021.]—LINING RESERVOIRS.—I would advise "Nemo" not to think of lining his reservoir himself, as he is sure to make a bad job of it, especially when the case is one requiring particular care. He had better get the Pyrimont Asphalte Company to do it, who have special apparatus and appliances for doing that sort of work properly.—Z. Z.

[1022.]—AREA OF A FIELD.—Although not "J. M'Namara's," perhaps "Young Surveyor" will deign to accept the following method of obtaining the total contents:—



Triangle A 361 × 174 ÷ 2 = 31407
" B 945 × 310 ÷ 2 = 146475
" C 945 × 182 ÷ 2 = 85995

...37

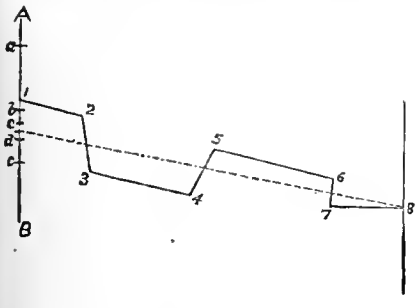
F.

[1022.]—I am exceedingly obliged to "J. M'Namara" for his solution, and for the trouble and patience he has shown me. In answer to the remarks of "Another Young Surveyor," I would observe that the only object of field notes is to plot the survey made, and that I have plotted to scale the dimensions I gave in the BUILDING NEWS of the 18th inst., and found them accurate, since the survey closed. I should not have ventured to trouble "J. M'Namara" a second time unless I was sure that the measurements were correct. I did not plot the lengths in the first instance, and therefore was not aware that they were wrong.—YOUNG SURVEYOR.

[1023.]—BATHS ON THE SEINE.—As far as I can remember, the bottoms of the baths at Paris are fixed to piles driven into the bed of the river. The bottoms are composed of narrow strips of wood, about 2in. wide, fixed about 1in. apart, thus allowing a continual change of water. The bottoms also slope longitudinally, to provide against any difference in the level of the water, which, I believe, is not much affected by the tide at Paris. On the Loire, at Orleans, the baths are floating, and the bottom is there formed by the natural bed of the river. I may be mistaken as to the manner of fixing the baths on the Seine, since the floating plan is certainly preferable to the other, though it may be more expensive to keep in repair.—R. L. B.

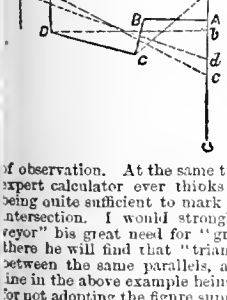
[1023.]—I have frequently bathed in the baths on the Seine, but do not remember having touched the bottom; but there is a similar bath moored in the Lagoon, opposite Venice, of which I noted the construction. It is formed of a number of barges joined together by planks, in the form of a parallelogram. These are anchored, and rise and fall with the tide. Sometimes there is a rapid current through the bath, and to guard against this, and to prevent the bathers being washed under the barges, a grating is fastened to the inner side. The bottom was the natural bed of the Lagoon, said by the man in charge to be 30ft. deep?—A. BEAVER.

[1024.]—TO EQUALISE AN IRREGULAR LINE.—Let "Surveyor" try the following method, which he will find based upon mathematical principles:—Lay the parallel ruler from 1 to 3, move it parallel to 2, and mark the line A B at a. Lay the ruler from a to 4, move it parallel to 3, mark the line at b. Lay the ruler from b to 5, move



it parallel to 4, and mark the line at c. Lay the ruler from c to 6, move it parallel to 5, and mark the line at d. Then lay the ruler from d to 7, move it parallel to 6, and mark the line at e. Lastly lay the ruler from e to 8, move it parallel to 7, and mark the line at f. The dotted line f 8, will be the line required.—T. L. P. HIX

[1024.]—The simplicity of the method shown in figure, which is mathematically correct, of equalising irregular lines is so apparent, that beyond the first operation much explanation is quite unnecessary, all others being similar to the first. In the first place, we must assume any line (in this example G H), and be provided with an accurate pair of parallel rulers. In commencing operations, the parallels must be laid upon the first and third points (in our present example A and C); next, they must be run carefully up or down, as the case may be, until they touch exactly upon the second point (in this case B); while upon this point accurately mark the intersection with the assumed line a; and from the point of intersection draw a line to the third point c; and this line a c will equalise the crooked portion A B C, and allow us to discard the two lines A B and B C. We now take a for the first point, C for the second, and D for the third point, and proceed as before. 'A Surveyor" may find the dotted lines at first slightly confusing; but I have drawn them in so that he may have all the benefit of observation. At the same time, I may remark that no expert calculator ever thinks of dotting in his lines, it being quite sufficient to mark and number the points of intersection. I would strongly impress upon "A Surveyor" his great need for "grinding up" his Euclid, as there he will find that "triangles on the same base, and between the same parallels, are equal." The equalising line in the above example being the line F d. My reason for not adopting the figure supplied by "A Surveyor" was its being too confined for the end in view.—HENRY COCHRANE, C.E.



[1029.]—INCLINE SWARDS.—The slope should not be formed at a greater angle than 45 deg., which, I believe, is the usual angle for railway slopes. I should think 30 deg. would answer the purpose, though a less angle would probably be better if it could be obtained.—R. L. B.

[1029.]—In reply to "Peter Groome," I find terrace slopes formed at two horizontal to one vertical to burn up, in ordinary summers, quite brown, and therefore very objectionable. I would recommend a slope of not less than three horizontal to one vertical; but of course it somewhat depends upon the nature of the soil, position of slope, &c.—T. C. T.

[1032.]—HANDRAILING, STAIRCASING, &c.—The simplest and best work on the above I have yet seen is the "Joiner's Instructor on Staircasing and Handrailing," revised, corrected, and enlarged, by Joseph Galpin, architect; can be had at C. Chalcot's, 9a, Skinner-street, Snow Hill, London; the price is 28s. or 30s. It contains the square and bevel cut, and all information that an amateur would require. I have one, equal to new, I would dispose of for 20s.—F.

[1036.]—IMITATION TORTOISESHELL.—To imitate the marks of the tortoiseshell on horn metallic solutions must be used. To spot it red, use a solution of gold in aqua regia; black, a solution of silver in nitric acid; and brown, a hot solution of mercury in nitric. These solutions must be applied to the right side of the horn. Brown spots can also be produced by a paste made of red lead with a solution of potash applied in patches and subjected some time to the action of heat.—CUMBERLAND.

[1037.]—ETCHING ON IVORY.—Callott's etching ground is a very good one; so is the following, which I use myself:—1oz. of pure white wax, 1oz. of transparent tears of mastic, and 1oz. of asphalte. Reduce the mastic and asphalte separately to powder, and having dissolved the wax stir in and dissolve first the mastic, and then the asphalte. Pour into lukewarm water, and knead it as it cools into balls about 1in. in diameter, which keep closely wrapped. The design can be produced in purple or black by using an acid solution of silver or gold for etching instead of the usual sulphuric acid.—K. F.

BUILDING AND LAND SOCIETIES.

A MEETING of shareholders and others interested in the National Temperance Land and Building Company was held at the City Terminus Hotel, Cannon-street, on Tuesday week, for the purpose of allotting shares which the directors had kept in reserve. Mr. Henry Robinson, chairman of the company, presided, and in his opening remarks invited those present to assist in its further progress by taking up shares. The company had progressed slowly, steadily, and safely. The business it transacted was perfectly sound and profitable. In the first six months of its existence it had lent £300, and at the present time it had advanced £23,000 upon the most undoubted security, and had applications for £7,000 more. The shares already allotted were 3,600, and they had now 4,400 more to allot. The shares, upon which interest of 10 per cent. had been paid, would no doubt have been taken up if the board had not ceased to issue them six months ago. After addresses from other gentlemen the meeting terminated with a vote of thanks to the chairman.

An extraordinary general meeting of shareholders in the Suburban Village and General Dwellings Company (Limited) was held at the Whittington Club on Saturday afternoon last. A new board of directors, four in number, has been formed, with Mr. W. G. Habershon, the well-known architect, as chairman. The secretary, having read the new prospectus of the company, Mr. Habershon said that he hoped better days were dawning for the company. When he had been informed that the interests of a large number of working men were at stake for want of some one to take up their cause he at once came forward. When he heard that £2,000 had been thrown into the sea by the former directors he thought that the best course to pursue was to start the company anew. He went to the Ecclesiastical Commissioners, and offered to stand in the place of Mr. Vigers (a former director) in respect to the negociations for the Milkwood estate, situate between Herne hill and Brixton. After much quibbling and difficulty, he had secured the estate for the company on such eligible terms that if he had taken it on his own account he could have made £10,000 by it. As a professional man, he could assure the shareholders that this was one of the best estates in London, and he could not possibly have hit upon one more suitable for their requirements. Four railway stations were close at hand, and cheap workmen's trains were or would be started. He knew many of the leading employers of labour in London, men such as George Moore, Samuel Morley, &c., and he meant to interest them, and through them their *employés*, in the success of the company. He said that he had no need to go into the old balance sheet, although it was startling to find that of £2,865 10s. subscribed, about £2,500 had been lost. £1,000 had gone in advertisements. For all this money they had not a yard of land to show, and only 334 shareholders. In conclusion, the chairman urged those present to use all their energies in procuring some additional shareholders. Having secured the estate, upon which between 650 and 700 houses could be erected at once when the capital was forthcoming, the success of the company was certain if one or two thousand additional shareholders could be secured. Mr. Pite (Habershon and Pite) having laid before the meeting the plans for laying out the estate (which include a proposal for erecting a building for lecture and reading room, &c.), Mr. Fortescue, one of the new directors, and the secretary addressed the meeting, after which several shareholders put various questions to the chairman, which being answered to their satisfaction, they announced their intention to strenuously support the new directorate. A vote of thanks to the chairman closed the proceedings.

Our Office Table.

On Tuesday, Mr. Alderman Lawrence, the well known builder, was elected Lord Mayor of London for the ensuing year.

Dr. Aldis, medical officer of St. George's, Hanover-square, having written to the First Commissioner of Works with regard to the impure state of the Serpentine, Hyde Park, has received a reply to the effect that the present condition of the Serpentine and the best means of making and keeping it pure and safe are now under consideration, but that it is not intended to undertake any operations of magnitude until Parliament shall have voted the necessary supplies.

The No. 3 contract of the Thames Embankment *i.e.*, that for the short length between the Temple and Blackfriars Bridge), is progressing satisfactorily, the greater number of the piles for the cofferdam having been already driven, and some part of the puddling commenced. It is probable that the entire work will be finished within the time specified in the contract—viz., twelve months from the beginning.

The annual Social Science Congress commenced on Wednesday evening at Birmingham, the Earl of Carnarvon delivering the inaugural address. To-day (Friday) proceedings will be more particularly interesting to the building trade, as one of the papers in the Economy and Trades' Department will be "On a Proposed Bill for the Regulation of Trades' Unions." Papers on kindred topics will also be read by Mr. Mundella, of Nottingham; Mr. Gilliver, President of the Birmingham Trades' Council; Mr. Serjeant Cox, and Colonel Maude, of the Free Labour Registration Society. On Saturday the sewage question will be discussed by the Health Department. On Monday technical education will be the subject in the Education Department, and on the same day the Health Department will take up the question of water supply in large towns; and in the Economy and Trade Department plans for temporarily employing workmen in distress will be discussed. On Tuesday, the Health Department will have brought under its notice the sanitary condition of country villages.

The great clock at the Houses of Parliament, which has been performing with the greatest accuracy since it was first fixed in the clock tower eight years ago, is about to be stopped for a short time, for the purpose of being cleaned by the makers, Messrs. E. Dent and Company, of the Strand, in whose charge it remains.

On Monday morning two houses at Low Town, Holly Hall, Dudley, fell with a loud crash. They were situated at the end of a ruinous row of buildings, in what is called Buggs Gutter, a part of the town thoroughly undermined by the neighbouring pits. Two aged women and two men were seriously injured.

The *Scotsman* understands that the house in Kinnesswood, Kinross, where Michael Bruce, the poet, was born in 1746, and where he died in 1767, and which has been for years roofless and falling into decay, has been purchased by some gentlemen who have resolved to restore it as far as possible to its original condition.

A public meeting was held on Monday evening last at Cleveland-hall, Fitzroy-square, in furtherance of the objects of the Artisans' Club and Trades' Hall Company. It is proposed to build or lease a hall, in the central part of London, capable of holding at least 1,000 persons seated, with library, reading room, and refreshment rooms attached, for the use of trade, benefit, and other societies. The shares are £1 each, payable by instalments of 2s. 6d. per month. Up to the present time 250 shares have been taken up by 140 persons. As soon as 200 shareholders have been enrolled a meeting will be called to elect the directors. The Rev. Henry Solly and Mr. M'Cullagh Torrens, M.P. (who presided) strongly commended the objects of the company to the consideration of the audience.

It is stated that the Ancre Hotel, at Ouchy, Switzerland, where Byron wrote "The Prisoner of Chillon," and Shelley resided, has been so thoroughly restored that not a vestige remains of the rooms which the poets occupied. Even an inscription which the former cut in the stone window sill has been erased, and the house itself is no longer a Swiss château, but a flashy-looking modern hotel. Travellers are thus warned not to trouble themselves to visit the Ancher at Ouchy.

The name of "Faraday" has just been given to one of the streets of Paris. This tribute paid to the memory of a great chemist by a foreign Government cannot but be gratifying to the English mind.

The Prince of Wales has consented to lay the foundation stone of the University of Glasgow, and is expected to visit Glasgow for that purpose on the 8th instant.

Church restorers will probably be extremely interested in the following advertisement extracted from a Staffordshire paper:—"Old Church, Hanley.—To be let or sold, a front pew under the organ gallery. Will seat seven persons, and commands a view of nearly the whole congregation."

"A Lover of the Isle of Wight" draws attention to the sad state of neglect and decay that is so visible in the rooms of Carisbrook Castle. While the building itself bids fair to hold out for a long period against the ravages of time, it is suggested that a trifling outlay would stay the progress of decay in some of the old apartments.

A French chemist, named Dodè, has been engaged for many years in perfeeting a new method of preparing looking-glass, and is said to have succeeded. In place of mercury he uses platinum, but so finely divided that his method is only half as costly as the ordinary one. The platinum is dissolved in nitro-muriatic acid, the excess of the latter being got rid of by evaporation, and the metal left in a state of chloride, and to this is added a certain quantity, not stated, of essential oil of lavender; the platinum immediately abandons the aqueous solution for the essenee, which holds it in suspension. Small quantities of litharge and borate of leao are then added, and this mixture is laid on the glass by means of a brush. Finally, the glass is placed in an annealing furnace, which is heated to redness, the litharge and borate of lead are melted, and the platinum adheres firmly to the surface of the glass. It is stated that for the application of the new method any kind of glass may be used, even bottle-glass, for the platinum causes all faults to disappear, and, which sounds more extraordinary still, that glass thus prepared is transparent, and may therefore be used for windows. It is difficult to imagine a glass at onee transparent and reflecting.

The Freneh papers eomplain that a painting on wood by Albert Durer in the ehureh of St. Gervais, Paris, is in danger of destruetion from negleet, and asks that steps may be taken for its preservation. Such a thing in England would be nothing out of the eommon, but it is unusual with the French, who generally destroy more by restoration than negleet.

The finanee eommittee of a parish not many miles distant, while checking the accounts of their road surveyor, were lately eonsiderably surprised at an item, "For Schoolmaster, £6." Unable to eonceive the neeessity for a schoolmaster in eonnection with bloeks of granite or other road materials, an inquiry was instituted, when it was diseovered that the road surveyor was unable to make out his own accounts, and so had engaged a schoolmaster to assist him, eharging the expense to the parish.

The photographie mission sent by the North German Federation into Upper Egypt, under the direetion of Dr. Dumichen, to take photographs of a series of antique monuments and inscriptions, lately left Cairo on board the "Aigle," which navigates the Nile under the flag of the Confederation. The first halt was made at the ruins of Memphis, near Sakkarah, and at that place, in presence of the French Egyptian antiquarian, Mariette-Bey, and the Federal Consul, Dr. Nerens, the subterranean tombs were suceessfully photographed by aid of the magnesium light. The mission proposed to leave for Thebes shortly after.

The working men of Exeter have established a board of arbitration and conciliation between masters and men. It has been agreed that the board shall ar ibrate on any question relating to wages, working rules, and any other matters that may be referred to it from time to time by employers and employed, and by conciliatory means interpose its influence to prevent and settle any dispute. The board consists of six employers and the same number of *emplnyes*. In ease they eannot agree an umpire is to be called in to settle the dispute.

Patents for Inventions

CONNECTED WITH THE BUILDING TRADE.

36 G. MUDGE. Improvements in Adjustable Lock Furniture. Dated January 4, 1868.

This invention consists of a knob fitted with movable collar and loose pin to work on the ordinary square spindle, a rose fitted with a bush or lining, and a plate with studs, by the combination and arrangement of which the whole is securely and firmly fixed to the door, or otherwise, without screw or thread of any kind whatever.—Patent abandoned.

78 W. E KENWORTHY. Purifying Drains and Sewers. Dated January 8, 1868.

This inventon relates to means of purifying drains and sewers by extracting and burning all the noxious gases therein contained. This result is accomplished by connecting pipes to the drains or sewers, which pipes are placed in communication with the furnaces of steam boilers suitably disposed. In this manner the gases are drawn up through the pipes from the drains and sewers by the furnace draught, whereby to effect their entire combustion in the said furnace, but should any of the gases still remain, they will be at once absorbed or taken up by the carbon or fine dust contained in the flues around such boilers.—Patent abandoned.

88 G. A. HEATH. Improvements in Sash Fastenings. Dated January 9, 1868.

This invention relates to an improved sash fastener, whereby the windows to which it is applied may be more thoroughly secured than hitherto. It consists of a double bolt, the prongs or bolts of which when the window is closed, are caused to project from the pulley stile on either side of the parting bead, and take into suitable recesses made in each sash, so as to prevent their being raised or lowered.—Patent abandoned.

92 J. LEWTAS. Improved Appabatus for Holding and Releasing the Cords of Venetian and other Blinds. Dated January 10, 1868.

For holding and releasing the double cord of a venetian blind of the ordinary width the patentee attaches to the top rail a small frame having a stationary rod or wire for carrying three pulleys, and another rod or wire for carrying two levers or catches The double cord for raising or lowering the blind passes over two of the pulleys, and over the two levers, and over the third pulley is passed a single cord connected to a cranked wire, or its equivalent, for acting on the levers. When the single cord is loose, the double cord can be pulled in either direction, and raise or lower the blind, and when the single cord is pulled the levers are turned so that their ends press the double cord against the top of the frame, thereby effectually holding the cord, and preventing any change of the blind; when the blind has to be raised or lowered, the double cord is pulled to turn back the levers for removing the pressure, and then freedom is given to the said double cord.—Patent completed.

119 C. A. WATKINS. Improvements in the Manufacture of Ties for Painting and other Brushes to be called the Soho Tie. Dated January 13, 1868.

Here the inventor manufactures the ties in the following manner:—On a conical chuck or mould turned to the required dimensions, and slightly greased, he winds string, or other suitable material, until the proper length is obtained; the string is then fastened by loops or knots in the usual way; the two ends are passed under the first turn and left sufficiently long to project beyond the binding of the brush for which it is intended, for the purpose of securing them to the handle, or other convenient part thereof. The string is next coated with glue, varnish, or other adhesive material, allowed to dry, and removed from the mould; it is now ready for use, and may be slipped on the brush at any time it is required The string may be wound on the mould by hand, or by causing the mould to revolve on an ordinary lathe mandrel —Patent abandoned.

142 J. EGGLETON. Improvements in the Manufacture of Bellows Regulators for Water-Closets. Dated January 16, 1868.

This invention consists in making bellows regulators of simple construction, and of materials of such a nature as to prevent their getting out of order, and being affected by damp or liability to decay. These regulators are to be attached to the lever of the valve in the usual way, and are to be constructed entirely of brass and india-rubber. The spindle or rod which runs through the centre, and the plates top and bottom, are of brass, and the intermediate or bellows portion of india rubber; this combination forms an air valve.—Patent abandoned.

148 J. WOOD. Improvements in Windows. Dated January 16, 1868.

This invention relates to an improved construction of windows, whereby the window sashes or frames may be conveniently removed from the cases for cleaning the glass panels, or other purposes. It consists, essentially, of a metal box, bracket, or guide fixed to the window case at about the height of the centre of the top frame, and in the line of the ropes of the lower sash. This bracket or guide is constructed with flanches, between which the rope runs, and these are of such depth that the groove in the lower frame may pass over them; attached to the bracket is a lever projecting far enough to allow the window lines to pass behind it, the lever being actuated by an arm which is pressed upon by the batten rod of the window. When the batten rod is removed, and the lower frame is taken out, the rope which is attached to a hook in the frame is removed, and the lever which is attached to the box bracket prevents the weights from running down. The parting rod, instead of being made in one piece, as at present, is made in three pieces; the upper and lower piece is fixed, but the central piece, which is a little larger than the height of the top sash, is hinged on the inside of the window case, so that it can be pushed into the case, and allow the upper window frame to fold down inside of the window. This is effected by fixing a metal bush a short distance from the wooden sill. In the bush a circular hole is formed, and a slit made on the top side to admit an oval or oblong pivot which is attached to the bottom of the sash. When the sash is lowered, the pivot enters the circular opening in the bush, and acts as a hinge on which the window is folded down to the inside. To prevent the noise occasioned by the sashes when subject to the action of wind or other causes, spiral springs covered with leather or other substance are inserted into the outer side of the sashes; these press against the case so that the sashes are continually forced inwards, and the recoil of the window when acted upon by the wind is prevented.—Patent completed.

152 T. NASH. Improvements in Stoves and Fireplaces. Dated January 16, 1868.

Here the patentee constructs stoves and fireplaces with the smoke consuming and combustion arraegements here inafter described. At the back of the stove or fireplace he has a hot air chamber or receiver which extends downwards in the direction of the ash pit (as illustrated in the drawings). This chamber or receiver is in direct communication with a hollow piece forming a passage of circular or any convenient section; or the stove or grate may be cast or made in such manner that the passage is thereby formed therein, such passage opening into the top of such chamber or receiver, and the chamber or receiver itself opens at its upper part to the chimney. The soot door, instead of being provided with a smaller door, as in ordinary register stoves, has, at or about the same place, an opening which may be fitted with a door valve, and into which opening is fitted the tube or hollow piece forming the passage, as aforesaid, and this tube or passage curves over, or is carried down, dipping into the aforesaid hot air chamber or receiver. The effect of these arrangements will be obvious.—Patent completed.

155 F. POSTILL. Improvements in Kilns or Ovens for Burning or Baking Bricks, Earthenware, &c. Dated January 16, 1868.

The patentee claims the described improved construction of kilns divided by permanent division walls into a number of straight sided firing chambers, constituting separate kilns, surrounding a chimney, with which they communicate by means of separate flues, each chamber or kiln being made to communicate with the one adjoining by means of a flue situated near to the outer walls of the kilns, the introduction of fuel being effected through vertical fuel apertures in the roof of the kiln, substantially as described and illustrated in the drawings.—Patent completed.

Trade News.

TENDERS.

Battersea.—For the erection of a boys' school at Battersea:—

Cooper	£1120 0
Jackson and Shaw	1107 0
Thornton	1090 10
Lathey Brothers	1027 0
Bass	960 0

Finchley.—For the erection of a pair of villas at Fortis Green, Finchley, N., for the Rev. Charles Room. Mr. William Waymouth, architect, 12, Moorgate street, E.C. Quantities supplied:—

Fish	£2590
Axford and Whillier	2515
Webb and Sons	2380
Henshaw	2378
Colls and Son	2376
Foster	2333
Cooke and Company	2272
Merritt and Ashby (accepted)	2139

Havant (Hants).—For assembly-rooms, for Mr. C. Longcroft. Mr. R. W. Drew, architect. Quantities not supplied:—

Deacon	£1720
Stallard	1387
Tear	1343
Carrols	1127

Hemel Hempstead.—For building new infirmary, alterations to tramp wards, and water supply. Mr. G. Alexander Smith, surveyor:—

B. E. Nightingale	£1786
Joseph Harris	1734
J. and W. Savage	1629
Charles Chappel	1603
Alfred Wilkins	1584
Henry George	1480
J. Loveday	1479
W. Sear	1475
W. B. Humphrey (accepted)	1295

London.—For erecting an additional story on Mr. John Cooper's wool warehouse, New street, Bishopsgate. Mr. Herbert Williams, architect, 52, Old Broad street, E.C. Quantities supplied by Mr. Charles Reilly:—

King and Sons	£3851
Conder	3785
Barnsley and Sons	3768
Brass	3647
Ashby and Horner	3650
Browne and Robinson	3550
Piper and Company	3498
Ashby and Sons (accepted)	3456

Middlesborough.—For alterations to No. 6, Sussex street, Middlesborough, for Mr. Thomas Dunn. W. H. Blessley, architect. Quantities not supplied:—

H. Chapman	£865 0 0
W. Oliver	859 5 0
J. Johnson (Acklam-terrace)	852 7 6
C. Thomas	793 5 6
Thomas Wilkinson	785 6 6
J. Ingram and Son	785 0 0
Barron and Robinson	777 0 0
J. Johnson (Marton road)	774 0 0
W. Jameson	772 10 0
J. Rushford (accepted)	772 0 0

Redcar.—For the erection of two houses, Redcar, for Mr. J. Harrison and Mr. J. H. Webster. Mr. W. H. Blessley, architect. Accepted tenders:—

	No. 1.	No. 2.
Picknett and Wynn, Bricklayer, Plasterer, Mason, Carpenter, and Joiner	£705 4 0	£597 12 5

Hedges (accepted)	2240	118

COMPETITIONS.

India.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

Eaton (Norwich.)—For designs for new suburban church. Messrs. Hewitt and Capon, London and Norwich.

ST. MARY CRAY (Kent).—October 8.—For the erection of a new parsonage house. Mr. Christian, architect, 8a, White all-place, London.

BARROW ON SOAR, NEAR LOUGHBOROUGH.—October 5. —For restoration of church Messrs Stevens and Robinson, architects, 45, Friargate, Derby.

MONTGOMERY.—October 15.—For the erection of new wings and other additions to the county gaol. S. W. Poundley, county surveyor, Kerry.

SOUTHEND (Essex) —October 8.—For the erection of a tavern. Mr T. W. Iron, architect, St. Helens terrace, Mile End road.

CAMBERWELL.—October 6.—For the purchase, collection, and removal of dust, &c., in the parish of St. Giles. G. W. Marsden, Vestry Hall.

WEST COWES.—October 19.—For the erection of proposed baths at Cowes. Mr. Woodman, architect, 17, Prince Albert-street, Brighton.

STOURPORT (Worcestershire).—October 19.—For altering and reconstructing a bridge over the River Severn. W. Talbot, clerk, Kidderminster.

COUNTY OF CARMARTHEN.—October 21.—For certain alterations and additions to the county gaol. Clerk of Peace's office, Llandovery.

GREAT NORTHERN RAILWAY.—October 6 —For 100,000 rectangular sleepers, 8ft. 11in. long, 10in. by 5in. H. Oakley, secretary, Terminus, King's Cross

ROMFORD (Essex).—Local Board.—October 10.—For construction of 1,660yds. of oval sewer. Two 8-horse power boilers and centrifugal pumps, &c. A. H. Hunt, clerk.

LICHFIELD.—October 23.—The Bishop's Palace.—Repairing, altering, and enlarging the above-named building, and for adding a chapel to the same. Rev. F. Thatcher, the Palace, Lichfield.

NORTHAMPTON WATER WORKS.—October 18 —For a covered reservoir, 160ft by 150ft. by 17ft. deep. Alexander Milne, architect, 2, Gold-street, Northampton.

PROPERTY SALES.

SEPTEMBER 21.

AT THE MART.—By Messrs. Foster —Freehold estate, with residence, known as Buckhurst Lodge, with farms called Buckhurst Wood and Pennybridge, containing about 194 acres, situate on the high road from Mayfield to Wadhurst, Sussex—sold for £7,360.

SEPTEMBER 22.

By Messrs. Debenham, Tewson, and Farmer.—Leasehold two unfinished residences, Nos. 9 and 10, Florence villas, Feltham, Middlesex, term 90 years from 1862, at £15 per annum—£580.

Leasehold residence, known as Acorn House, Stoke Newington, with stabling and grounds of about 1¼ acres, term 27 years unexpired, at £45 per annum—£500.

Leasehold residence, 15, Somerford grove, Stoke Newington, let at £34 per annum, term 42 years unexpired, at £4 12s. per annum—£285.

Two policies of insurance for £1,000 each, effected with the Eagle Insurance Company on the life of a gentleman aged 58 years—£305.

By Messrs. Broad, Pritchard, and Wiltshire —Leasehold three houses and shops, Nos. 259, 261, and 263, Kingsland road, together with premises in the rear, and seven cottages, and plot of land in Wilmer gardens, annual value £000, term 70 years unexpired at £100 per annum—£3,500.

SEPTEMBER 23.

By Messrs. Bray and Webb.—Leasehold residence, No. 1, Albion terrace, Albion road, Stoke Newington, annual value £55, term 99 years from 1847, £7 10s. per annum—£510.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

William Aylward, Fair-street, Horsleydown, bricklayer, October 7, at 12—Charles Golsby, London Colney, bricklayer, October 12, at 1—William Henry Knapton, Stationroad, Camberwell, gas engineer, October 10, at 12—William James Parker, Rye lane, Peckham, brick agent, October 10, at 12—John Tapper, Lillington-street, Pimlico, and Wandsworth, builder, October 10 at 12 - Joseph Baker, Toddington, Bedfordshire, plumber, October 12, at 11—Wilham Burnham, High Wycombe, Bucks, builder, October 9, at 11—John Dungey, Myddelton street, Clerkenwell, gasfitter, October 9, at 12—Thomas Hughes, Dartmouth Villas, Lewisham, builder, October 10, at 11—John Owen, Bournemouth, builder, October 9, at 1—John Powell, Stracy-road, Forest gate, builder, October 9, at 11—William Richards, Oxford terrace, Upper Holloway, builder, October 12, at 11—Thomas Shakespeare, Latchmere-grove, Battersea, engineer, October 9, at 1—Thomas William Taylor, Colchester and Wivenhoe, carpenter, October 9, at 1—John Henry Tozer, Caledonian-road, King's cross, carpenter, October 10, at 12—George Warriner, Bedford-row, engineer, October 9, at 11.

TO SURRENDER IN THE COUNTRY.

John Finning, Pinhoe, Devon, builder, October 12, at 11—William Henry Jackman, Haylands, near Ryde, builder, October 10, at 11.30—Ambrose Lomax, Gorton, contractor, October 14, at 11—William Lunn, Balderton, Notts, bricklayer, October 14, at 12—Joseph Ryan, Llanelly, mason, September 30, at 11—George Wilson Rylance, Tyldesley, near Manchester, nail manufacturer, October 9, at 11—Thomas Baxendale, Eccleshill, slater, October 9, at 9.30—William Beck, Newbold Verdon, Leicestershire, bricklayer, October 8, at 3—Thomas Gibbs Jenkins, Liverpool, builder, October 9, at 3—John Thomas, Oxton, Cheshire, builder, October 7, at 12.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

December 8, T. Fleming, Greenwich and Southsea, builder—December 8, L. Lee, Kentish Town-road, stonemason—December 8, G. K. Geyelin, Bridge-avenue, Hammersmith, and Argyle square, King's cross, civil engineer—December 10, G. Webb, Old Kent-road, builder—December 10, E. Myers, Camden road, engineer—October 9, T. Dove, Marske, Yorkshire, builder—October 16, A. Fisher, Tunstall, plumber October 15, J. Crossley, Burnley, painter—October 14, J. Labram, Northampton, builder—December 11, G. Lapthorn, High street, Poplar, joiner—October 23, P. Patton, Middlesborough, stonemason—October 23, R. Illingworth, Little Horton, builder—October 14, J. Roseby, Appleby, mining engineer—October 21, S. Downs, Beeley, Derbyshire, stone dealer—October 9, J. Oliver, Everton, builder October 10, R. Thomas, Perran-Ar-Worthal, Cornwall, surveyor—October 15, W. J. Arnold, Tunbridge Wells, builder.

PARTNERSHIPS DISSOLVED.

Todd and Co., Thirsk, joiners—Ogden and Beddows, Little Bolton, builders—Marshall and Taylor, Manchester, engineers—Jones and Co., Newland, Gloucestershire, brick manufacturers—Grimshaw and Co., Openshaw, builders—Hempsted and Co., Grantham, engineers—Illingworth and Yates, Bradford, Yorkshire, builders.

DIVIDENDS.

October 7, J. Warren, South Retford, builder.

DECLARATION OF DIVIDENDS.

W. Stevenson, Wednesbury, builder, div. 1s. 5d.—J. Outram, Burton-upon Trent and elsewhere, timber merchant, div. 1s. 7½d.—C. Howell, Liverpool, slate dealer, div. 1s. 4d.

SCOTCH SEQUESTRATIONS.

William and William Robertson Donald, Paisley, engineers, October 1, at 1.

THE BUILDING NEWS.

LONDON, FRIDAY, OCTOBER 9, 1868.

HOW FAR CAN NATIONALITY BE ATTAINED IN ART?

THIS is a day of ethnology, or, as some writers on art have called it, ethnography; and we believe, at the British Association, much eloquence has been expended in making the term anthropology. Ethnology, in its prehistoric and other stages, is a favourite study of the day, and the curious world is busy in developing itself by pangenesis and other processes from an anthropoid origin. It is not surprising if this turn in the public mind again gives prominency to the question of nationality in art, which, as we lately pointed out, has occupied the pen of a writer in "St. Pauls," who deems it absurd to speak of Gothic as English architecture.

There is to a certain extent a lurking fallacy in the rejection of Gothic, and yet there is a true aim in the rejection of imitations of the past, Corinthian and Ionic, Byzantine and Italian—that perpetual copying of the dead which stands in the way of living art. We ought to be in a condition to obtain an architecture distinctive of the Victorian era. True, but the writer has forgotten one ethnological fact, so far as art and architecture are concerned—that all art is development. If we ever succeed so fully as to determine with regard to the bone and flesh of man that there are distinct races obtained by creation or pangenesis from several pairs, and even if we acknowledge racial peculiarities of idiosyncrasy, we shall still come to a lesson taught by the earliest fragments of art, whether from the bone caves of Auvergne or the lava-hidden houses of Sautorin, that all art, as all knowledge, is but the accumulation of the inheritance of mankind, transmitted from generation to generation, perhaps not according to lineal succession, but with the occasional disinheritance of a series of heirs, still keeping the mental patrimony in the human family.

However far we go back we find savages, it is true; but as yet we trace back civilisation or culture ages and ages before the historic era. We talk of Greek, of Ionic, of Corinthian art, but how far was Greek art Greek, or was Ionic in its essence Ionic? The theorist believes in it on the faith of his school books; but we have traced portions of Greek art back to Egypt and Assyria; and what were Egypt and Assyria—oldest mothers of arts—but themselves the transmitters of older empires, dimly suggested to us by the discoveries of the linguist or philologist or the conformity of weapons and objects of skill? We no longer know what is original, hardly what is characteristic; we complain of the mixture of styles in London, but what did the purist say in Miletus, or Ephesus, or Samos, or the older critic in Babylon? How Greek is the ornamentation of a Greek vase! and yet the Greek vase is not Greek. Under the Greek cities of Cyprus, with their Greek vases, are now found the Phœnician cities, with Phœnician vases and Phœnician inscriptions. In those remarkable objects found at Sautorin, dating from a time before the volcanic cone was divided, there are vases which could never have been Greek, with a Greek ornamentation, as in the vases of after ages, and foliage disclosing an eye for form and a love of beauty when material was rude and skill was mean. The French archæologists fancy these vases were imported, and the produce of a flourishing seat of manufacture and commerce.

Foliage such as has been just referred to is commonly repeated in our buildings to this day. It is an ancient bequest of no specified era; and so it is with regard to much of the elements of art, and new and distinctive inventions are but fresh adaptations. The main body of art may be regarded as common to all countries and all ages, the distinctive features, however striking to us, are in amount subordinate, and yet nothing is so true as the dictum of the writers on this subject, that we can tell the age of buildings by their style, or determine the race of men by their architecture. This within its limits, for we do not stand alone in adopting anomalous architecture; others have done it before us, and there are many influences besides those of race, even where race is known, which determine the characteristics of architecture.

We recognise the eye for beauty in the Ionian and Greek, and we call Ionian art Greek art, and the Ionians Greeks, and, nevertheless, there is no safe reason for believing the Ionians to be Greeks or Aryans rather than Iberians or Caucasian Turanians. We cannot even tell whether it is more likely the love of beauty was communicated by the Ionians to the Hellenes, or by the Hellenes to the Ionians. There are so many influences besides race, as political dominance, but particularly community of religion or language. This may be well studied in the case of Norman architecture, with the adoption of which race had much less to do than is assumed.

Community of religion will influence forms. It must have influenced the temples and burial towers of the fire-worshippers throughout the East, as the cross has influenced Christianity, though we are not sure the cross is an original Christian emblem. Wherever the temples have been sanctuaries for treasure there will be a provision for keeping treasure, and so throughout each detail. One class of worshippers must have the means of lustration, and the Mussulman mosque must have water made to run either from a stream, an aqueduct, or a reservoir. Domestic manners also greatly influence. Where the woman is secluded the form of the house is affected; there are separate apartments, a separate house, or the suppression of the guest rooms of the husband. The greater or less reserve of the women will influence the arrangement of the bedrooms. An English, a Mussulman, or a Hindoo woman cannot live in the same kind of rooms as Ionians and Greeks, who cluster together, and with whom each sitting-room in a house is a bed-room. On the other hand, structure will influence habits. The houses or mud huts of the Egyptians with two rooms are the same as those of their forefathers, and under a different religion this is accompanied with greater freedom of women than among some other Mussulmans.

What is distinctive under such circumstances among the upper classes has little distinction among the poor of all nations. The Irish lived in one room of a mud hovel till lately, on the same condition as poor savages—poorer than the negro, who provides a hut for each woman. The poor labourer in London, Paris, Constantinople, Cairo, and New York must pig with his family in one or two rooms of a large house, as did the needy Roman citizen, who tenanted his apartment in an *insula*.

Thus, there being much common under like circumstances at any epoch, so even, with regard to what is distinctive, much of that is inherited or borrowed. The leading idea is borrowed—of the Hellenic from the Egyptian, of the Ionic from Assyrian or eastern sources, of the Roman from the Etruscan. The modification of Byzantine, which became Anglo-Saxon, Norman, Lombard, and mediæval in its various fashions, is Germanic even in Spain, as distinguished from those modifications which were under Latin influence, passed through Renaissance, and culminated in Italian. It is not, therefore, surprising that, notwithstanding the influence of Italian and its retroversion as Classic in this century, the tendency in this country should have now set so strongly towards Gothic, for it is in this direction the racial influence is to be traced. Classic and Italian in their new shapes are altogether foreign, and Gothic excites greater sympathy. This certainly suggests an explanation, and, if a true one, it also illustrates the tendency of the future.

Taking our share of the inheritance of culture, we must, according to our varying disposition, accept a portion of Classic and Italian as we accept Homer and Dante, but their influence will be affected by the other mental influences of the day. There can be no doubt the Classic taste in England has been greatly modified. It has its hold on the educated classes in well-defined acknowledgment of its claims, but it is its supremacy and its relative position which have suffered. The useful knowledge movement, strangely enough, did not dethrone classics, but confirm them. University College School and King's College School have become as classical as any offspring of the middle ages. Part of this influence, we think, may be traced to the greater value assigned to the English as a nation. We were, a generation ago, quite willing to accept the acknowledged supremacy of the Greeks and the Romans. It may be that the boasting of our American cousins has helped to cure this. In showing the grandeur of the States beyond anything the world had yet seen, even the Phi Beta Kappa rhetoricians were compelled to put Greece and Rome on a lower level. We have been insensibly led to estimate the greatness of the States and of England by a truer standard, and Rome has consequently sunk and Greece been eclipsed. The direct government of India has compelled us to acknowledge that we possess an empire beyond the might of Rome, and the possession of another empire and continent by our kindred in the west eclipses the achievements of Genghis or Timur.

We must not omit as an influence the rising reputations of Watt, Adam Smith, Bentham, Trevithick, Cook, and so many men whose value was not appreciated in their own recent generation, and who are now recognised as benefactors of mankind, putting us on a level with the greatest heroes of antiquity. The progress in our nations of mechanical triumphs has also given us a higher and independent measure of our own capacity. Precisely in the degree that this has taken place has the Classic influence become relatively smaller. Thus, Holland has as great a dominion as in the last century, but England, France, and Prussia have grown larger, and Holland is, therefore, now insignificant. All has favoured the growth of a national sentiment, of a love for old traditions, and thereby of mediæval art, of a love for our own language, of the study of Anglo-Saxon and mediæval English, and of the teaching of English as a great branch of education. If mediæval sympathies have favoured mediæval tendencies in religious matters, we doubt whether they have produced any permanent or rooted effect, and in the period of transition, which has set in, ritualism must take its form and model from the dominant influences.

The causes enumerated have led to the adoption of the mediæval styles as English, but they cannot be regarded as giving them any permanent sanction to be accepted as the art of the country and the age. The tendency is decidedly to seek something English in architecture and art generally, as we have attained it in literature, incorporating what we have inherited from the ancients, and what we can advantageously apply from foreigners, and yet appropriating this according to our own means and our own views.

What we shall do under these circumstances he must be a clever prophet who will find out. The writer in "St. Pauls" and some others seem to think because we have a greater command of glass, porcelain, and iron we must seek our style from such materials, as if we are to abandon marble, stone,

and brick, because we have got further resources. As yet there is no evidence of such abandonment, but on the reverse a tendency to use marble and stone to a greater extent. As to materials we have by no means reached our limit. Gilding is, it may be noted, more freely used in common with other applications of colour, but the resource of electroplating with silver, copper, &c., has been by no means so fully turned to account as it may be. Copper has become a much cheaper metal than it has long been, and the newly adopted metal aluminium is but in the begining of its career, costing, it may be, as much an ounce as in a short time it will for a pound. Nationality will to some extent be dependent on national manners. Ritualism or the disposition for decoration allowed for, there must still be the Protestant element to come into operation. Flats will come into favour, but the manners of the people will yet give a preference to self-contained houses. If we knew that art had come to its term of gestation, we should know what it had to produce, but dependent as the future is on so many influences, political and moral, the results of events remote, unfulfilled, or not yet arrived, it is impossible to give a shape to the progeny of art hereafter. We shall go on essaying, effacing, correcting, and venturing afresh till that supreme day when all shall know an era of art is on us, to be registered in all time.

CITY SAUNTERINGS.

ALTHOUGH, as we stated in our last notice of City buildings, little is at present being done, there is no better field for the observation of the student of architecture than the City presents. Commencing our saunterings at Moorgate-street and proceeding along London Wall, nothing of interest will be seen except Great Winchester-buildings, close to the Broad street Station. These offices are light, though without iron supports, and the carving is particularly well executed. The design is not remarkable. The station next claims attention. It is the most picturesque of all the London stations, as that at Paddington is the most elegant, and that at Cannon-street the most hideous. Proceeding up Broad-street and passing through a large ill-designed structure, known as Palmerston-buildings, finished about three years ago, but not yet half occupied, Bishopsgate-street is reached. A handsome Gothic building, called Crosby House, joins the house just passed through on the right hand. This is a very successful application of Gothic forms to City architecture, and is well worth half an hour's study. A few doors further on is the National Provincial Bank, handsomest of modern City buildings, with its fine groups of statuary and delicate bas-reliefs. Crossing Bishopsgate-street and turning into Gt. St. Helen's, some interesting old brick houses, bearing the date of 1646, will be observed, and also the picturesque porch of carved woodwork of the Church of St. Helen's. The carving of the doorways of the old brick buildings, though of later date, is very good. On entering St. Mary Axe several new warehouses will be seen. Brown's-buildings, No. 9, shows that iron supports need not be ugly. No. 54, immediately opposite, by Messrs. Parr and Strong, scarcely 12ft. in frontage, is a model warehouse, though a pointed instead of a circular headed arch would be an improvement. The flaps, which are of oak, do not appear to be varnished. The ironwork is ample and of good design. The gable is towards the street, a growing fashion by the way, or rather a revival of an ancient one. No. 34 in the same street is an ambitious warehouse, a little over-carved, but with very deep reveals, the entire thickness of the wall, in fact. The lower story is an arcade of three arches, which could scarcely be improved. The water pipes, in the Venetian style, are excellent. To this building, as to many others, it is difficult to assign a style. The ground floor, or basement as it would be architecturally termed, is certainly Venetian in character, but the upper stories are not, and the gable, which is in corbie steps, in the Scottish style, contradicts every other feature in the façade. There are also over the three topmost arches rings of black, red, and yellow brick, spoiling the effect of the whole by introducing variety of colour, which is not distributed over the other portions of the elevation. Almost opposite are three or four curious old houses that we cannot easily reconcile with our ideas of modern London. There is nothing more quaint in Wych-street. In Camomile-street, close by, Mr. H. Fuller is superintending a large warehouse, at present in an unfinished state. The openings in the gable are not arched in the true sense of the word, the heads being nearly in the form of two sides of an equilateral triangle. The lines coincide with those of the gable, but the effect is decidedly bad. Contrast, not coincidence, is the thing which is wanted. By a short cut through Billiter-street, where there are one or two new buildings of no great merit, we reach Seething-lane, passing the church at the corner of Hart-street where Pepys narrates, between his entries of resolutions to give up drink, that he went to hear the children sing. In this lane are two large and comparatively new buildings, the one by Mr. P'Anson, and the other by no one in particular, although more than one architect of repute furnished designs. At the end of Seething-lane is the warehouse in Thames-street, by Messrs. Finch, Hill, and Paraire. It will not add to their reputation, though there is a certain amount of originality about it. The very quaint red brick warehouse in Eastcheap, by Mr. Roumieu, was fully described in a previous number, but it will bear a second view. The metal work is of exceptionally good design, and the doors are the best of similar character in all London. The projection of the hoods to the windows is excessive, and perhaps there is more decoration than is becoming in a building intended for commercial purposes, but the work is thoroughly well done, and the carving is excellent. At the corner of Lombard and Gracechurch-streets is the elaborate building of the City Offices Company—we presume by the Messrs. Francis. The carving is as good as the design is bad. The building is conspicuous, but not striking. Here was a noble site for a cleverly designed work. Being now so near the Mansion House, the new portion of the Union Bank claims attention. It is by Mr. Hardwick. It is set back from the line of the street, and is encumbered by the building at the corner. It is as worthy of its situation as it is creditable to its architect, that is to say, it does scant honour to either. This portion of the City—the neighbourhood of the Bank of England—is not to be lightly passed over. Lothbury teems with handsome edifices—the Imperial Bank, Mr. G. S. Clarke's Venetian building at the corner of Tokenhouse-yard, the Auction Mart in the Yard, and the London and Westminster Bank. The Alliance Bank and other buildings in Bartholomew-lane, which is really a wide street, are amongst the best specimens of architecture to be found in London. In Throgmorton-street, Mr. J. G. Cole has recently finished a handsome building, presenting several peculiarities. The style is palatial rather than Palladian; and if polished red granite can ever be used externally with advantage it is in this instance. The pilasters supporting the first floor, or *piano nobile*, are of this material, as are the quoin stones and architrave to main cornice. The panels beneath the windows of the upper stories are filled in with polished Irish green marble where most architects would have put a wretched *pseudo* balustrade. The reveals of the windows are enriched, and most properly. It is rare to find architects who remember that in most streets, but especially in a narrow one, it is the reveals that are longest in sight of the passer-by. Few pause in front of a building, but we have a side view for an appreciable space of time. In such cases the reveals and returns should be ornamental rather than the front. Mr. Cole has adopted the custom prevalent at Genoa of using considerable decoration in his soffit architecture, those parts, in fact, which in a narrow street catch the eye. The continuation of the carved caps as a support to the architrave is an unpardonable mistake. A large building is in course of erection, immediately opposite, for the Drapers' Company. It has only reached the level of the first floor. It is of considerable frontage. In Cheapside, close to Bucklersbury, Messrs. Tillot and Chamberlain have superintended a building, Nos. 76 and 77, for Messrs. Hobbs, Hart, and Co., the great locksmiths. It is a plain Palladian structure of three stories, having engaged Corinthian and Ionic columns, with an extremely poor cornice. Now the Orders are the Orders, and should be used properly or not at all. This front is a caricature of the Orders and a travestie of Palladio. Anciently Cheapside was called Chepe, but that is no reason for making it in the present day nasty. Buildings like this bring discredit on a noble style at a time when its lovers have much to contend against. In Old Jewry, immediately opposite, Old Jewry Chambers are worth looking at. If not absolutely good they are not positively bad. As the Guildhall is so near, it will be well to take a look at the oak carved work now being placed at the east end. The noble east window, one of the best specimens of modern stained glass which the century has produced, is always worth a visit. It may strike the observer as something unaccountable that so wealthy a Corporation as that of the City of London should allow the hideous west window to remain for a day. He will also marvel that the grotesque figures of Gog and Magog, of no real antiquity or venerable associations, should not long since have been chopped into firewood. Distinguished foreigners, entertained at Civic banquets, must wonder what manner of men can they be who retain such barbaric images. It is is doubtful whether the proprietors of Rosherville Gardens would accept them as a gift. Now let us take Queen-street as far as Thames-street, and pause at Queenhithe, where some enormous warehouses are nearly completed. They are best seen from the river, but they were better unseen. In close proximity, within a few doors of Mr. Burges's spirited warehouse, they show to little advantage, and are certainly examples of what to avoid. The river front is varied, not decorated, by coloured bricks, more or less eccentrically disposed. There is no doubt that a wharf warehouse presents many difficulties, but we never knew a building of any merit which did not. That these difficulties can be successfully overcome, Hubbuck's wharf is a proof. We now come to the British and Foreign Bible Society's house, at the back of Doctor's Commons, passing the still standing tower of St. Mary Somerset, with its many pinnacles. From the river the Bible Society's house is very conspicuous. It is a very large and lofty building of four stories. The style is palatial, with some striking peculiarities. Mr. P'Anson is the architect. There is much in this work that is bold and even original, but there is still more that is weak and common-place. The front is divided into bays by pilasters of slight projection. The capitals of these pilasters support the *bed-mould* of the cornice without the intervention of frieze or architrave. This is as contrary to all rule as it is opposed to all reason. There can be no possible excuse for such an arrangement, especially as the upper story forms a division of itself, having an ornamented string supported by carved caps of minor size. These should have been the true caps, and the upper story should have no pilasters whatever. The cornice is somewhat insufficient, but it might pass. The hip knobs on the roof contribute

much to its effect, but the little balls on the dormers should be removed. The chimneys are successful. The west front is decidedly the most pleasing. The best description that can be given of this building is that it is what is technically called a *coup manqué*. In short, it has missed excellence. Five minutes of sound advice, while the elevations were in pencil, would have rendered the British and Foreign Bible Society's house an ornament to the metropolis; the absence of the advice, or the indisposition to receive it, has dowered the City with another example of what "might have been." Adjoining this building some extension of the offices of the Court of Probate are in progress; they seem to be of no particular pretension. We are now at Blackfriars, where the bridge is making rapid progress. The arch nearest the Middlesex shore is in place; the piers and abutments are worthy of observation. Here we take leave of the reader, hoping that the new street from Blackfriars to the Mansion House, the demolitions for which we have passed in our saunterings more than once, will be worthy of the metropolis, and that the intersections of the principal streets may be adorned with suitable buildings. In laying out a city the corners of the streets are the strong points! Let us, at least, hope that in Cannon-street and the Poultry we may have nothing to deplore in that particular.

SYMBOLISM.—IV.

THE idea in architectural symbolism being that it should be a monitor and instructor, it were too much to expect that in the earliest buildings erected by man, it should, even in its barest rudiments, be called into play. These buildings were for shelter simply, and, as substitutes for the caves, rocks, and overhanging trees, the natural haunts of the troglodytes, were doubtless of the plainest description. Their plan and outline, if at all the fruit of design, were such as were suggested by convenience. Their materials were the readiest to hand. The theory has been commonly held that the Gothic style, in its pillared aisles and groined ceilings, is imitative of the forest avenue with its interlacing branches overhead, amid which heathen and even Christian worship was once celebrated; and the same plea has now and then been suggested for the Classic peristyle. But, not to say that Gothic in all its features is comparatively recent, that the Greek pillar in its plainest form was borrowed from Egypt or Assyria, and that the special imitation here claimed is not properly of the nature of symbolism, we may confidently conclude that the use of pillars instead of massed material as a support for the roof is more consistently explainable in another way.

For the Assyrian and Egyptian architecture, in its great constructional outlines, no symbolism is claimed. The Egyptian pillar, which the Doric in its simplest state almost literally copies, was itself, in all probability, a descendant of the plain wooden post—for the most primitive erections were of wood; and all pillars, Egyptian, Grecian, Roman, and Gothic, have descended from this parentage. The wooden post itself had its prototype in the growing tree, and the first roof its prototype in the spreading branches and foliage which gave protection from sun and rain.

But the groining of a Gothic roof has a history which excludes the idea of nature-copying. The practice of spanning the area of a building with an arch of masonry for roof had its birth at a date anterior to the Gothic arch; and it was found that the semicircular Roman arch, by reason of the great power of its lateral thrust, was inconvenient, expensive, and dangerous. The next step would seem to be the adoption of the transverse semicircular arch, which divided the roof tunnel in the line of its length, economised power and material, distributed and gave various balancing directions to lateral thrust, and presented, in the intersection of the arches, the first specimens of groined work, and, as some will say, the first specimens also of the Pointed arch. It was only needful that the Pointed arch should be substituted for the Roman further to increase strength, economise material, diminish the stress on the wall, and at the same time offer scope for the development of elaborate groining, such as is witnessed in Westminster Abbey. The resemblance to an avenue of trees, at best most imperfect, is simply accidental; the real reason is one of construction. We fear, therefore, that pillaring, arching, and groining possess nothing of a designedly imitative, to say nothing of a symbolical nature.

The plan of the transept Gothic church is of course highly symbolic and meant to be so. The form of the cross, long used in personal and interior architectural decoration, was here with exquisite appropriateness observed in the very foundations, as well as in the whole superstructure of the church, giving a happy variety of outline to the otherwise too uniform roof and lateral walls, and a great addition of constructional strength. It was probably this last consideration of augmented strength, where the transept walls more than supply the place of the most massive buttresses, which led the old architects, as in Salisbury Cathedral, to depart from the simple plan of the cross by introducing two transepts. In this particular instance utility and effect were more studied than literal adherence even to the sacred emblem of the faith.

The imagination has often sought, and not without success, for some symbolic meaning in that chief feature of a complete Gothic church—the spire. Must not an erection so aspiring and so beautiful have been intended to be suggestive of the mounting upwards of the worshipping mind to the skies? The whole service within tends to carry thought and heart heavenward; religion itself came thence, and conducts thither. What more natural, therefore, than that the spire, mounted on tower, gradually tapering and losing itself in mid-air, should have been intended to be symbolic? Beautiful fitnesses, even great discoveries, have been supplied unintentionally. So it has been here. The sharp Gothic roof was no doubt designed to cast off rain and snow in a northern climate. The Gothic spire is simply an exaggerated form of the pointed roof, and its germ is found in the pyramidal roof of the campanile. This at first was comparatively depressed, as still seen in some of the very ancient churches of Germany, but it by degrees became more and more sharpened, until at last, in obedience partly to the idea of beauty and partly to that of utility—for it served to inform at a distance of the locality of the Christian temple—it assumed the dimensions of the finely pointed spire. The fact that very old structures, as at Thun, in France, at Gelnhausen, in Hesse, Worms, and other places in the Rhine country, are of this low pyramidal description, and that the high slender spire proper is certainly of a much later date, should satisfy us as to the historical growth of the structure, whatever the difficulty in tracing the different steps of progress. The loftiest spires carry up with them all the features of the turret roof; the oldest frequently are four-sided, like the roof. They have their gablets and dormer windows like the roof—in some cases, as at Lichfield Cathedral, these lucarned openings are carried up in successive stages, and little windows are sometimes seen piercing the spire into light open work all the way up to the finial—a graceful feature especially prevalent in the churches of Britanny, as, *ex gr.*, in the splendid cathedrals of St. Pol de Leon and Quimper.

On the whole, the symbolical intent ascribed to the Gothic spire must regretfully yield to a more commonplace origin—that, namely, which contemplates the æsthetic and the useful. Piety, however, has the right, now that the structure is a recognised fact, to clothe it with whatever attributes of an ideal kind it pleases, if thereby its own edification is promoted.

As to general plan, structures, whether civil or religious, in the Classic styles, do not seem to have any symbolic meaning in them. They were simply quadrangular or circular areas for certain uses, protected and supported by walls, with projections supported by pillars, in the shape of porticoes and arcades, to afford a cooling retreat from the sun. As already remarked, we cannot say that the pillars themselves were really imitative of nature, although probably copied in the first wooden structures from trees. The real reason why walls, which themselves are the chief supports of buildings, are ornamented with pillars and pilasters, which as such are no support, is that they formed an essential portion of Greek architecture, and that we, in borrowing the whole, have borrowed these its comely parts. They *represent* nothing. In a multitude of cases they support nothing. A plain wall would answer the same purpose. But they are graceful to the eye; they relieve by variety what would otherwise be monotonous surface; they have venerable associations, and belong to a past which we, with all our genius, education, and civilisation, are conscious we cannot, in this particular of stone-massing, outrun or surpass; and so they live, and are worshipped, although elements of a style unsuited to our climate and to the exigencies of our social and public life.

DOING WORK BY PIECEMEAL.

"NEVER do things by halves," is one of our standard national mottoes, and if it be regarded as a dereliction of duty to manage business in this manner, what must be thought of carrying on work by piecemeal? Yet we are, as a people, very prone to execute work in a lazy, dilatory style, instead of bringing the greatest possible amount of energy and activity to bear upon the job in hand. The repainting of Westminster Bridge furnishes us with a case in point. It is about six weeks since operations were first commenced upon the arch nearest the Middlesex shore, and at present the fourth arch is barely completed. At this rate, by the time the whole bridge is painted, it will be necessary to begin again, as the first arch will be in the same state as it was previously to repainting. Even now it has a dingy appearance in comparison with the one most recently painted. It is a lamentable sight for a frequent passenger in the boats to witness day after day half-a-dozen men or so patching away at one solitary arch, instead of six out of the seven being occupied simultaneously by a gang of men, and the whole painting completed in as many days as it will take weeks to accomplish. One might almost imagine that the contractor intended making a perpetual job of it, and had calculated with mathematical precision the exact period it would require for the portion of the structure first repainted to become dirty again, and had thus timed the duration of the process to suit. By these means he would succeed in making the bridge "evergreen."

From the bridge we naturally find our attention directed to the new landing-places, particularly that situated in its immediate vicinity. For weeks this particular example has been allowed to lie idle, although the sheds and ticket boxes have been long since completed. There it floats, rising and falling with the advancing and receding tide, in every sense a veritable "dummy." The wrought-iron bowstring girders, intended for connecting the piers with the shore, still occupy their old uncomfortable-looking position, where they appear to be so balanced as to be ready to drop down at the slightest touch. With respect to these girders it is difficult to imagine why there should be so enormous an amount of material in them.

Instead of being designed for the traffic of foot passengers one would imagine they were intended for railway purposes. The sectional area of the angle-iron diagonal bars is sufficient for a girder of three times the depth. In fact, as these girders are on the bowstring principle, with the loading on the lower flange, and altogether transferred to the upper flange or bow by the vertical double angle-irons, there is little or no strain upon the diagonals.* This is one of the distinguishing features of the bowstring girder compared with the regular Warren or lattice type. There is very little doubt that the footway from Westminster Bridge to the Temple was opened a little too soon. It would have been a preferable plan to have completed the landing piers, their connection with the shore, and the approaches, and finished the paving and lighting before throwing the path open to the public. As it is, it has been one continual scene of unloading flags, riveting up girders, laying down pavement, and putting up hoarding ever since the premature inauguration, to the great annoyance and discomfort of the passers-by. There appears to have been a complete want of system in the management of these various works, and the patchwork principle has demonstrated itself strongly. The little episode of the Metropolitan Board of Works and the railway company waiting for each other, and thus occasioning much delay, reminds one of the notorious "Flushing expedition," which gave rise to the following stanza :—

> The Earl of Chatham, with his sword drawn,
> Stood waiting for Sir Richard Strachn ;
> Sir Richard, longing to be at 'em,
> Stood waiting for the Earl of Chatham.

While upon this subject it might be asked what is intended to be done with the long piece of earthen slope in the neighbourhood of Westminster landing pier. Those who have walked along the path are aware that at a short distance from the bridge the pathway becomes divided, the portion nearest the river wall running downwards to the landing-place, and the other portion rising towards the bridge. Consequently, there is a slope extending from the upper pathway to the lower, the height of which varies from nothing at the junction or division of the pathway to its maximum height, when it reaches the steps leading to the pier. At present this slope consists of earth, and presents a most unsightly and incongruous appearance, its dirty colour contrasting strongly with the light tint of the massive granite walls it is surrounded by. Are trees to be planted on it, or is it to be hidden by a wall of some kind ? Failing everything else, we would suggest that, as the contractor for painting the bridge has his hand in, he might give it a good coat of colour. It will require some time yet to observe how the paving of so large an area of made ground will answer, but there is one point that demands attention, and that is the drainage of the footpath on the south side of the river. The water lies in large pools upon it after every heavy shower, which results from the circumstance that the path is not sloped off similarly to its fellow on the opposite shore, but is nearly on a dead level.

* We find since this article was written that the new Westminster pier was at last opened to the public about two days ago.—Ed. B. N,

NATIONAL ASSOCIATION FOR THE PROMOTION OF SOCIAL SCIENCE.

THE twelfth annual congress of this association opened on Wednesday week, at Birmingham, under the presidency of Lord Carnarvon. The meeting has been of more than average interest, some of the papers read in the various sections being of great value.

POLLUTION OF RIVERS.

In Section III. (Health), on Saturday last, Mr. Rawlinson read a paper on "River Obstructions and Pollutions by Manufactories." He said the growth of trade and commerce and the increase of river pollutions had been simultaneous. Was this necessary ? The area of England and Wales was about 50,380 square miles, or 32,243,200 acres. He divided England into east, north, and west. On the eastern side there were 22 rivers having a combined area of 27,000 square miles: south, 12 rivers, and 5,000 square miles ; west, 22 rivers, and 18,400 square miles. The Aire and Calder, having a combined area of 794 square miles, were the seat of the woollen and worsted trades. The Mersey and Irwell were the seat of the cotton trade. The greatest volume of pollution proceeded from the former, the reason being that wool required washing and cleansing. Rivers were obstructed by mining and iron-making operations, as millions of tons of solids were tipped into the adjoining streams to be removed by floods, to the serious injury of property below. Ashes from steam boilers were thrown into streams and rivers by hundreds of thousands of tons per annum. The pollution of the Yorkshire and Lancashire waters by manufacturers had in some districts proceeded so far as to have limited any extension of the trade, and the increase of pollutions towards the sources of streams had destroyed trade below, as water could not now be obtained for either washing or dyeing. Towns polluted rivers and streams by sewage, which, added to refuse from manufactories, made a compound "thick and slab," scarcely coming within the meaning of the word fluid. The remedy for river obstructions and pollutions must be national. Conservancy boards must be established, one which shall be official and general, others which shall be especial and local. There may be a subdivision of large river areas and a combination of small river areas. Conserving action should have no county, parish, township, or municipal restrictions as to boundaries. The casting into rivers and streams of all solids should be strictly prohibited. All works liable to obstruct streams and rivers should be under the jurisdiction of river conservators. Trade pollutions should be as far as practicable prevented. Refuse was usually useful material in the wrong place. There was no refuse from gas-making which was not commercially valuable. Much that was now termed refuse in manufactories, print works, dye works, chemical works, &c, might probably be found to be valuable. Town sewage was proved to be valuable when used in agriculture. One main restriction might at once be general and imperative—viz., solids must not, as now, be cast into running waters and rivers.

THE DRAINAGE AND SANITARY CONDITION OF BIRMINGHAM.

Mr. Brooke Smith read a paper on "The Disposal of the Sewage of Birmingham." The chief points in Mr. Smith's paper are contained in that read by Mr. Fowler. Mr. Smith describes with some minuteness the sewage works at Saltley.

Mr. W. Fowler, jun., read a paper on "The Sewage of Birmingham." The sewage is discharged by two main sewers into the Tame at Saltley. The total dry weather flow is about 18,000,000 gallons per day, from 10,000,000 to 11,000,000 gallons of which pass along the River Rea main. These sewers were opened about 1853. At that time the Tame was comparatively pure, but when the sewers were opened, it became and has continued a pestilent, foul, and abominable nuisance, injurious to health, and offensive alike to the sense of sight and smell. In consequence of some legal proceedings the corporation constructed large filtering tanks, and made a branch to the canal, to carry away the mud eliminated from the sewage. The process of pumping the soft mud direct from the tanks into the canal boats was, however, found to be practically impossible, because the mud in that condition could not be made available for manure, and the farmers could not deal with it until it had hardened. This mud was now being removed at the rate of about ten boatloads per week, and sold at the price of 20s. per boat to the farmers. Opinions varied as to its value, but Mr. Fowler's father had used it for several years with apparent benefit. The filtering process was ultimately abandoned as a failure, and the tanks are now only used as subsiding tanks. The condition of the Tame had been rendered less odious, but an indescribably horrible stench was emitted from the half-dried mud during removal. The inhabitants have long endured this without seeking redress, thinking that the nuisance was only temporary, but the time has arrived when united and determined action must be taken. Mr. Fowler gave instances of the deterioration of property and of the injury to health caused by these works. The recent experimental irrigation at Saltley, undertaken by the Public Works Committee, was a step in the right direction, though the land was too limited to develope the full capabilities of the soil as a means of purifying the sewage. The primary object in dealing with town sewage should be to purify the streams ; the secondary object to utilise the sewage. At least 1,000 acres of land would be required to deal effectually with the sewage of Birmingham. A sufficient quantity of suitable land might be found in the valley of the Tame. It would be rather costly, and the necessary works would require a large additional outlay; but the undertaking might be made to pay its way, or very nearly so ; and even should it prove otherwise—if the existing system of sewage was to be maintained—no other method of dealing with the sewage was practicable. The whole modern system of sewerage was in his (Mr. Fowler's) judgment a fatal blunder, adopted in a moment of national panic, and had not only entailed upon the country the most useless and wasteful expenditure which had, perhaps, ever been incurred in the pursuit of a fallacious theory, but had at the same time involved the wanton waste and destruction of fertilising elements of untold and incalculable value.

Mr. Thomas L. Plant read a paper on the public health of Birmingham. In ordinary seasons Birmingham was pre-eminent for salubrity over every other large town in the kingdom ; but during periods of high temperature and drought, Birmingham has suffered much greater mortality than other healthy towns. In the summers of 1867-68, the death rate of Birmingham advanced 30 and 50 per cent. beyond the previous quarters ; whereas in the same periods the mortality in London was raised very little, and in Bristol the public health had improved, instead of having declined. Referring to the water question, Mr. Plant suggested that it was no proof that the drinking waters had nothing to do with the bad health last summer, on the mere argument that the public have been drinking the same water at other seasons, or on the ground that the health of the borough has since improved, for the quantity of water drank in hot weather is considerably larger than under circumstances of moderate temperature. A sample of water of the Birmingham Waterworks Company, drawn direct from the main, was found by Mr. Alfred Bird to contain 5½ grains of organic matter in the gallon. Another specimen of water, drawn from a pump in Northwood-street, was found to contain less than one-eighth part of a grain of organic matter in the gallon. Here were two specimens of the waters in Birmingham, the company's containing forty-four times more organic impurity than the other.

In the discussion which followed,

Mr. Holland (Government Inspector) said he did not believe that the whole difficulty had arisen from the water-closet system. If they had no water-closets at all they would have two-thirds of nasty and useless fluid to dispose of instead of three-thirds of more nasty but useful fluid. Birmingham was in a most favourable position for disposing of its sewage if the authorities would boldly face the difficulty, and go far enough out. One of the causes of the impurity was the middens and privies with which Birmingham was covered.

Mr. Alfred Bird said that after analysing the company's specimen he drew a sample of the company's water in his own establishment, and on comparing it with that brought by Mr. Plant, he found that it was totally different. The company's water was purity itself compared with that brought by Mr. Plant. He wrote to Mr. Plant pointing out the difference in the waters, and suggested that Mr. Plant should collect six specimens of the company's water from different parts of the town, which he would analyse. Mr. Plant, however, was satisfied with the previous analysis. As an analytical chemist Mr. Bird urged that he would not publicly adopt the report of an analysis of any water unless he had collected the samples himself. Knowing that the water varied in different parts of the town Mr. Plant ought to have accepted his offer.

Mr. Rawlinson said it was quite possible to draw different samples of water from waterworks mains in any town, and yet it should be one and the same water, but under different conditions. If an engineer were not careful to arrange his mains so that there should be a constant level current through all the mains—if there were what were

called "dead ends," the purest water would be found to be foul and stinking. The samples spoken of might have been fairly drawn, but had not been drawn under proper conditions.

Dr. Farr said that Mr. Bird was not responsible for an analysis of the water supplied by the company, but it was Mr. Plant who was responsible for the collection. It was Mr. Plant who brought the charge, if any, against the company.

Dr. Alfred Hill, the borough analyst, said he was in the habit of analysing the company's water. Taking the average of thirty-one months, the total solid matter in an imperial gallon of water was a little over 30 grains, and the average of volatile combustible matter—commonly called organic matter—was 2·6. At different periods the water varied very much.

Mr. Clayton described a visit to the courts off Snow-hill, Slaney-street, Weaman-street, Potter-street, London 'Prentice-street, and other streets in that neighbourhood, and said that anything more disgraceful could not be imagined. The places visited were taken indiscriminately. The stench in some places was unbearable. There were reeking cesspits, the ashes flowing over into the courts, and privies without any seats to them. Let the Mayor inspect these places, and then say that an officer of health was not needed in Birmingham. They went into Balloon-street, where the ashpits not only overflowed, but extended halfway across the court before they were emptied. This was not merely a specimen of to-day, for twenty-five years ago the same state of things existed. A greater curse had never been brought into a town than the present system of sewerage in Birmingham. They had a long line of sewerage without a single ventilating shaft from beginning to end. Mr. Clayton strongly condemned the untrapped drains communicating with the main sewer, thus bringing pestilence into every house.

Dr. M'Adam (Edinburgh) said an inspection of some of the lowest localities in Birmingham did not impress him that Birmingham was worse in respect of cleansing and drainage than Edinburgh or Glasgow.

The Mayor of Birmingham said that the municipal authorities in various large towns, and particularly in Birmingham, had so far grappled with the subject that the duration of life in this country was increasing. In Birmingham £200,000 had been expended on their sanitary system within twenty-five years. It was now contemplated to dispose of the sewage, and 140 acres of land had been taken for that purpose. So far the result had been highly successful. At present it was only an experimental trial, but, if found as satisfactory as anticipated, the system would be largely extended. In disposing of the sewage, it must be remembered that there was a River Commission, and that the occupiers of land surrounding the town watched with vigilant care lest their health and comfort should be interfered with. At the present time there was an injunction in force to prevent the council from taking the sewage into the river. As to the shaft system for the sewers, what were they to do, except to take the gases into the open air, endangering the lives of the inhabitants?

Dr. Foster, on the question of scavengering, said that in London and Bristol scavengering was carried out in a most complete manner, and these were the two healthiest towns in England.

Mr. Rawlinson, in reply, first addressed himself to the question of trapping private drains, and applying ventilating shafts to the public sewers, strongly contending that it was foolish prejudice which prevented men having the public sewers ventilated into the streets, and yet allowed gases to accumulate and to permeate their own dwellings, causing incalculable mischief, disease, and death. Let them look at London, where the sewers were ventilated into the streets by thousands of shafts, and yet its death-rate was lower than any other town. Just in proportion as the sewerage system had been extended and the ventilation had been neglected, so had the death-rate in certain towns increased. It was the stupidity of people, who would not be taught what they were to do. They would not ventilate and let out the gas. His conclusions were practical and general. They were that excess of disease in the human being was not in the climate, the locality, the atmosphere, the water, or the change of seasons—these were the excuses; but it was within the four walls of their dwelling. He strongly urged the appointment of medical health officers, and that they should make themselves thoroughly acquainted with sanitary science.

Mr. Plant, in reply, said he did not comply with Mr. Bird's request to select six specimens of water, because if they had contained less organic matter, it would not have been a less fair test for the community than by taking a single specimen; and if they had contained more it would have been unfair to the company.

The President (Dr. Farr) closed the discussion. He said it appeared to him that the water supply of Birmingham was not satisfactory, and it might be well worth the consideration of the authorities of Birmingham to ascertain how they could get Birmingham supplied with water of the best quality. With regard to the drainage, they naturally looked to the large towns for something like a true solution of this difficulty. The only remedy appeared to him to get all these offensive matters upon the land, where they would be sources of fertility and wealth to the country.

In Section IV (Economy and Trade.) on Monday last, the question for discussion was, "In what manner can arbitration and conciliation be best applied in the settlement of disputes between employers and employed?" Mr. Mundella, of Nottingham, read an elaborate paper on

ARBITRATION IN TRADE DISPUTES.

Mr. Mundella, having briefly reviewed the rise, progress, and action of trades' unions, asked, Is it not desirable that some better means should be devised to arrive at the market value of wages than such barbarous expedients as strikes? "Strikes are to the social world what wars are to the political world. They become crimes unless they are prompted by absolute necessity." These are the words of Mr. Geo. Odger, one of the most intelligent trades' unionists of this country. The idea of Courts of Arbitration and of Conciliation, as a means of settling trade disputes, is by no means a new one. Such courts were established by law in France in 1806, and have been, with some modifications, continued to the present time, under the name of *Conseils des prud'hommes*. Their functions extend to every question that can arise in manufactures and trade, *except that of fixing a rate of wages*, which, however, when agreed upon between employer and employed, they can enforce. It must be borne in mind that these councils, having no power to fix a rate of wages, can only be appealed to for the termination of disputes; they can exercise no influence to prevent their arising. Also, that the right of combination has only been conceded in France so recently as May, 1864. During 1867, a bill was introduced by Lord St. Leonards for the establishment of "Equitable Councils of Conciliation." That bill now forms a part of the statutes of the realm; but Mr. Mundella does not anticipate from it those happy results for which its author hopes. So far as the scope of the act admits it may be useful, but only in the same degree as the "Conseils des Prud'hommes," for it is specially provided that nothing in the act "shall authorise the said council to establish a rate of wages or price of workmanship at which the workmen shall in future be paid." Its action can only be retrospective, and as no remedy can be effectual which does not provide for a future rate of wages, and as such future rate must entirely depend upon the mutual agreement of masters and workmen, and as such agreement can only result from a good understanding between the parties, it is not to legislation but to the good sense and good feeling of both that we must look for the effectual remedy. He had no faith in any arbitration by persons uniformed and uninterested in the particular trade they arbitrate for. Arbitration, to be effective in preventing disputes, must be the result of a system of open friendly bargaining in which masters and men may meet together and talk over their common affairs, openly and freely. Mr. Mundella then traced the circumstances which led to the formation of the Nottingham Board of Arbitration, and illustrated its operation, and the specific advantages derived from it. For 150 years before the formation of the local board the history of the Nottingham wrought-hosiery and lace manufactures is a history of contention, lawlessness, and crime. From 1710 to 1820 frame-breaking, rioting, and outrages against person and property were of constant recurrence. This deplorable state of things arose from disputes about wages and opposition to improved machinery. The progress of these improvements was for many years delayed by that opposition, and twenty to thirty years of the greatest depression and suffering accrued therefrom to the hand-frame knitters; and the amendment of their condition and their subsequent elevation were only effected by those very improvements in machinery which they had blindly and persistently done all in their power to retard. From 1820 to 1860 offences against persons and property diminished, but combinations were better organised and strikes increased. The workmen generally regarded their employers as their natural enemies, and the cupidity and oppression of some gave countenance to this idea. After a strike of ten or eleven weeks in one branch, in the autumn of 1860, the Board of Arbitration and Conciliation was originated. This was the third strike in the same branch that year. The branches of the trade not on strike supported this one in its resistance. After many weeks the manufacturers assembled to consider what steps should be taken to bring the strike to an end. There seemed to be a general feeling that there were but two courses open—either to submit to the demands of the workmen, or to stop all other branches, and to lock up the factories in order to deprive the men on strike of the support which had been afforded them. Happily there were some present at that meeting who, wearied with the constant strife and shocked at the social mischiefs accruing therefrom, suggested that conciliatory means should be tried. After much discussion the workmen were invited to meet the masters, and endeavour to come to some arrangement. This invitation was accepted, long discussions followed, and the strike was settled by mutual concession. But they did more than this. Determined to make an effort to prevent difficulties in the future, the Conference passed the following resolution:—"It is further agreed that, in order to prevent a recurrence of strikes, which have been so disastrous to employers and employed, and to protect the mutual interests of both master and workmen, a board of arbitration be at once formed, to consist of six manufacturers and six operatives, to which all questions relating to the wages of labour shall be referred. The decision of the said Board to be final and binding on all parties." This was signed by both parties. The workmen immediately elected their representatives by the universal suffrage of the members of their unions. The manufacturers called a general meeting of their own body and elected theirs. The number finally agreed upon was nine from each class, and on the 3rd December, 1860, these eighteen persons met together to carry out the proposed scheme. The first deliberations took place under great difficulties. There were no rules or precedents to guide them. Many of the manufacturers and workmen regarded the scheme with ridicule and distrust. As, however, about two-thirds of the employers were induced to give it a trial, and as the more intelligent of the workmen were of the same mind, they persevered. He did not say that the rules by which they had been governed were models of unerring sagacity; but he did say, for the encouragement of all those who desire to achieve the like happy results, that, judging from past experience, wherever men meet together with the honest desire to arrive at the truth and to do justice to each other, a good understanding is almost sure to follow. At the first meeting a president and vice president were elected, and a committee appointed to draw up rules. With mutual courtesy, the working men proposed a manufacturer as president and the masters a workman as vice-president, and this precedent has ever since been followed. The rules were produced at a subsequent meeting, and they have remained unaltered to this time. They are exceedingly simple and brief. In their progress they encountered difficulties, and made mistakes; but having steadily kept one object in view—that object the adjustment of all questions relating to wages in a friendly and amicable spirit—they had succeeded in conquering them all. They have had instances where employers have acted contrary to the decisions of the board, and two where workmen have refused to accept those decisions; but the steady adherence of the majority of both parties to their decrees had always, sooner or later, brought the recalcitrants back. And the Nottingham Board now governs the hosiery trade of Nottinghamshire, Derbyshire, and the north of Leicestershire, including Loughborough, and the number of persons employed in these districts cannot be less than 60,000. The number employed in the hosiery and lace trades, which are now under the same system, exceeds 100,000 persons. The articles manufactured in

the hosiery trade are exceedingly numerous and varied in character. All work is paid for by the piece. Since the foundation of the Board, all variations in prices, up or down, have been referred to it. The simple fact is, that the employers, who represent the buyers of labour, and the workmen, who represent the sellers of labour, sit down together and mutually bargain what price shall be paid for the commodity. It is very rare that the price originally proposed by either party is the price ultimately agreed to. Alterations or concessions are generally made on both sides, and the price once fixed is considered mutually binding. In order that no hasty decisions may be made against either party, a month's notice must be given before any change of prices can be discussed. Owing to the variable character of the trade, small differences and disputes are constantly arising. All such questions are, in the first instance, referred to a committee of inquiry, and are generally there settled. Should the committee not be able to agree, however, they are finally adjusted by the Board itself. When a question had been fully discussed, and they had not been unanimous, they had always said, "Don't let us vote; let us try to agree," and by mutual concession they had never left a meeting without having first agreed. Mr. Mundella's experience as president of this board for nearly eight years convinced him that nothing is more conducive to the success of a trade and the growth of kindly feelings amongst all parties engaged in it, than the existence of such a representative and legislative body as the one described. If the workmen of any branch conceive that they have grievances to complain of, a delegation may attend the board, in addition to the ordinary representatives of that branch, and lay the case before it. The Board had never met without settling at least half-a-dozen questions, which, if allowed to remain open, would produce irritation, and sometimes lead to strikes. The levy to the trades' union, which averaged 1s. to 1s. 6d. per week, and every farthing of which went in fighting the masters, is now only 1s. a year in several of the unions, for the needful expenses of the Board of Arbitration, the payment of the trade secretary and the delegates. The balance is saved to the workman, and is equivalent to a considerable advance of wages, without costing the master or the consumer one farthing. But, whatever may have been the material gain to all classes, the moral gain has been beyond all computation. The lace trade, which, if possible, has had a more embittered past than the hosiery trade, was the first to follow the example. They adopted the same rules, but appointed a retired manufacturer as umpire, in case of an equal vote, and they have worked through a busy time with marvellous success, and without once requiring the services of the referee. Boards are established at Leicester, two at Bradford, in the south of Scotland, in Derby, and several other places, and during the past month have been organised for the entire pottery district, for various trades in Manchester, and for the building trades of Exeter and Nottingham. In the last case only two employers out of more than 150 had withheld their signature. But what is of more importance, the great mining associations of South Lancashire, South Yorkshire, and the whole of Scotland, have given in their adhesion to this principle, and are prepared to meet their employers and arrange for bringing it into practical operation. Lord Elcho, the Earl of Lichfield, and other members of the Royal Commission invited him (Mr. Mundella), two months ago, to meet a number of the largest employers and leading trade unionists, with a view to forming an association to extend voluntary courts of arbitration throughout the kingdom. There is great work to be done, and work which will amply repay the labour and self-sacrifice it demands. Mr. Rupert Kettle has for three or four years worked in the same direction with great success. He has established courts at Wolverhampton, Leeds, and various other places, on a similar principle to those Mr. Mundella had described, except that he avails himself of the provisions of the 13th section of the 5th of George IV., cap. 96, which gives powers to enforce the decisions of Courts of Arbitration. Mr. Mundella did not pretend to say that the Nottingham plan is better than Mr. Kettle's; but having worked for eight years without having felt the need for the compulsory clause his sympathies are in favour of the voluntary system, more especially as Mr. Kettle has not found it necessary to have recourse in a single instance to compulsion; and if it were resorted to it would tend to destroy that harmonious feeling which the working of the plan has induced. Strikes have frequently arisen from mere misunderstandings, where hardly any money value is involved on either side. Sometimes it is the uncouth and dictatorial manner in which a reasonable demand has been made, and at others, the arbitrary refusal to listen to a courteous request, which has involved the parties in contention, and once in the heat of conflict the matter in dispute is forgotten in the strife for mastery. All this, however, is avoided where a properly constituted body meets at stated intervals to exchange ideas in friendly and courteous intercourse. Mr. Mundella did not advocate arbitration to the exclusion of other remedial measures, such as co-operation and industrial partnerships. But before these can be adopted a good understanding must have been brought about between masters and men, and arbitration may be introduced where they are difficult or impracticable.

On Wednesday, the concluding day of the meeting, several papers were read on the question of "Arbitration and Conciliation in the Settlement of Disputes between Employers and Employed." In addition to the papers read, the section was favoured by a statement, by Mr. Rupert Kettle, of Wolverhampton, as to the operation of the plan adopted in his district, which holds in reserve the power of appeal to law as a final means of enforcing the decision of a court of arbitration. The debate was continued with great vigour and ability. Special arrangements having been made to admit working men into the meeting, the section had the advantage of receiving information from varied classes. The section was very clearly in favour of the plans proposed by Mr. Mundella, and were averse to the introduction of legal measures for the enforcement of the decisions of the courts.

CEMETERY CHAPELS, BIGGLESWADE.

THE designs for these chapels are by Messrs. J. Ladds and J. M. Hooker, and were selected in open competition from about twenty other sets sent in. The chapels, lodge, fence, walls, and railing are being carried out by Mr. Howe and Mr. Twelvetrees, of Biggleswade. The contract price is £815. The materials used are white bricks, with Bath stone heads and sills to windows, and stone copings, with a few red brick bands and arches. The spire is 85ft. to top of vane, and each chapel will seat thirty-five persons.

THE ARCHITECTURAL ALLIANCE.

WE have received from the secretary a report of the meeting of the Alliance, held on the 2nd of July last, at 8, Montague-street, Russell-square, Mr. T. Roger Smith in the chair. In 1867, as our readers are aware, the meeting fell through in consequence of the absence of most of the delegates. From the report read this year we find that eight associations are in union with the Alliance, delegates from six of which were present at the meeting. It was resolved that in future the annual meeting should be held in the first fortnight in May instead of in July as at present.

The subject next considered was Mr. Hine's paper, proposing that the quantities should form part of the basis of contract as much as plans and specification, and that the architect should be responsible for them whether prepared by himself or by his surveyor, respecting which, after some discussion, it was resolved:—"That inasmuch as the bills of quantities are now generally tacitly received as the basis of builders' contracts in the settlement of their accounts, in the opinion of this meeting it would be more just, both to client and builder, as well as more satisfactory to architects, were the bills of quantities formally recognised as part of the contract."

A deputation from the General Builders' Association attended to propose that their society and the London Builders' should meet a committee of the Alliance and the Institute for the purpose of drawing up a model contract, and it was resolved:—"That the Alliance appoint their office-bearers as a committee to hear the representations of the General Builders' Association, and, in conjunction with any other bodies who may be interested, to endeavour to come to some agreement on the subjects submitted for consideration, and to report to the Alliance at its next meeting, or to the constituent societies at an earlier period."

Mr. Plevin's form of contract was then considered, and a resolution from the London Architectural Association against the scheme reported by Mr. R. P. Spiers, and it was resolved that the matter should not be discussed at that meeting. Mr. T. R. Smith, F.I.B.A., was elected president, Mr. T. C. Hine, vice-president, and Mr. T. M. Rickman, F.S.A., A.I.B.A., secretary for the ensuing year. A memorandum was then read by Mr. R. P. Spiers on "Architectural Education," recommending the issue of circulars to the various societies asking for information as to the facilities now existing for architectural education. This it was resolved to do, and the thanks of the meeting having been voted to the chairman the proceedings terminated.

BUILDERS' CLERKS' BENEVOLENT INSTITUTION.

IT is not quite two years since this infant institution was inaugurated by Alderman William Lawrence, M.P., at the public meeting held at the Bridge House Hotel, and on Monday evening last its success as a trade institution was established by the election of two pensioners on the Relief Fund. The chair was taken at 7·30 p.m., at a general meeting of the subscribers and donors at the offices, 14, Bedford-row, by Mr. S. J. Thacker, of the firm of Messrs. Holland and Hannen, and Thomas Stirling and Henry Earle, Esq., and Mr. Alfred Harris having volunteered to be scrutineers, the poll was opened. The result can be seen in our advertisement columns. Although so short a time has elapsed since its foundation, yet so well have the committee upheld the principles with which they started, and so confidently do they look forward to the future, that the election of Monday last may be looked upon as only an instalment of future successes. Throughout their probation the committee have been encouraged by the earnest example and presence at their meetings of their president, William Henshaw, Esq., who sent a letter regretting his inability to attend on this occasion. Although this is the first election and the first public success, it is not the first use that has been made of the funds, a grant having been made a short time ago to the widow of a builder's clerk, who was in urgent distress in consequence of his sudden death. The committee are now busily canvassing for votes for the next election at the Orphan Working School, Haverstock-hill, on behalf of one of the children of Mrs. King, one of the pensioners elected on Monday, and who is left with nine children unprovided for. Proxies will be most thankfully received by any of the committee, or by the secretary, at 14, Bedford-row.

The committee hope that their endeavours to get the institution at work previous to issuing their second annual report will meet with the approval of their trade friends and the public, who they hope will second their endeavours to promote the objects of the institution.

A committee of influential local gentlemen at West Cowes have formed themselves into a company for the purpose of building sea water baths at West Cowes, Isle of Wight, who state in their prospectus that, "in consequence of circumstances having arisen to cause the immediate removal of part of the bathing machines, and the remainder having to be removed at the end of the present season, it has become imperatively necessary that some other bathing accommodation for the visitors and residents should be provided." A site admirably suited for the purpose has been secured at the west part of the town immediately fronting the Solent, upon which they intend forthwith to erect baths of a superior description, the design being made with a view to future extension as occasion may demand. Advertisements have been issued to builders requiring tenders for the proposed works, and the directors purpose to complete the building in time for the bathing season of next year. In making this improvement to their town the directors of the West Cowes Sea Bathing Company appear to be actuated more by the laudable desire of supplying a long-felt want, and of increasing the attractiveness of the place, than by the anticipation of realising large dividends, although there can be little doubt, with sound management, the speculation will be a commercial success.

AMBONE S. MARIA IN ARACOELI ROME.

Cemetery · Chapels, Biggleswade. — J. LADDS AND J. M. HOOKER, ARCHTS.

AMBONE, ST. MARIA, IN ARACŒLI, ROME.

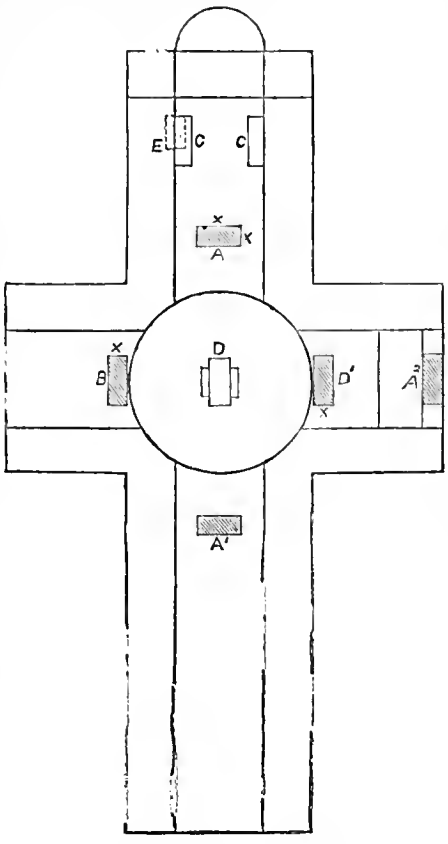
THE church of St. Maria, in Aracœli, in Rome, from which this ambone is taken, occupies the place of a former temple of Juno Moneta, and is situated on the Capitolium, ranking among the oldest and most interesting churches in the Holy City, being A.D. 980, dedicated to the worship of the Virgin.

There are two ambones at the angles of the intersection of the nave and transepts, this one being far the finer of the two, the material being white marble inlaid with mosaic, the prevailing colours being neutral tint, red, and gold. The circular panel, and one above it, in the front view, and the two oblong and large circular panels at the side, are of porphyry, the intervals between the billets round the twisted columns being also of mosaic. The two small circles at the side are of "verde antico." A few details of the carving which adorns it are given, the whole being the work of Laurentius and Jacobus Cosmas. A. P. B.

ST. PAUL'S, ITS QUOIR AND ORGAN.

NOT much excitement, it is to be feared, is to be got out of the merely temporary improvement of a cathedral organ, and many readers perhaps soon weary of so dull a subject; but when it is recollected that all our great cathedral churches are now at this present moment in a rapid state of change and transformation from what remained of their original state to one more suited, as it is supposed, to the present order of things both religious and architectural, it may be there are those who will be inclined to get over this weariness, and to think it well worth while to read and read on till our temples and their organs are in very truth restored, or safely left as they are—Westminster and St. Paul's restored, York Minster left peacefully as it is! Right gladly would I have said something on the nature and effect of the new "stops," tried for the first time last Sunday, now added to the Abbey organ, but it must be left to another opportunity, for the skill of the organist is such that he may *compel* them—the new "stops"—to blend with the *old* organ! In a few weeks we shall both see and hear, for these things take time to do.

In the meantime there is St. Paul's Cathedral to be entered, and, as I think, to be stared at with simple-minded and dumb amazement; no kind of language, however concentrated or diluted, can be expected to do even feeble justice to the work done or now doing in it. St. Paul's is perhaps the best—certainly the most complete—building of which great London can boast. The material of it is real *inside* as well as outside; it stands in the middle of this metropolis of the world, will remain, according to Lord Macaulay, after everything else is gone into lath and plaster rubbish, and is dedicated to the very noblest of human purposes, and has that within it which no other building in England possesses, so that it is well worth a little talking about and thoughtful consideration. We may at starting usefully call to mind a very singular fact connected with churches in these days, viz., that no one has yet proposed to "restore" (in the Gothic sense) any *Renaissance* building. No one has proposed to restore St. Bride's, Fleet-street, or St. James's, Piccadilly, or St. Paul's Cathedral. No one has proposed to found a society for the purpose of doing with all these buildings that which has been done for Westminster, and the Temple Church, and the still more unfortunate St. Bartholomew's, Smithfield. Why not? They are all of them better fitted for their present uses, and far more in harmony with the spirit of the times than the Gothic churches are. It is strange that this subject has not received some little attention; it is well worth it, and might have perchance saved some of the already destroyed or doomed City churches. But our present business is with St. Paul's, its organ and its quoir arrangements. We have added a rough block plan of the cathedral in order that the arrangements may be



BLOCK PLAN OF ST. PAUL'S.

perfectly and clearly understood—so much better than mere descriptions, however accurate.

First, then, it is to be understood that the great architect of this building would never, had he had his own way, have designed such a structure for "reformed" or Protestant uses at all. His mind was of too plain and practical a character for it. All Wren's buildings show that he began always by first asking himself and those for whom he worked what was wanted to be done in the proposed building? and how was it to be done? Thus in the first model of St. Paul's (now in the South Kensington Museum) the whole structure is designed with the intent that it should all of it be utilised and made available for the purposes of "prayer and preaching," but the existing structure is designed and modelled purely on Roman Catholic principles and the Roman ritual—indeed, just as much so as Westminster Abbey itself, and more so than St. Peter's at Rome. The whole of the east end of the church, with the exception of the aisles, is (or rather was before the absurd alterations) screened in closely by the stalls, two admirable iron gates (now, I suppose, destroyed) across which enrtains were drawn, and westward, close to the dome, by the rood screen or organ screen—indeed, as will be readily seen, precisely the same as at Westminster Abbey. This is very curious, as showing how powerfully the Catholic idea influenced the minds of men even in Wren's time. It is quite evident that there was but one idea in their minds as to what a cathedral and metropolitan church should be like, and Wren was compelled to bow to this idea whether right or wrong. Thus not more than a twentieth part of the whole building could be made available for "services." But one thing was accomplished which raised St. Paul's above every other building in England, perhaps in the world, viz., this, that the organ or rood screen, on which Wren was wise enough to boldly place the organ, stood in the best of all possible positions; it could not stand in a better for the effect of *sound*. Whatever the loss and inconvenience experienced in Wren's day from the fact of his being compelled to follow out the arrangements of a bygone time, certain it is that in placing the organ screen and organ where they were (A in the annexed rough block plan) he accomplished accidentally a musical feat perhaps never before equalled. The reader will observe that the screen on which the organ stands (or rather did stand, for both screen and organ are gone) is built immediately between the two westernmost arches of the sanctuary, as we have ventured to call it, the organ standing exactly in the middle of it, and that it is consequently at some little distance from the edge of the dome. I know nothing of mathematical acoustics, now so common an object of study, neither did Wren; but I feel quite sure that were the organ placed right under the dome or even midway between the central eastern supporting arch of it, the musical effect would have suffered, for the sound now has some little distance to travel before reaching the dome, in which and under which the whole of the wonderful effect manifests, or rather did manifest itself. If we imagine for a moment the air as it passes through and out of the pipes of the organ to be coloured, or that visible smoke instead of air passes, we shall readily see how the sounding air comports itself, and what it does, and where it goes, and how in the end it vibrates and trembles in the domical space and dies out or slowly falls into the great nave. The sound and musical effect of all this when the full organ ceased and a full chord of many pipes closed, leaving the vibrating air to do the work, was the very grandest of the very many of which music can so proudly boast. It would be easy to adduce a multitude of instances wherein this most beautiful effect was audible to all, but it would lead us too far into detail; but I cannot deny myself the satisfaction of instancing one special case wherein this triumphant musical feat did its work completely. It has never been heard in Westminster Abbey, for under the incubus of a "Precentor," it happens to be one of the expurgated. I refer to the anthem "The Heavens are telling," from the "Creation," one of Haydn's most happy thoughts, and especially to the close of it, the last two final bars, after the vocal part has ceased; the grand chords are separated by "rests," so that there is a measurable interval between each of the four chords which finish the composition; the notes are short, and thus it is that there is in these short notes and in the intervals between them the opportunity of displaying alike the powers of the instrument and the skill and vigour of the organist, and, what is to our present purpose, the marvellous result of placing the material instrument where its powers can be fully and perfectly manifested. If the hearer of this grand anthem has to thank the composer for having given him so rich a pleasure, it is equally certain that the composer himself might well have thanked the builder of the organ and the architect of the cathedral for having added to his musical thought that which he could never have expressed on his written page.* But, alas! this and so much else is at an end, for the spirit of modern improvement and alteration and "opening out" has been at work, and most thoroughly and effectually destroyed it and all human possibility of repeating it, for now

* I have thus ventured to instance this single effect of the power of a musical instrument when added to what is got from its position in a building, and the form, dimensions, and character of such a building as St Paul's, not because it was a solitary effect, or even an instance of the most useful one produced when the organ stood in its old place, but because it is enough to establish an important and hitherto unnoticed principle in church building, viz., that the *building is a part of the organ*, and the organ a part of the building. I might have said a great deal more, but when I simply add that in the old arrangement, when the organ was at A, the sound from it after the pipes were closed *always* filled the dome and the whole building, it will be admitted that the loss sustained is infinite.

the organ is put away well nigh out of sight and packed between the two piers of the sanctuary (E in the plan), the end arch being "opened out." It is impossible even to imagine a worse position for a large organ to occupy than that now taken up by this organ in St. Paul's, both musically and architecturally; for it will readily be seen that the instrument is literally packed in between the two massive piers, the top of it touching the arch over them, and the bottom of it actually *sunk* beneath the stalls, with the keys below the level of the singers in the quoir, so that the organist himself is literally buried alive! The dull stupidity of all this can surely never be surpassed. Of course the sound is fairly buried with him, not indeed as it would be if coming up from the vaults beneath, but as if packed up in straw and shavings. Fortunately this organ-moving mania is not like ordinary "restoration." *Restoration*, as it is commonly understood, is simply another name for *destruction*, but this organ-moving improvement is remediable, and the time will surely and certainly come when this organ at St. Paul's will be "restored," together with the screen on which it once stood, to the position where the architect of the cathedral and the voice of antiquity so judiciously and happily placed it. It is obviously impossible in a few sentences to do justice to so important a subject as this. Volumes have been written about St. Paul's, and engravings without number made of it, but we are now engaged with the *building* itself, and hope to be able to show that not only was the removal of the organ from its old place a fatal mistake, both musically and architecturally, but that an infinitely better arrangement for the "services" might have been obviously designed. C. B. A.

CLELAND AND MID-CALDER RAILWAY.—COMPLETION OF THE WEST-CALDER CONTRACT.

In a few months hence the Caledonian Railway system will embrace an additional line of something like thirty miles long, and one which cannot fail to prove a highly remunerative connection, while it will become the shortest existing railway route between Edinburgh and Glasgow. The two contracts, West-Calder and Dykehead, forming the Cleland and Mid-Calder Railway, are now both rapidly approaching towards completion. In length the West-Calder contract exceeds twelve miles and a quarter, commencing at the Oakbank Junction, on the present main-line near Mid-Calder, and terminating in the moss of Longford. This contract also includes a branch loop-line, which diverges from the main section at Limefield, traverses in a circuitous direction through various coal and shale works, and again forms a junction with the main section at the termination of the contract. On the above contract are seven large viaducts, upwards of thirty-one span bridges, various arched culverts, as also numerous heavy cuttings and embankments. The whole line is calculated immensely to improve the districts through which it passes. Emerging from the main system of the Caledonian Railway the new line passes through an exceedingly thriving agricultural and grazing district in the western division of Mid-Lothian, pursues its course among the rich mineral fields situate in the north of West-Lothian, and terminates near Hollytown, on the main line, in Lanarkshire. The few remaining portions of the works yet to be completed are being vigorously proceeded with under the superintendence of the eminent contractor, Mr. John Waddell, of Bathgate; the engineers for the company being Messrs. Blyth, of Edinburgh, while the engineering interests of Mr. Waddell are very satisfactorily conducted by Messrs. W. Robertson and Henry Cochrane.

WARMING BUILDINGS BY HOT WATER.

We have recently inspected a house warmed entirely by the improved hot-water apparatus of J. L. Bacon and Co. It was expressly built to demonstrate the efficacy of the principle of warming and ventilating by hot water, and to prove that the absence of fireplaces and chimney breasts and the presence of the pipes were perfectly compatible with all the requirements of comfort and good taste. A difference exists between Bacon's system and some others that are in use. The former employs wrought-iron pipes of a comparatively small diameter, not exceeding 1¼in., whereas a larger size is commonly employed. Upon the whole we give the preference to the smaller size for several reasons. They are more manageable, and can be bent and manipulated with greater facility. They also possess the great merit of allowing the temperature to be regulated with greater precision. They moreover, to use a technical phrase, enable "steam to be got up" within a much less period, and are therefore better adapted for the heating of bath rooms, conservatories, and other special apartments which do not require the maintenance of a constant y warm temperature. But the especial advantages claimed by Bacon and Co. are the impossibility of the temperature of the pipes exceeding a certain limit, and the perfect facility with which the temperature can be regulated by means of stopcocks in every *separate* apartment in the house. This delicate adjustment of the temperature is carried out by the use of coils or of branches, according to the superficial area to be warmed. We may consider this a little in detail. In the first place it is clear that the larger the area to be heated the greater must be the heating surface—that is, the greater the number of pipes. We may easily imagine an area of dimensions so limited that a single pipe laid around it would suffice for heating it to the desired temperature. But this would constitute a very exceptional case, and it is, therefore, the practice to increase the heating surface by arranging a coil or coils of pipes, which are connected with the main pipe, so to call it. Let us suppose now that the hot water is circulating throughout the coil, and, consequently, the temperature of the room at a certain corresponding height, and that it is desirable to lower it; by turning a handle, which acts upon the stopcock, the current of hot water is shut off from the coil and diverted into the main channel, by which it is conducted away. The heating surface being thus diminished, while the area remains constant, the temperature at once becomes lowered. When it is required to raise the temperature again, the handle is reversed and the current directed through the coil, which it traverses and heats before re-entering and passing off by the main channel.

In rooms of limited dimensions, where so large a heating surface as a coil may not be required, the same effect is produced by the introduction of what is termed a branch. It is nothing more than an additional length of pipe branching out of the main pipe, carried for a certain distance parallel to it, and finally rejoining it. By means of the stopcock this additional heating surface can be called into play or cut off from the current of circulation at pleasure. This arrangement is very ingenious, and the simplicity of its action can only be fully appreciated by those who have witnessed it, as we have done, in actual working order. There is no difficulty in laying the pipes in any existing dwelling. They may be placed along the wainscoting, coiled up in pedestals, or laid under the floor, and carried by the joists. In the house we visited, and to which we have already alluded, they were placed behind the skirting, which was of open trellis work, and had a very ornamental and pleasing effect. Mr. Bacon estimates that the highest temperature to which it is possible for his pipes to be raised is about 260 deg. Fah., which effectually prevents all chance of the ignition of wood or other substances by contact with them, even if they were placed in contact, which they are not. Professional men and the faculty generally have long since agreed in pronouncing the practice of partial warming, which is adopted in all houses where open fireplaces are used, as vicious and unhealthy, and especially prejudicial to the weak and infirm. Can anything be more absurd than to have a sitting room heated to a temperature of between 70 deg. and 80 deg., and the adjoining passages and ante-rooms indicating a degree or two below freezing point? Many people object to a fire in a bedroom, unless demanded through sickness, because it is alleged to be unhealthy, but the fact is that it is not the fire that is in itself unhealthy, but the ventilation being defective, it becomes so of necessity. It is a customary plan in many houses to have a stove in the entrance hall, but with this accessory, and with fires in every room in the house, it would nevertheless be impossible to ensure that uniformity of temperature which can alone be procured by the constant circulation of a heated liquid current. A certain length of piping, a small furnace either of brickwork or iron as may be most convenient, a limited supply of coal, coke, or wood fuel, and the casual attendance of an ordinary servant, are all that are wanted to adapt the hot water principle to any present or future dwelling or building. Messrs. Bacon and Co. have applied their principle to several palaces, churches, manufactories, and public offices, from the owners and occupiers of which they have received testimonials of indubitable authenticity.

ENGINE FOUNDATIONS.

That a firm superstructure is essential to the proper working of stationary engines is well known, but it does not follow that this knowledge is always used to good purpose. Circumstances arise, indeed, only too often, under which the securing of a good foundation by any ordinary arrangement is out of the question; and the engineer who lacks the experience and ability required to deal successfully with such cases never fails to disappoint his employers. Not many years since the various portions of an engine were always kept distinct from each other. Thus, a great beam was carried on side walls in no way connected with the cylinder; while the fly wheel was supported on plummer blocks absolutely independent of the rest of the machine. As a consequence, the easy working of the machine depended on the absolute and relative stability of different portions of the structure of the foundation, and the sinking or yielding of any one portion disarranged all the rest. To obviate such results large sums were expended on the construction of foundations for even small engines. If the ground were bad, piles were driven and excavations made to great depths, and the expenditure thus incurred very often succeeded the price of the machine proper. The introduction of self-contained horizontal engines did much to make matters better, but there is still plenty of room for improvement.

Under ordinary conditions a heavy base plate of cast iron bolted on stone blocks answers very well; but it is not certain that under any circumstances such a combination of stone and iron leaves nothing to be desired. If the engine be large, no single stone block can be obtained of proper dimensions, but when two or more are used there is always the chance of irregular settlement and consequent distortion of the machinery to be considered. The plan answers well enough where the ground is good; where it is bad it does not answer at all, or very imperfectly. To say that it is possible to design any one form of foundation which will be applicable to every type of engine under all circumstances is simple nonsense. The engineer must deal with his difficulties as they arise, and he can hope for no assistance from books, because books take no cognisance of engine foundations other than the stone or brickwork blocks ordinarily employed.

A case lately came under our notice where it is proposed to erect a steam engine to drive a rolling mill in conjunction with a water wheel. The only available place for the engine is immediately over the canal leading the water to the wheel. Under such circumstances it is manifestly impossible to erect any foundations whatever in the ordinary sense of the term. Stone blocks and cast-iron foundations are equally inapplicable. It is therefore proposed to carry the engine on two wrought-iron girders spanning the canal and firmly bedded at each end, and it is beyond question that the expedient will answer perfectly if the girders are made strong enough and the fly wheel carefully balanced.

It is to such applications of wrought iron that we wish to direct attention. By the aid of girders of this material engines can be carried as safely on an upper story as on a ground floor, and under any circumstances the weight and strain of the machinery can be transmitted across treacherous ground to solid foundations. A very ingenious application of the principle came under our observation some months since. An eminent firm of engineers in Kent had occasion to construct some heavy machinery for pumping out a dock. The circumstances were such that the cost of the pumping machinery was reduced to a minimum. The system of construction adopted was very simple and efficient. Two long and deep wrought-iron lattice girders were secured some 6ft. or 8ft. apart by cross girders, the space between being

great enough to admit a three-throw crank giving motion to three large pumps. Two steam cylinders were bolted, one on the top flange of each girder, and the girders also carried the crank shaft fitted with a pinion gearing into a spur wheel on the pump crank shaft. So far the whole was self contained, and ready to be put down at a moment's notice. When in place, the ends of the girder furthest from the engine and carrying the pump crank shaft projected over the dock wall. The pumps were supported on a stage below, and no special foundations of any kind were required, the girders distributing the weight of the machinery over a large surface.

In the application of this principle of distribution by the aid of girders consists the best method of dealing with these exceptionally difficult cases, which present themselves now and then to the mechanical engineer. As a rule, it is a mistake to spend money in piling and excavating and putting in brick and concrete piers to great depths. When very heavy pumping machinery, such as that at Abbey Mills or Crossness, has to be erected, the case is different, and although the use of girders may aid the engineer, they will not enable him to dispense in such exceptional cases even partially with deep and solid foundations. But generally speaking, it will be found that by combining horizontal engines with wrought-iron girders costly foundations may be rendered unnecessary although engines of very considerable power are employed. It is impossible to lay down any particular rule to be followed in carrying out this principle. Its success or its failure must depend on the tact, skill, and experience of the engineer. —*The Engineer.*

ARCHITECTURAL SOCIETIES.

The annual meeting of the Students' Class of the Manchester Architectural Association was held on Monday week, at the society's rooms, Lord's Chambers, Corporation-street. There was a good attendance, and much interest was evinced in the proceedings. The secretary's and treasurer's reports were passed, the latter showing a balance in favour of the society. Mr. Alley, jun., treasurer, and Mr. W. H. M. Ward, secretary, were re-elected, and Mr. Redford, A.I.B.A., was made the president, in lieu of Mr. Battye, who retired. The society has been in operation some time and has worked satisfactorily. It seeks to educate students in architecture in branches not ordinarily learnt in office routine. The construction class is held on Monday evenings under the supervision of Mr. Battye; the free-hand drawing class on Friday evening, directed by Mr. Redford; and the water-colour class on Saturday afternoon by Mr. Bagot.

The session of the Liverpool Architectural and Archæological Society commenced on Wednesday evening last with the president's inangural address. The subject for the students' competition this session will be a design for a row of ten 7 yard street houses of three stories; general plan and general design of the front to a scale of 10ft. to 1in.; the front of one house (with section of front wall) to be shown in a coloured elevation to a scale of 5ft. to 1in., with plans of each floor to the same scale. The materials to be restricted to bricks, tiles, and terra cotta. The drawings to be sent in to the council on or before Wednesday, February 3, 1869. The president also offers a prize of two guineas to the student members for the best "Study of Architectural Effect in combination with Landscape," the size of the drawing to be about 16in. by 10in.; the method of execution at the discretion of the competitors. The drawings to be sent in to the council on or before Wednesday, April 14, 1869.

The members of the architectural society of the Archdeaconry of Northampton held their annual meeting on Tuesday last. The report was read at the public meeting in the Townhall, Northampton, after which Sir Henry Dryden read a paper on "The Megalithic Monuments of Brittany." In the afternoon excursions were made to Queen Eleanor's Cross, and to a number of churches in the neighbourhood south and west of Northampton. Another public meeting was held in the townhall in the evening. Amongst the papers read were one on "Symbolism," by the Rev. G. Ayliffe Poole, and one on "The Use of Colour in the Ornamentation of Churches," by the Rev. F. Sutton.

The fourth and last general excursion of the Architectural and Archæological Society of Durham and Northumberland for the present year was held on the 24th ult., at Hamsterley and Witton Castle. Amongst the objects to which attention was drawn were the remains of an old Roman road running from the high end of Witton-le-Wear to a ford in the river below Hamsterley. On reaching Hamsterley the church was visited. The church is cruciform on plan, and consists of nave, chancel, north and south transepts, south porch, and modern vestry on north side of chancel. The whole edifice has been so much altered and defaced that it is very difficult to tell with certainty the dates of the different parts. The earliest portion is the south door or nave, which is Norman. Leaving the church, the party was conducted over Witton Castle. The ancient portion of the Castle forms a square, three sides being formed by a lofty embattled wall, and the greater part of the fourth side being occupied by the keep. The keep was erected by Lord William Eure, baron of Witton, in 1544, and presents the general features of the better class of pile towers so frequently met with in Durham and Northumberland. No trace remains of the chapel, but it is supposed to have stood on the south side of the keep. The new buildings erected by the present owner harmonise well with the ancient structure. At the entrance to the porch are placed two very beautiful early cross slabs, found on the site of Witton-le-Wear station, the railway cutting through what appears to have been an ancient Christian cemetery. After being entertained at dinner by H. Chaytor, Esq., the occupant of the castle, and several new members having been elected, the members of the society returned by rail to Bishop Auckland.

ARCHÆOLOGY.

A short time ago, says a correspondent of a Dublin paper, a number of articles of great antiquity were recovered from the bottom of a lake about three miles from Tullamore. There is an old tradition to the effect that there is a house at the bottom of a particular portion of the lake; and as, during the recent protracted drought, the water became very low, a search was instituted, and a dwelling, in a tolerable state of preservation, was discovered. There were found in it some plated armour, some old urns and daggers of a primitive make. Some of the articles bear inscriptions, which, however, have not yet been deciphered.

WATER SUPPLY AND SANITARY MATTERS.

The prospectus has been issued of a new Limited Liability Company for supplying Shoreham with water. The supply is proposed to be taken from a spring in the neighbourhood. The capital is fixed at £5,000. Mr. Wilson is the company's engineer.

A movement has been set on foot in Walton le dale and the surrounding neighbourhood having for its object the formation of a company for supplying the township with water. A spring has been discovered in the neighbourhood, and if the water (samples of which are now being analysed by Dr Farrol, of the medical department of the Privy Council) should prove suitable, the works will be at once commenced.

The *Medical Times and Gazette* hopes that the statement by Professor Frankland, in the Registrar General's weekly return, of the extreme impurity of the Southwark water will be inquired into by the Metropolitan Board of Works, or the Privy Council, or other authority. The total solid impurities in this water in September are said to have been as 39 parts in 100,000, against an average of 24 in the other Thames Water Companies. Moreover, it is said that much of the impurity was due to common salt. Had some Thames water from between bridges found its way into the reservoir?

Building Intelligence.

CHURCHES AND CHAPELS.

Lillington Church, Leamington, was reopened on Tuesday week. A new south side aisle has been added, the chancel arch has been widened, and an open stained roof has been substituted for the flat one in the chancel. The total cost has been £1,000, and the work has been executed by Mr. W. Ballord, of Lillington.

An encaustic painting by Mr. Cave Thomas, representing the dead Christ, was yesterday fixed in its position in the frieze of the cornice over the communion table in Christ Church, Marylebone. The crucified figure is seen nailed to the cross, extended on the top of an ideal Calvary, where angels, hovering, contemplate the wounds in feet and hands. For force of drawing, symbolical propriety, and local effectiveness this picture is said to deserve comparison rather with the works of French or German mural painters than with the few and unimportant attempts which have been displayed of late years on the walls of English churches.

St. Paul's Church, Clifton, was consecrated on Tuesday week. It is a re-erection of the building, which, it will be remembered, was destroyed in December last. With the exception of the outer walls, the tower, the spire, and the vestry, the church was wholly destroyed. Very few features of the old edifice are reproduced in the new one. The nave and chancel have been lengthened, and the roof of the chancel has been raised, and a new chancel arch, 40ft. high, has been erected, with shafts of red Mansfield stone. The shafts of the pillars supporting the nave arcade spring from moulded and carved bases standing clear of the seats, thus throwing the shafts into bold relief. In the windows, Geometric tracery has been substituted for Flamboyant. There is a richly panelled and carved reredos at the back of the altar. The panels have a ground of gold enriched with a red and blue diaper pattern, and they extend right across the chancel. Sculptured angels holding scrolls with illuminated texts appear above the panels, and a carved cornice of natural foliage completes the reredos, which is surmounted by a stone arcade with polished marble shafts and carved capitals. Messrs. Hansom and Son are the architects. The cost has been £6,000.

All Saints' Church, Scarborough, was consecrated by the Archbishop of the province on Friday last. The plan consists of nave, chancel, and south aisle, and the building is constructed mainly of red brick with sandstone dressings. Accommodation is provided for 900 adults, at a cost of about £4,000. Mr. G. F. Bodley, of London, is the architect, and Mr. J. Barry, of Scarborough, the contractor.

On Michaelmas day the church of St. Michael, Sopley, near Christ Church, Hants, was reopened, after restoration. The building is a cruciform church of Early English date, with Perpendicular alterations. The chancel has been renovated, the circular ceiling in the nave, which concealed a very fine Tudor roof, has been removed, the walls, stone pillars, and arches have been cleansed from many years' accumulation of plaster and whitewash, a new floor raised throughout, and the high old-fashioned pews replaced by open deal seats, stained and varnished. The work has been carried out from designs by Mr. E. Ferrey, by Mr. J. Tanner, of Sopley.

We learn that it is proposed to restore a portion of Tintagel Church, Cornwall—the north transept—in memory of the late Mr. John Douglas Cook, of the *Saturday Review*, who, by his own request, was buried there. The restoration (comprising a painted window "in memoriam") will be effected by his personal and literary friends.

Christ Church, Bessbrook, Co. Down, was consecrated on Tuesday by the Lord Primate. It is built in the Early English style, and comprises nave, north and south transepts, chancel, and tower. There are ten windows filled with stained glass, two of them being memorials.

The reopening of the Roman Catholic Church at Market Rasen took place on the 24th ult. The additions and alterations have been such as have left scarcely any trace of the old buildings, so that it may be called a new church. The architects were Messrs. Hadfield and Son, of Sheffield. The church consists of a nave and north and south aisles. The south aisle is terminated by a tower of the "saddleback" description, rising to a height of more than 70ft. It is crowned by a stone crucifix. At the east end, over the Lady altar, is a window representing the angel Gabriel appearing to the Virgin, from the works of Messrs. Lavers, Barraud, and Westlake, of London.

A new Wesleyan Chapel was opened at Ossett, Yorkshire, on Thursday week. The style is Classic, somewhat freely treated. The plan is a parallelogram, 90ft. long by 60ft. wide, the roof being in one span. The cost was about £4,500. Mr. Holton, of Dewsbury, was the architect.

On Wednesday week the foundation stone of a new Presbyterian Church was laid at Derby. The style is thirteenth century English Gothic, and accommodation is provided for 500 persons. The building comprises nave, side aisles, vestry, heating chamber, and other offices. The external walling will be of white Coxbeach stone, and the window tracery will be of Hollington stone. The pewing is of picked red deal, stained and varnished. The cost has been £2,150. Messrs. T. and H. Herbert, of Leicester, are the contractors, and Mr. J. Tait, of Leicester, is the architect.

On Friday last the new church of St. Augustine, Hagley-road, Birmingham, was consecrated by the Lord Bishop of Worcester. The design of the building is by Mr. J. A. Chatwin, architect; the builder is Mr. Partridge; and the whole of the sculpture is the work of Mr. John Roddis, of Birmingham. The exterior of the building is of Bath stone, with bands of Hamstead and plinth of Darley Dale stone; and the interior is faced with grey Bromsgrove stone. It is proposed to have a spire 230ft. high, the foundation for which is already built. The church will accommodate some 720 persons, and consists of nave, two side aisles, transepts, chancel, choir, and minister's vestry, organ chamber, and west porch. The centre window of the apse is filled in with stained glass, by Messrs. Hardman and Co; the subject is the "Crucifixion."

The foundation stone of a new Jewish Synagogue, to be built and endowed by Mr. Simon Magnus, merchant, Chatham, was laid by that gentleman on Monday last at Rochester. The building and house adjacent for the residence of the Rabbi form an extensive frontage in the High-street. The new synagogue will be from drawings of H. M. Collins, Esq., Queen-street, London, under whose superintendence the buildings are in course of construction by J. G. Naylar, builder, Rochester, and, with the sum appropriated for endowment, will cost £7,000.

BUILDINGS.

The guardians of St. Pancras have accepted the tender of Mr. Henshaw for the erection of their new infirmary at Highgate, for the sum of £36,000. They have also accepted Mr. R. Mann's tender for the erection of their new schools at Leavesden, Woodside, near Watford, for £37,545. Both buildings have been designed by and will be carried out under the direction of Messrs. Giles and Biven, architects.

On Saturday week the foundation stone of a new co-operative store and public hall was laid at Rawtenstall. The walls will be cased with pitch-faced coursed wall stone, relieved with moulded strings of dressed Longridge stone. Messrs. Maxwell and Tuke, of Bury, are the architects, their plans being selected in a limited competition. Mr. James Roberts, of Rawtenstall, is the principal contractor. The cost will be upwards of £6,000.

The second of the series of four relief offices assigned for the parish of St. Pancras has been opened. The first, in Compton-place, has already been described in these columns. The new offices are situated in Leighton-road, Kentish-town, and comprise apartments for the resident superintendent, coal and fuel stores, waiting room, committee room, relief room, bread room, labour yards, stone-breaking sheds, store rooms, oakum-picking sheds, and superintendent's offices. Mr. F. C. Robins, of Southampton-street, Strand, is the architect, and Messrs. Thomas and Sons the contractors. The cost has been nearly £2,000.

TO CORRESPONDENTS.

Notice.—Cases for binding the BUILDING NEWS, Vol. XIV., are now ready, price 2s. each.

To Our Readers.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

Received.—H. L. G.—J. N.—M. and Co.—P. and Co. —C. S. J.—J. B.—J. W. (Cowes).—J. F. and Son.—J. T. —E. W.—J. F.—C. B. A.—T. C.—T. R. (with report).—J. Potts.—J. Gibbs (shall stand over till next week)—S. T. —J. L.—W. W.—C. S.—H. C.—G. G. H.—R. B.—W. H. M.

Correspondence.

BUILDING SOCIETIES.

To the Editor of the Building News.

Sir,—"Fair and Square," whose letter appeared in your issue of the 2nd inst., is, I think, scarcely entitled to the designation he has assumed. Though admitting himself "not sufficiently experienced," he makes observations unfavourable to building societies, and this he does from an acquaintance with *one* "prospectus" only. Would it not be better for "Fair and Square" to reserve his strictures until he is well informed, particularly as he avows himself "an advocate for building societies in principle?" "Fair and Square" also "*believes* that some societies pay less in professional fees than they charge," and this he denounces by the hard word "deception." If what "Fair and Square" "believes" should turn out to be true it is not intimated on whom "deception" is practised. If a borrower agrees to pay a certain sum for legal and survey fees to a society, and in consequence that sum is one-fifth or perhaps one-tenth of the amount usually charged, the arrangement made by the society with their professional officers can be no concern of his, while the professional gentlemen are surely able to take care of themselves. It does not seem clear, then, to whom the hard word "deception" is applicable.

As "Fair and Square" announces himself "an advocate for building societies" it is to be hoped that before he again addresses you he will thoroughly master the subject. If his lucubrations will bear the stamp of candour and intelligence he will merit the title he has taken, and even the thanks of all interested, and especially those of your obedient servant, A Director.

October 5.

Sir,—I am afraid you will think it time that this correspondence should cease, but before closing it I must beg the favour of space for one or two observations on the letters in your last impression.

I could almost be angry with "Fair and Square" for turning the tables on "A Director," whom I looked upon as my best friend in the controversy. His little plea for the societies was so *very* modest that it is with a kind of regret one sees it disturbed. With your correspondent "B. B." I have no contention. The society he refers to as willing to accept £36 per annum for 10½ years in repayment of a loan of £300—something *under* 5 per cent. on the annual balances of the principal—must satisfy the most exacting and scrupulous of borrowers. If he will kindly furnish me with the rules and particulars of the society he alludes to he will do me a service, and I will gratefully reimburse any charges he may be put to.

I might take exception to the tone of the last letter from "S. S." He says I am unfair in introducing the extract I gave last week, that it does not truly represent the working of the societies, and that it tends to mystify the discussion. I reply that the extract in question was cut from the prospectus of the Birkbeck Society, which is one of the best known of any; that it was reproduced in an article in "Once a Week," which adopted it as an exemplification of the principles of the societies in whose advocacy the article was written; and that it is, I submit, a clear and intelligible statement of that principle. Whether it mystifies the discussion I leave to your readers to say; it was inserted for a directly contrary purpose, and because I saw how inconvenient it was to argue on hypothetical illustrations. My question, "Do landlords reap, &c.," follows directly from a consideration of the principle there enunciated.

I have not the *Daily News* to refer to, but I am not clear that your correspondent is right in saying that Mr. Denton was referring to freehold houses. He was speaking of building operations in towns generally, and these, we know, are for the most part on leasehold tenures; besides, he speaks of the principal being repaid during the "period of duration," which seems to make for my view of the case.

After all, "S. S." must excuse me if I claim him as a convert. In his letter of the 22nd ult., he endeavoured to show that, by the aid of a building society, a house rented at £36 per annum could be purchased at a saving of £250. Now he says that a house yielding the average or a satisfactory return of profit can be so obtained by a tenant "without sustaining any pecuniary loss!"—I am, &c., E. Ingress Bell.

October 5.

Sir,—I have read with much interest the correspondence on this question, and with your leave I should like to ask your correspondents if they can explain why the "Temperance Land and Building Societies" can only afford to pay *depositors* 4 per cent. per annum, and require one month's notice to withdraw sums not exceeding £100, while the "Birkbeck Building and Land Society" pay their depositors 5 per cent. per annum, and all sums under £50 are repayable upon demand. I have for many years taken great interest in these societies, and would recommend all members of land and building societies to cut out the letters now appearing from week to week in your paper, and paste them in a book, as I am doing, for future reference. A Depositor.

THE WESTMINSTER ABBEY ORGAN.

Sir,—Being in a position to know thoroughly the organ at Westminster Abbey, will you kindly allow me a little space in your valuable journal to correct some of the errors of your correspondent "C. B. A.," respecting that instrument?

Firstly, then, in the notice of September 11, he says that there are a few pipes in the middle. I presume by that is meant the choir (called by "C. B. A." quoir) organ, which contains six stops, and is in itself a complete organ. Next comes "the final and fatal blunder" (to use "C. B. A.'s" expression), the swell organ. Here your correspondent falls into a great error, as the swell organ at Westminster Abbey is justly famed for its effectiveness. Previous to the dividing of the organ, I believe that the swell box did not open towards the nave, but towards the choir. The comparison of the old and new swell organ is perfectly ridiculous. Further on your correspondent says, "having got the new trumpet, and rid of the old one, which some may remember with dismay." To prevent any misunderstanding it may be as well to say that no trumpet stop has been taken out of the organ, but that of late it had unfortunately been the custom on special occasions to have the addition of a "cornet à piston." Probably this was the dismal old trumpet "C. B. A." alludes to.

Now we come to the September 25th number. Your correspondent here tells us that the whole series of pipes on the "two fronts of this Abbey organ" and the front of the choir organ are "shams." Out of the twenty-four front pipes of the great organ (that on the north side) the ten large ones and the three at the east side are speaking pipes. Five in one of the front small group speak, and the other group forms the door. The seven on the west side are "shams." The whole of the choir organ front are also speaking pipes. The front pipes on the south side of the nave are all "shams," as all the pipes of this organ are enclosed in a box, this being the swell organ. These also are not "wooden cylinders," but metal pipes. Next we come to the "pedal organ." It is well known that this part of the organ is exceedingly effective, the effect being not in the least destroyed by the horizontal position of the pipes—in fact, they are far superior to many 32ft stops that stand in a perpendicular position. I will here refer your correspondent to the work of Hopkins and Rimbault (a work quoted by "C. B. A."), where h will find that Mr. Hopkins speaks in more than one place most favourably of this pedal organ.

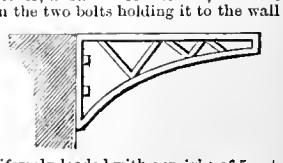
In conclusion, I cannot help remarking that I think it would have been well worth "C. B. A.'s" while to have made himself thoroughly acquainted with the instrument and positive facts, before committing such erroneous statements to paper. —I am, &c., C. S. J.

Intercommunication.

QUESTIONS.

[1052.]—EPICYCLOIDAL CURVE.—Would some of your numerous correspondents inform me what is the exact meaning of the term applied to the curve, and how it is described?—Draughtsman.

[1053.]—STRAINS UPON CANTILEVERS.—In an open-sided cantilever, as shown in the cut, what would be the strain upon the two bolts holding it to the wall supposing



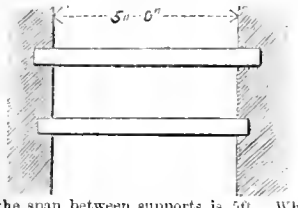
it to be uniformly loaded with a weight of 5 cwt. to the foot run, and the length to be 10ft?—Inquirer.

[1054.]—PAYMENT OF SALARY.—A firm employed a clerk at so much per week, the salary to be paid weekly, but the understanding being that a month's notice was to be given and received before the situation was rendered vacant, by either party. Instead of a month, the clerk received only a week's notice, and was dismissed at the expiration of that term. Has he any remedy against his employers, or must he put up with the treatment?—L. Z. O.

[1055.]—PRESSURE OF WATER.—I have to make a new sluice gate, and would like to know how I am to proceed to calculate the pressure of water against it. The height of the water is 9ft., and the breadth of the sluice gate 6ft. 6in. There is very little current in the stream at any time.—H. H.

[1056.]—COUNTY SURVEYORS.—Could any of the contributors to "Intercommunication" give me any information respecting the proper course to pursue with regard to an appointment as a county surveyor? Is there any examination to be passed, or are the appointments, like many other similar ones, dependent upon interest instead of ability and qualifications?—S. S. J.

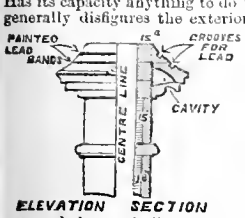
[1057.]—STRENGTH OF CAST-IRON BARS.—Is there any rule for calculating the breaking weight of cast iron bars, placed as shown in the cut? The bars are 4in. by



3in., and the span between supports is 5ft. What would be the safe proportion between the breaking load and the actual load each bar ought to have put upon it?—FITTER.

[1058.]—FILTERING WATER.—Will any correspondent inform me what are the best materials for constructing a filter on a large scale? I have seen charcoal, sand, gravel, and other mediums advocated, but am at a loss to determine which is the best adapted for the purpose.—RESERVOIR.

[1059.]—FACTORY CHIMNEY FLUES AND SHAFTS.—What diameter ought the flue of a factory chimney to be in comparison to the furnaces in connection therewith? Has its capacity anything to do with the blackness which generally disfigures the exterior of chimney shafts, commencing at the summit and continuing down frequently several yards? If not, can any of your intelligent readers inform me of the cause and its prevention? I have long thought that a better method might be adopted in securing those crowning stones of chimney caps which now require to be cramped, by encircling them instead with strong lead pipe (copper rope being expensive), as shown in the sketch. Will this prove a permanent and good holdfast, and would it be liable to be destroyed by the heat from the furnaces?—L. M.

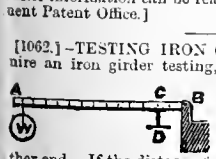


[1060.]—STATIONERS' HALL.—Would you, or any of your readers, kindly subscribe a little information in respect to entries made at Stationers' Hall? Have you to trust wholly upon the faith of your publisher in handing over and settling as to terms, date of publication, &c.? The form to be filled in, as far as I can see, compels this to be done before being able to make an entry? After having once entered, can it be transferred to any other person without again paying the usual entrance fee?—DODO.

[1061.]—LETTERS PATENT.—I have an invention I wish to patent; can any of your "Intercommunication" readers inform me the best method of doing so? and oblige —FITTER.

[Patents are granted for the whole of the United Kingdom of Great Britain and Ireland to inventors only; unless the inventors are resident abroad, in which case patents may be taken by another party as a communication. Not more than one distinct invention can be included in one patent. The cost of a patent for three years, including Government fees and agency (if an agent be employed, which is usually advisable, care being taken that a really respectable firm be employed), generally amounts to about £30. Prior to the expiration of the three years, the patent may be secured for four years further on payment of £53 3s., and may be prolonged for another term of seven years on paying before the expiration of the seventh year, £103 3s. The patent can be abandoned at any of the above stages. Fuller information can be readily obtained at the Government Patent Office.]

[1062.]—TESTING IRON GIRDERS.—Suppose I require an iron girder testing, which will be done in the manner shown in the sketch. Let D be the girder, A B a beam fixed at point B, resting on the girder, with W, a certain weight, applied at other end. If the distance from B to C is 2ft., from C to A 3ft., and the weight applied 2 tons, required the weight actually applied to centre of girder?—CAST IRON.

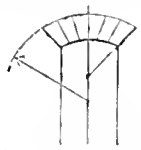


[1063.]—RAILWAY CARRIAGES.—Can any of your readers inform me where I can obtain detail drawings for modern railway carriages, &c.?—J. J.

[1064.]—POLISHED MARBLE AND GRANITE.—Can you, or any correspondent, inform me how to polish marble, granite, &c.?—L. L.

[1065.]—ALGEBRA AND ALGEBRAICAL WORKS.—Would any of your readers be so kind as to inform me those are the best works on Complete Algebra, and also Plane and Spherical Trigonometry, the price, and where published; and if it is necessary to have a complete knowledge of algebra before studying trigonometry, and to what extent? I have already a good work on algebra, by Kerly, but it is very old. I suppose there is a vast difference in the present system of algebra and that of nearly one hundred years ago. I have bought the first part of a work on "Stonecutting and Practical Masonry," which, I am told, is by Nicholson; but as there is no author's name on the book, and not being certain that I have Nicholson's, I would also feel much obliged to any of your readers if they could tell me if the work I have is by Nicholson. The one I have is published by T. Kelly, Paternoster row, and the date underneath the plates is 1848. Or can any of them recommend a better and more modern work on the same subject? I here take the opportunity of thanking "R." for recommending Gwilt's, which I intend to get; and also thank "Subscriber," and am sorry I am not at present in London to look at the copy which he has so kindly taken the trouble to inform me of.—STONEMASON.

[1066.]—CONSTRUCTION OF ARCHES.—Will some kind communicant, better up in construction of arches



than myself, say if the above arch is as strong as one with the ordinary arrangement of voussoirs would be? and oblige—F.

[1067.]—WHEEL AND CHAIN PUMPS.—Will some of your readers answer the following? Throughout a greater part of North America the cottages and small class houses are all supplied with wheel and chain pumps, which I have tested to work well, and answer the purpose even in a severe climate like that. Is there any firm in England who manufactures these ready for putting down? One of their chief merits is that any carpenter can put them in without the aid of a plumber or other class mechanic.—H. H., Great Malvern.

REPLIES.

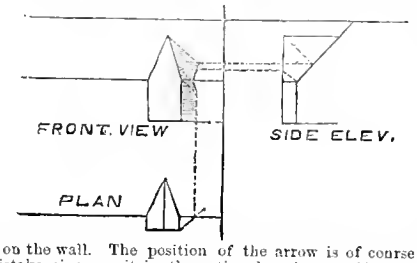
[994.]—LOAD ON CAST-IRON SKEWBACK GIRDERS.—If "Urgent" or "Cast Iron" would refer to my reply to "An Interested One," a week or two back, they will find the principle on which the strains on rectilinear beams are calculated fully explained. In "Urgent's" case, the formula $\frac{a \cdot d \cdot 26}{1}$ is applicable, as in all others; but "Cast Iron," evidently not knowing the principle on which the formula is constructed, is at a loss how to apply it. To find the breaking weight of "Urgent's" girder, divide the sectional area of the girder into two parts horizontally, the lower part being six times the area of the upper (the relative values of the power of resistance in cast iron to compressive and tensile strain being as 6 to 1). The line dividing these two areas will be the neutral axis, the point where the two strains cross, and consequently affected by neither. Having done this, find the centres of gravity of each area A and B, which are the centres of pressure, and take the distance between these two points for d in the formula, $\frac{a \cdot d \cdot 26}{1}$, a being the area of the lower part.—J. L—G.

[1022.]—AREA OF A FIELD.—I read the solution given by "F.," and my first question was—"What has the sixth side done that it should be dismissed from the figure?" He has evidently caught at a straw and defeated himself. I refer him to my letter of last week, for, instead of assisting, I see he needs assistance; and I thank him for specially noting that the method of obtaining the area given by him is not mine.—J. M'NAMARA.

[1022.]—"Young Surveyor" makes a mistake in saying that "the only object of field notes is to plot the survey made." The areas of fields are often required for the valuation of crops and other purposes, for which it is quite unnecessary to plot the survey. In such cases, as I said in my former reply, it is necessary that all the lengths required to throw the field or fields into triangles should be measured. —ANOTHER YOUNG SURVEYOR.

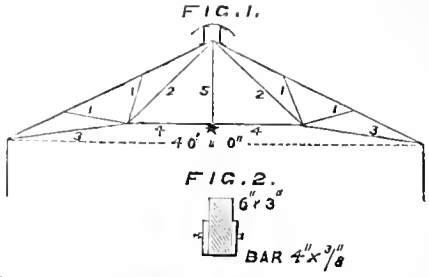
[1025.]—PROJECTION OF A SHADOW.—Will "Draughtsman" allow me to suggest that he will find all the information he wants in the work on "Sciography," of which an admirable notice appeared in the columns of the BUILDING NEWS of September 11.—P. P.

[1025.]—From the angles chosen in the diagram, it accidentally happens that there would be no shadow cast on the roof. I enclose a small diagram, in which the angles are altered, so that a shadow would be cast on the roof as well



as on the wall. The position of the arrow is of course a mistake, since, as it is, the entire elevation would be in shadow. The dotted lines explain the means employed to project the outline of the shadow.—E. S. B.

[1026.]—IRON AND WOOD ROOFS.—Having put up several roofs for engineering workshops intended for precisely the same purpose as that of "Iron *v.* Wood," I can give him the benefit of my own experience. The rafter should be made, as shown in Fig. 2, of timber, with a couple of iron bars upon each side bolted through by ⅞in. bolts. I would advise "Iron *v.* Wood" to discard the old timber truss altogether. The bars No. 1 may be of round iron, 1¼in. in diameter, and burned on to shoes of cast-iron, and united to the rafters by wood screws. Bars No. 2 should be of flat iron, 2½in. by ⅝in.; and those of No. 3 should be in pairs, as the strains upon these are double those upon the bars No. 2. The tie bar, 4, may be 2½in. by



⅝in., and the king rod, No. 5, is hardly needed, and may be 1½in. by ⅜in. I would suggest to "R. G." that he should get a proper design for his roof, and not put it up by rule of thumb, as it will cost him twice as much in the long run.—ENGINEER.

[1027.]—STEEL MAKING.—What "Tubal Cain" appears to require information upon is the difference between iron and steel. This, theoretically, consists in the presence of a certain amount of carbon in the steel, which does not exist in ordinary iron, either cast or wrought. The whole process of the conversion of iron into steel simply means adding to the iron a small percentage of carbon, which is accomplished, speaking generally, by piling up bars of iron alternately with thin layers of carbon, and working them up together. "Tubal Cain" should read some good work on the manufacture of iron and steel.—FER.

[1028.]—THE STRONGEST BRICKS.—The solid brick is much stronger than the perforated. In fact, the latter has very little strength, and should not be used where there is any probability of a heavy crushing weight being brought upon them.—ESSEX.

[1034.]—MEASURING ARTIFICERS' WORK.—There is an excellent little book recently published in Weale's Series on "Quantities and Measurements," by Mr. Beaton, in which I think "A. Beaver" will find all he requires.—STUDENT.

[1038.]—TOWNHALLS.—I can tell "Beginner" that the only "book" he will find on "townhalls" is to be found in an architect's office. He must learn by actual practice how to arrange the necessary accommodation for a certain number of people either in a townhall or a church. No book will give him the information he appears to require.—L. M.

[1039.]—LANDLORD'S TAX AND SEWERS' RATE.—I have read with much interest the dilemma into which "R. G." appears to have fallen; and, in the first place, as he admits that he has signed the agreement for the house which he occupies, let me assure him that he has no redress. In the second place, I consider him very lucky in not having to pay the sewers' rate. It is becoming the universal practice in London and the suburbs to charge the sewers' rate upon the tenant. I pay it myself, and have always done so. Let me now inform "R. G." that, suppose there was no agreement, which is not his case, the only tax which the landlord can be legally compelled to pay is the property tax. This can be recovered at any time by the tenant, should he ever have been made to pay it by coercion or through his own ignorance of the law. The landlord of "R. G." is quite right, and there is no doubt he knows it. —CLERK.

[1041.]—ANTS IN HOUSES.—"Edward Monson" will find the ordinary insect powder, to be obtained at any oil-shop, an effectual destroyer of ants.—H. L. G.

[1041.]—Some further remedies against the annoyance of these insects are suggested by various correspondents of a contemporary. "S. A. K." advises that the cupboards and other places invaded by the insects should be sprinkled with the liquid ammonia used by chemists, and known as "liquor ammoniæ fortis, S·0," "a substance most efficacious in killing black beetles." "A Past Sufferer" has found that if the places frequented by the insects are washed with a solution of alum they will soon disappear. "One who has been tormented with Ants" has found that they disappeared from his pantry after the spots frequented by them had been sprinkled with creosote. "Antidote," who writes from Liverpool, states that his house was overrun with ants during the past summer. He tried various remedies, but in vain, until a few days ago, when he put camphor in small bags, and placed them near the places most infested, and he finds that the insects are fast disappearing. "S. M. O." found that soft soap, mixed with a large quantity of water, smeared in all their haunts, had the effect of expelling them.

[1044.]—THE MEASUREMENTS OF HEIGHTS.—"Reader" will find the rule below will assist him in the use of the aneroid barometer. Assuming the height of the atmosphere to be 27,000ft.: Rule—As the sum of the readings of the aneroid is to their difference, so is 55,000 (or twice the height of the atmosphere in feet) to the elevation required. Example: To find the height of Fairlight Down, near Hastings—

Let the reading of the aneroid on the Marine Parade at Hastings	= 30.05	30.05
Do., on the Down	= 29.44	29.44
Sum	= 59.49	0.61 Diff.

∴ 59.49in. : 0.61in. :: 55,000ft. : 564ft. nearly.

—T. H., Ilfracombe.

P.S.—If "Reader" will send his private address, I will forward him a table, whereby he may see at a glance the heights corresponding to the depressions of the aneroid barometer. Temperature, 55 deg. Fah.; Lower Barometer, 30in.—T. H.

[1044.]—The following table, from the "Board of Trade Barometer Manual," by Admiral Fitzroy, will save "Reader" some trouble in calculating heights by the barometer up to 4,524ft.:—

Height in Feet.

31.0	0	30.0	862	29.0	1,753	28.0	2,675	27 0	3,623
.9	85	.9	950	.9	1,844	.9	2,769	.9	3,731
.8	170	.8	1,038	.8	1,935	.8	2,864	.8	3,829
.7	255	.7	1,126	.7	2,027	.7	2,959	.7	3,927
.6	341	.6	1,215	.6	2,119	.6	3,054	.6	4,025
.5	427	.5	1,304	.5	2,211	.5	3,149	.5	4,124
.4	513	.4	1,393	.4	2,303	.4	3,245	.4	4,223
.3	600	.3	1,482	.3	2,396	.3	3,341	.3	4,323
.2	687	.2	1,572	.2	2,489	.2	3,438	.2	4,423
30.1	774	29.1	1,662	28.1	2,582	27.1	3,535	26.1	4,524

The simplest rule I know is—As the sum of the columns (or the two readings of the aneroid) is to their difference, so is the constant number 52,000ft. to the approximate height. "Reader" must not expect to get correct heights by the barometer except by the finest instruments and repeated observations.—S. W. J.

[1047.]—COLOURING BRICKS.—Bricklayers use a solution of yellow ochre for colouring brickwork.—H. L. G.

[1048.]—THE BUILDERS' PRACTICAL DIRECTOR In answer to your correspondent "Sandyarms," I can let him have a copy of the "Builder's Practical Director," bound and clean, as I have two, and can spare one, and under prime cost, with 6s. 6d. for binding.—J. N., 44, Lloyd street, corner of Cooper street, Manchester.

[1048.]—I have a copy of the "Builder's Practical Director," with supplementary series, bound in one. I will dispose of it for 30s. It cost, I think, 48s., without binding. —Joseph Burnett, Fence Houses, Birtley.

[1048.]—"Sandyarms" inquires where he can obtain the "Builder's Practical Director." He may hear of one cheap by applying to J. B., No 20, Mill Thorne, Halifax, Yorkshire.

[1048.]—Envious gratulations to "Sandyarms" on his escaping so long the clutches of book-hawkers. He can obtain the work of any of them, or through any bookseller (by order), from the publisher, J. Hagger, 67, Paternoster row.—F.

WAGES MOVEMENT.

Work in Edinburgh is very brisk, considering the advanced season of the year; and masons' wages are rising, many of them asking and obtaining 6½d. and 7d. per hour.

With reference to the late operative bricklayers' strike in Liverpool, the annual report of the Master Builders' Association of that town states that they have been so far successful in resisting the demands of the men that the various works throughout the town are progressing favourably with non society men.

STAINED GLASS.

The north-east window in the nave of the parish church of Allensmore, Herefordshire, is now filled with stained glass. The subjects are the Resurrection and Ascension of our Lord, surmounted by the Paschal Lamb. The window is by Messrs. Clayton and Bell, under the direction of Mr. Benjamin Ingelow, architect, of 4, Carlton Chambers, London.

A stained glass window has just been placed in Holy Trinity Church, Sheerness. The subject is Christ bearing His Cross, with St. Paul and St. Peter on either side. The window has been executed by Mr. T. E. Merritt, of Rochester.

STATUES, MEMORIALS, ETC.

A statue is about to be erected on the great Turnplatz, in the Hasenhaide, at Berlin, to Father Jahn, the great apostle of gymnastics in Germany. All Germany is to contribute to the statue, in the shape of stones for the base.

A statue of James Watt was unveiled on Friday last at Birmingham, in the presence of a large concourse of people. It is from the studio of Mr. Munro; the size is larger than life, and it is chiselled from a solid block of Carrara marble. The figure rests on an unpretending plinth of freestone. The cost of it has been defrayed by public subscription, no small share of which was subscribed by the working men of Birmingham.

A monument to the late General Bruce is being erected in Dunfermline Abbey. It is an altar tomb, depicting in bas-relief on its panels the chief incidents in the journey to the Holy Land made by the Prince of Wales under the guidance of the gallant general.

A memorial brass has been erected in the chancel of the church of the Holy Trinity, Stratford-on-Avon, to the memory of the late Mr. F. W. Fairholt, F.S.A. At Mr. Fairholt's death the museum at Shakspeare's birthplace was enriched by a bequest from him of a great variety of valuable archæological gifts from his collection, which he had made during many years' labour. The brass is placed on the north wall of the chancel, a short distance from the poet's tomb.

BUILDING AND LAND SOCIETIES.

The seventh annual report of the Dover District Permanent Benefit Building Society shows that, notwithstanding the general depression of trade throughout the past year, the society's progress has continued, there being now on the books 1,623 shares as compared with 1,513 taken up last year.

The fourth annual general meeting of the Fortieth Starr Bowkett Building Society was held on Thursday week at the Grove-road schoolrooms, Holloway. The report and balance sheet were read by the secretary, from which it appeared that great success had attended the society during the past year. The number of shares issued is 1,114, held by 500 members. There have been twenty-six appropriations since the formation of the society, representing a capital of £6,500, of which sum £1,181 16s. has been repaid. The total receipts for the past year were £2,288 16s. The working expenses for the same period have been £77 6s. 3d., or about 3½ per cent. The report and balance sheet were unanimously adopted, and the directors and other officers for the ensuing year elected.

The sixty-fourth quarterly meeting of the Conservative Land Society was held at the Norfolk-street offices on the 6th inst., when the report of the Executive Committee was submitted, expressing their pleasure in meeting the share holders at the close of the sixteenth financial year, and at being enabled to make a highly gratifying return for the year ending September 30 last, the receipts for the year being £188,342 19s. 6d., and the grand totals £1,288,916 7s. 3d.; the total withdrawals, £328,984 19s. 6d.; the total sale of land, £583,650 15s. 1d., and the reserve fund, £12,153 2s. 9d. The estates allotted since the last report were Upper Holloway, Reigate (Red Hill), and Northampton. As intimated in former reports the land business heretofore carried on by the society will from the present period be transacted solely by the United Land Company (Limited), the respective boards, by co-operation, being in a position to extend materially their operations—the company by enlarging considerably the dealing in land, the society by increasing building and other advances. The four auditors to sit and report as to the accounts and balance sheet to be presented at the annual meeting early in December next were duly elected. The report concludes by the board stating that they will be now enabled to carry out to a much greater extent than heretofore the wholesome provisions of the Friendly Societies' Acts, and that it is impossible to over estimate the value of benefit building societies, socially and morally. The report was adopted and votes of thanks passed to the board. The following directors and members were present:—Viscount Ranelagh (chairman), Hon and Rev. W Talbot, Colonel Meyrick, Colonel Jervis, M.P., Henry Pownall, Esq., J.P.; James Goodson, M.P.; Mr. Currie, Mr. T. K. Holmes, Mr. Newcomen, Mr. Winstanley, Mr. C. L. Grunesen (secretary), Messrs. Goad, Wells, Russell, Farquharson, &c.

LEGAL INTELLIGENCE.

Important to the Building Trade.—Mr. Vann, solicitor, attended before Mr. Newton at Worship street on Tuesday on behalf of Messrs. Browne and Robinson, builders, of Worship street, who were summoned by James Vesch, a bricklayer, for the sum of £1 13s., wages due for work and labour done for them. A question of considerable importance to builders arose in this case, in reference to the liability of builders for the wages of the men employed by sub contractors under them. The complainant stated that he was engaged by a man named Elliott, who was pointed out to him as being the foreman of some works being carried on in St. John's-street road, Clerkenwell, and to whom he (complainant) had applied as a bricklayer, at 8d. an hour, to help build or "run up" a brick wall; on Saturday, the 19th, there was owing to him £1 17s. 6d., of which he received £1 from Elliott, who stated that he could not pay him more, as the firm (Browne and Robinson) had not sent him enough money. Witness worked on the Monday and Tuesday. On the Wednesday he went to Messrs. Browne and Robinson, and was informed by one of the clerks there that it was not the intention of the firm to pay him or the other men to whom money was owing on this "job," as Elliott was a sub-contractor, and, therefore, liable. In cross examination witness denied having heard that Elliott was a sub contractor for the building of the wall, but stated that he had been pointed out to him by the other men as the foreman of the works. Mr. Vann, in answer, contended that his clients were not liable, inasmuch as they had underlet their contract for that particular work to a Mr. Joseph Elliott, of Percival Cottage, High Bath, in Merton, Surrey, who had since failed to continue to carry on the work, and, moreover, had overdrawn his account with Messrs. Browne to the extent of £25. He produced a stamped agreement between Elliott and Browne, which was handed up to the magistrate. Mr. Newton then said he should not receive it as evidence, neither should he recognise any such contract, without Mr. Elliott was produced to swear to it, and he should put Mr. Vann to the strict proof of his defence, which he considered entailed a great hardship upon men like the present complainant, who, because Messrs Browne, to carry on work for which they had contracted, chose to underlet it to an insolvent builder, who was unable to pay the men working for him, were to go without their hard-earned money. Mr. Vann submitted that as Mr. Elliott had overdrawn his account by £25 Messrs. Browne were not to be made liable to any further extent. Mr. Newton did not know anything about Mr. Elliott—did not recognise him; and if Messrs. Browne chose to allow a person to draw more money than he had earned it was their own fault. The case was adjourned for a few days.

Our Office Table.

The Metropolitan Board of Works has accepted the tender of Mr. Wigmore for deepening, reconstructing, and improving the main sewers in Belvedere-road, Lambeth, at the sum of £24,500. The highest tender was £44,800.

The Scarborough Harbour Commissioners in March last advertised for designs for a new western pier. At a special general meeting last week, the first premium, of £50, for the best design, was awarded to Mr. Charles W. Whitaker, of 28, Woburn-place, Russell-square; and the second premium, of £30, to Messrs. Shelford and Robinson, Victoria Chambers, Westminster.

The surveyorship to the St. George's Hospital is vacant by the death of the late surveyor, Mr. Arthur Mee. A meeting of the governors was held on Wednesday for the purpose of meeting candidates, but no decision was arrived at, and another meeting will be held on Wednesday next, after which any gentleman who may have been proposed and seconded for nomination by two members of the Board of governors may canvass for support.

We regret to see it stated that Mr. E. Welby Pugin is at Malvern dangerously ill.

A singular contract has just been entered into with the city of Paris to buy up all the old paving stones for the purpose of shipping them across the Atlantic, where they are to be used to pave the principal thoroughfares of Buenos Ayres and Monte Video. Do some of our suburban vestries obtain their material from similar sources? One would almost think so from the state much of it is in.

With reference to the claim of Messrs. Messenger and Gundrey upon the Clerkenwell Guardian Board, which we referred to in our last, the clerk, at the last meeting of the body, brought up a report embodying the results of the search which he had been instructed to make through the minutes. From what ensued, however, as that functionary was about to read his report, it may be inferred that the guardians are at fault, and that Messrs. Messenger and Gundrey's claim is a legitimate one. Just as the clerk was about to read his report on the subject a guardian was observed to whisper with the chairman of the board, who immediately asked if it were desirable that the report should be read? whereupon the guardian who had been seen to whisper with the chairman said that he did not think the board should supply their opponents with information which might be used against them. He moved that the board should resolve itself into committee to consider the question. Mr. Mence (a guardian who seems to have something like fair ideas of justice) moved an amendment negativing this motion. He could not see what necessity there was for secrecy in the matter. "If Messrs. Messenger and Gundrey had a claim against the board why not meet it fairly and honestly?" The original motion was, however, carried by 8 to 3, and the board went into committee on the question, with what result has not transpired.

The Lundy Granite Company is being "wound up." The company started three years ago with a capital of £100,000; something like £80,000 of this sum has been called up and expended on the works, &c. The first working of the granite on the island was attended with considerable loss, from the softness of the quality of the stone; the quantity recently produced has been of a superior quality, and it is very probable that the work may go on again under another company, or the present one re-organised. The works are at present suspended.

On Tuesday night Mr. J. Scott Russell, C.E., F.R.S., delivered an address at the Birkbeck Institution, Southampton-buildings, upon the subject of technical education. Mr. M'Cullagh Torrens, M.P., occupied the chair, and there was a pretty large attendance. Referring to the subject of mechanics' institutions, Mr. Scott attributed their comparative failure in the country to the fact that they were deficient of the preliminary knowledge which was necessary for them to become popular. The great evil to be deplored was the low standard which, as a nation, we had been satisfied with for the education of our people. It was considered enough to constitute a public school if reading, writing, and arithmetic were taught within its walls. These things, however, did not constitute knowledge; they were merely the vehicles by which true knowledge was conveyed. The same error had been committed by other countries; but those countries had long since awoke from their error, while England still lagged behind. In Switzerland every man had a complete course of technical education calculated to fit him for the duties of life, and a similar state of things he desired to see brought about in England. It was the duty of their governors to help the advancement of technical education by providing them with the best masters and means whereby to acquire the requisite knowledge. Let the members of such an institution as the one he was then addressing bring the matter before the Government, and then perhaps the results which he desired to see might be brought about. The proceedings terminated with a vote of thanks.

Patents for Inventions

CONNECTED WITH THE BUILDING TRADE.

158 R. HEATHFIELD. Improvements in Machinery for the Manufacture of Nails and Tacks. (A communication.) Dated January 17, 1868.

Here the strip of iron or metal from which the nails or tacks are to be made is fed into the machine against a stop. The piece of metal to be made into a nail or tack

is cut off from the end of the strip by a fixed cutter, and a movable cutter having motion in a vertical plane. The movable cutter consists of two parts of unequal size, and having different ranges of motion. During the cutting off of the piece from the end of the strip, the two parts of the movable cutter move simultaneously, and constitute, virtually, one cutting tool. After the cutting off of the piece of metal the larger part of the cutter ceases to descend, but the smaller part continues to descend, and by its motion effects the carrying of the cut off piece to the gripping dies, and its delivery into the said dies for the purpose of being headed. This is effected in the following manner:—Under the smaller part of the movable cutter is a spring arm, and the cut-off piece of metal, on its separation from the strap, is held at the end to be headed between the end of the said smaller part of the movable cutter and the said spring arm, and on the descent of the said smaller part of the movable cutter is carried down between the gripping dies. By the closing of the said dies the cut-off piece is held firmly for the heading process. Before the approach of the heading punch the smaller part of the movable cutter rises, and the spring arm retires from the path of the heading punch by a horizontal motion, when the heading punch advances and heads and completes the nail or tack. On the retiring of the heading punch and opening of the gripping dies, the nail or tack is forced from the machine by a knocker off. The motions of the several parts described are all or mostly effected by cams on the principal shaft of the machine.—Patent completed.

166 J. M. NAPIER. Improvements in Apparatus for Cutting and Dressing Metals, Woods, and other Materials. Dated January 17, 1868.

The patentee claims, first, the application or use of edge tools (of the kind shown and described) with means or apparatus to give rotation or axial motion to the cutting edge of such tools, substantially in the manner shown and described. Second, forming or furnishing circular edge tools (of the kind shown and described) with a spindle or axis to which the tool is either fixed, or with which it is formed, in one piece, such axis or spindle being provided with bearing parts for the spindle to turn upon, substantially as shown and described.—Patent completed.

168 N. H. ROLFE. Improvements in Machinery for Cutting Laths. Dated January 17, 1868.

This invention relates to the manufacture of laths used for building and other purposes from continuous sheets of wood (as produced in scale board and veneer-cutting machines) into strips of the desired width to form the laths. The improvements consist in incising the logs of timber at given distances as they revolve in the veneer cutting machine. For this purpose the inventor mounts a self acting drum or roller over the logs of timber in the machine, the said roller being provided with a series of longitudinal projecting knives or cutters disposed radially thereon an inch or more apart, which are brought to bear on the wood in motion so as to produce lateral incisions on its periphery at the desired depth and distance apart before it approaches the cutting knife of the machine, which then severs the wood in the form of the lath or strip suitable for the purpose desired.—Patent abandoned.

175 B. T. MOORE. A New or Improved Apparatus for Protecting Water-Pipes from Injury by Frost. Dated January 18, 1868.

This invention has reference to the application to service pipes for supplying water to houses or other buildings, either by means of cisterns or tanks, or otherwise, of an apparatus consisting mainly of a cock, valve, or plug, so arranged that, when frost occurs, such cock, valve, or plug shall automatically close the communication between the main and the service pipe, and shall at the same time effect a communication between the latter and an open branch pipe, so as to allow the whole water contained at the time in the service pipe to escape therefrom.—Patent abandoned.

188 F. J. BAYNES. Improvements in Kitchen Ranges, which Improvements are also Applicable to other Cooking Stoves. Dated January 18, 1868.

The object here is to render the use of a comparatively small quantity of fuel effectual. In order to effect this, whilst the upper front bar or bars may be arranged as heretofore to "fall down," the lower front bars, or a portion of them, are connected together into a frame, which is capable of turning on centres at the upper end of it, so that the bars carried by such frame may be turned inwards to or about at a horizontal line, and in that position form a bottom to support a small quantity of fuel near the upper part of the range, and admit of the heat from such fuel passing freely and effectively under the "top plate" to the boiler on one side, and to the oven on the other side, and then, when it may be desired, to have a larger fire for roasting or otherwise; the frame with its bars may be turned down so that the frame of such bars may then hang in a vertical position to form the front of the fire with the fuel resting on the ordinary bottom bars, as in other ranges, or *vice versa*. This frame with its bars may be moved by a shifting lever handle passed into a socket or otherwise, and be held in either position by a drop, catch, or other suitable stop, and the action of the lever or other moving instrument may release the catch. By these means great economy of fuel may be effected.—Patent abandoned.

* Accepted for pipes. † Accepted for laying same.

London.—For the erection of new premises for Messrs. Negretti and Zambra, at Holborn-hill F. W. Porter, Esq., architect. Quantities by Mr. James Williams:—

P'Anson	£9635
Carter and Sons	9570
Mansfield and Company	9099
Patman and Fotheringham	8985
Jackson and Shaw	8660
Conder	8599
Piper and Company	8597
Hill, Keddell, and Waldram (accepted).	8588

London.—For the erection of new Metropolitan Police Courts, Lower Kennington lane. T. C. Sorby, Esq., architect. Quantities by Mr. John Scott:—

Hill, Keddell, and Waldram (accepted)	£6986

New Brompton (Kent).—For the erection of a new Congregational church at New Brompton, Kent, for the Rev. J. Harsant. E. Habershon and Brock, architects:—

Manley and Rogers	£2620
Simpson	2523
Scrivener and White	2169
Naylor	1978
Nightingale	1972
Stump	1950
Falkner	1734
Wilkins	1700

Peterborough.—For the erection of a chapel. J. Wallis Chapman, architect, 14, Great Western-terrace, Westbourne Park, London, W.:—

Nightingale	£4567
Clark	4360
Thompson	4340
Harris	4210
Ward	4200
Fast	4199
Hobson and Taylor	4097
Moss	4000
S. and W. Pattinson	3950
Halliday and Care	3823
Marriott and Company	3580
Bell and Son	3506

Redcar.—For the erection of a Wesleyan chapel and schools at Redcar. Mr. J. Hunter, architect, Bolckow-street, Middlesborough. Quantities supplied. Accepted tenders:—

Scott, Bricklayer's and Plasterer's work	£519 0
Watson, Joiner and Carpenter's work	435 0
Lord, Mason's work	175 0
Harrison, Slater's work	97 14
Kershaw, Plumbing, Glazing, and Gasfitter's work	87 0
Cunningham and Company, Heating Apparatus, &c.	39 0
Guy, Painting and Staining	28 17

Stratford.—For erecting stores in Maryland-street, for the Stratford Co-operative Society. Mr. Henry Ough, architect:—

Pierpoint	£1150
Charlton	1030
Norton and Son	1024
Merritt and Ashby	995

Hearle	976
Johnson	975
United London and Provincial Co operative Building Company	968
Knight and Dustow	949
Rivett (accepted)	892
Morter	889
Keepence	845

West Dumpton (Isle of Thanet).—For the erection of a new wing and alterations to Park Villa, for Mr. Sinclair. Mr. John R. Collett, architect:—

	New work.	Old work.
W. Osborne	£940 0 0	£197
Kelson	889 11 4	170
Duckett	882 0 0	167
Wade	812 10 0	117
Lawson	780 0 0	160
Elgan (accepted)	744 0 0	150

Woodford.—For erecting a detached villa at Woodford, for Mr. Branscombe. G. R. Noble, Esq., architect. Quantities by Messrs. Linsdell and Gillard:—

Rivett	£1793
Piper	1723
Hedges	1690
Hill, Keddell, and Waldram	1637
Perry (accepted)	1625

COMPETITIONS.

India.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

Bletchingley (Surrey).—October 23.—For the erection of a new infirmary at the workhouse. A. R. Stenning, Mitre Chambers, 157, Fenchurch-street, E.C.

Montgomery.—October 15.—For the erection of new wings and other additions to the county gaol. S. W. Poundley, county surveyor, Kerry.

West Cowes.—October 19.—For the erection of proposed baths at Cowes. Mr. Woodman, architect, 17, Prince Albert-street, Brighton.

Stourport (Worcestershire).—October 19.—For altering and reconstructing a bridge over the River Severn. W. Talbot, clerk, Kidderminster.

County of Carmarthen.—October 21.—For certain alterations and additions to the county gaol. Clerk of Peace's office, Llandovery.

Lichfield.—October 23.—The Bishop's Palace.—Repairing, altering, and enlarging the above named building, and for adding a chapel to the same. Rev. F. Thatcher, the Palace, Lichfield.

Northampton Water Works.—October 18.—For a covered reservoir, 150ft by 150ft. by 17ft. deep. Alexander Milne, architect, 2, Gold-street, Northampton.

Southwark.—October 14.—For the erection of buildings at the rear of the workhouse of St. George the Martyr. J. H. Fitch, 13, Union-street, Southwark.

Westminster.—October 21.—For certain drainage works at St. James's Hall, Regent-street, W. G. Buzzard, Vestryhall, Piccadilly.

Portfield, near Chichester.—October 27.—For the erection of a new district church. G. Woods, Shopwyke House, near Chichester.

Sefton Park, Liverpool.—October 26.—For the supply and fixing of iron railing, gates, &c. J. Rayner, town clerk, Liverpool.

Sutton, Isle of Ely.—October 21.—For certain restorations of the parish church. F. Preedy, architect, 13, York-place, Portman-square, London.

PROPERTY SALES.

September 29.

At Garraway's.—By Messrs. Daniel Cronin and Sons.—Leasehold two messuages, No. 112, Pitt street, Peckham, producing £47 9s. per annum, term 33 years unexpired, at £6 4s. per annum—Sold for £245.

At Guildhall Coffee house.—By Mr Millar.—Leasehold house and shop, No 36, John street, Regent's Park, producing £60 per annum, term 53 years unexpired, at £1 per annum—£500.

September 30.

At the Mart.—By Messrs. C. and H. White.—Leasehold eight houses, Nos. 1 to 8, Thomas street, Rodney road, Walworth, producing £140 10s. per annum, term 49 years unexpired, at £16 per annum—£1,020.

Leasehold three residences, Nos. 8, 19, and 20, Doddington grove, Kennington-park, producing £108 per annum, term 27 years unexpired, at £15 per annum—£835.

Leasehold six houses, yard, stable, and buildings, Nos. 2 to 7, Ann's-place, Lant-street, Borough, producing £140 4s. per annum, term 97 years from 18.0, at £25 per annum—£650.

October 5.

At the Mart.—By Mr. Whittingham.—Freehold plot of building land, fronting the High road, Wimbledon—£140.

October 6.

At Garraway's.—By Mr. Fred. A. Mullett.—Leasehold residence, No. 11, Bentinck-street, Manchester square, annual value £120, term 40 years from 1860, at £20 per annum—£920.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

Augustus Salem Dimsdale, St. Paul's road, Islington, builder, October 20, at 11—Arden Binkley, Sittingbourne, brickmaker, October 20, at 12—Henry Venthem, Chapel-street, Bedford-row, builder, October 22, at 12—Seth Benton, Finchley, builder, October 15, at 11—Alfred Pare Jones, Edgware-road, builder, October 12, at 1—Frederick Nash, Alton, plumber, October 12, at 12—Edward Phillips, Leighton Buzzard, timber dealer, October 15, at 1—William White, Poole, builder, October 15, at 12.

TO SURRENDER IN THE COUNTRY.

Jesse Bryan, Burton-upon-Trent, slater, October 19, at 11—Richard Court, Aston, near Birmingham, builder, October 21, at 12—Thomas Holmes, Tranmere, architect, October 23, at 2—William Playford, Woodbridge, timber dealer, October 19, at 3—Henry Mercer, St. Helen's, bricklayer, October 14, at 11—James Moody, Leeds, builder,

October 12, at 11—Godfrey Parry, Rhyl, painter, October 17, at 11—Henry Williams, Redruth, carpenter, October 14, at 11.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

October 23, J. Carver, Wellington, Salop, builder—November 17, W. Tyers, Nottingham, builder—November 3, C. Percival, Liverpool, paint manufacturer—October 20, G. Hanlon, Liverpool, civil engineer—October 22, E. Hanlon, Liverpool, civil engineer—October 23, C. Cochrane, Manchester, builder—November 4, J. Ashcroft, Atherton, nail manufacturer—October 22, H. Clarke, Burslem, plumber and glazier.

PARTNERSHIPS DISSOLVED.

Bellamy and Bland, South Normanton, brickmakers—E. and W. Buckingham, Holland road, South Norwood, builders—M'Intyre and Robinson, Newcastle-upon-Tyne, cement manufacturers—Parkin and Johnson, Bradford, builders—Wright and Son, Old Ford-road, brick merchants—W. and E. Passford, Nottingham, timber merchants.

DIVIDENDS.

October 27, J. Abbott, Manchester, builder—November 4, J. M'Kinnell, Brunswick square, ventilating engineer—October 15, C. Evans, jun., and T. J. Jones, Newport, Monmouthshire, timber merchant.

THE BUILDING NEWS.

LONDON, FRIDAY, OCTOBER 23, 1868.

NATIONAL EXHIBITION OF WORKS OF ART AT LEEDS.

A FEW short hours and the Leeds Exhibition will be numbered as a thing of the past. Five centuries of painting will be unloosed from its walls and will go back to their wonted places, where each can but tell its individual history; they will be broken links of a brilliant chain which has connected this nineteenth with that fourteenth century, reaching back from the days of Tennyson to those of Dante, and spanning over many changes of faith, of thought, of history, of habit, reflecting and recording each epoch as it rolls along. We cannot see such a collection dispersed without a pang of regret and without a fear that we shall never see its like again. The risk of damage prevents those who have once run it being willing to encounter it again, and the want of commercial success which has undoubtedly attended this Exhibition will form both a detergent and an excuse when another is attempted, and, as we look our last on the many fine works which for six short months we have had the pleasure of studying, our pleasure is tinged with the sorrow of parting, and the foreshadowing of the purposes of the building where all this beauty has been comes upon us.

We took much note of the earlier Italian German schools in our columns some time ago, and must now take a brief valedictory glance at the contents of the other galleries, remarking rather the tendencies of schools than the individual merits of its members. Our own English school seems to have sprung from that political and polemical union which the similarity of faith and fear of the Spaniard brought about between England and the Netherlands. The names of almost all the earliest representatives of art in England are of Low Country origin. Holbein, Antonio, More, Vandyke, Rubens, Lely, Gerbier, and Kneller painted and were honoured here, and the great portrait artists of that great portrait-painting country found favour and fortune both in England. Nor did they do only this, but they laid the foundations of that love of the art of painting in England which has grown with our national growth and made us the greatest picture-buying race in Europe—we do not say the most discriminating judges, or the wisest patrons: if so, we should do more than buy; we should found schools of painting and honour our artists, we should sit upon South Kensington and not be in a hurry to rise up again, and we should insist upon the Royal Academy of Arts being an institution deserving of its name. For these things we must wait till such a future when the memory of the Cole shall have merged into the ashes of the great, and when the holders of the proud finials of R.A. shall have been earned by artists whose chiefest honour is an atelier crowded by pupils, and be looked upon more as the consequence of having made a name than as a means of making money. We have faith in the good time coming, a faith strengthened by the pictures on these walls. We see how, from such small beginnings, the English school has grown into a young vigorous forest of untrained trees, sadly in want, it is true, of pruning and cultivation, each growing as it best can, uncared for or uncultivated, until it has risen so high as to require no care and become too stubborn to need or to heed cultivation, yet, in spite of all, producing much pleasant blossom and perhaps still more fruitful seed. In the English school past and present we note a steady progress in the love of truth and love of colour. We see the tricky and impossible draperies of the German school laid aside—Hogarth, Gainsborough, and Reynolds painting people as they were. We see the false piling up of rock, wood, and water, once yclept a classical landscape, pass away, and Constable sitting down in the quiet Suffolk lanes with a firm belief in Nature and a humble attempt to copy her. Later still, we see that truly great man whose memory is in danger of being buried under the indiscriminate praise of Mr. Ruskin. We see Turner leaving the false blacks and browns of the Dutch marine-painters who won his maiden love, and coming here to Leeds, working in the old ruins of Kirkstall, wandering thence up the valley of the Wharfe and over the rolling wolds of Yorkshire, studying and recording the frowns, the tears, the smiles of Nature, and teaching a lesson, then unlearned, that landscape art, to be good, must be true. It was the same tendency which the erring Morland recorded on his works; wrong as he himself was, his art was right, but he was too weak to obey its dictates, and though it was bad for the old bottle, the new wine was put into it. Yet luckily the wine was not lost. Wilkie and Mulready exemplified this vernacularisation of art which wrought so great a change—a change necessary to make art a living language, in which she could speak without the aid of a false interpreter, and a change which has indelibly impressed itself upon us. Haydon offered himself a sacrifice. Blake and Martin went mad. Barry and many another died in poverty and distress, because they could not see this tendency. They spake to the people in a language they knew not, and the people hardened their hearts against them, and their phase of art passed away. Thus was the love of truth growing. Meanwhile a new thing arose—no, not quite new—nothing is; but, after having slept a few centuries, the art of painting in watercolour awoke again, and at Leeds we could well and amply trace out how from tinted pen-and-ink sketches this art grew in England to that fine pitch it has now reached, or rather to which it culminated some time back, for of late years the tide has ebbed somewhat. Watercolour nowadays attempts to outvie oil in impasts, and loses its own soft transparency, for the loss of which no amount of body can ever compensate. It, too, commenced in greys and neutral tones, fearing to do more than indicate the hues of Nature, and never attempting to outrival them, but in both the oil and watercolour painters of the yesterday of art we find the love of colour coming in strong upon them, and, bursting down all the traditions of the elders, glows upon canvas and paper with gorgeous brilliancy. Take the early studies of Mulready and look at his latest works as examples. See, as we have done at Leeds, the low-toned brown efforts of John Philip, and his full luscious colour at the end of his days. Look at the quiet hues of Faed in his early works, and see how he has followed this present tendency. A tendency there is, perhaps a desire, amongst the younger artists of the day, to try and stop, but they too are young now, and the feeling will overwhelm them, and they will be brighter colourists than those whom they now condemn. We are becoming Venetian traders, almost republicans, but by no means of Spartan breed. The wealth, the love of luxury, the pride of the eye in them, as in us, found its chief vent in colour, and no doubt the pre-celebrated future New Zealander, with a Maori Murray under his arm, will draw a very pretty parallel between us some day in some antipodean BUILDING NEWS. Thus much we learn from our own school as exhibited at Leeds. In the modern French school we see how ineffectual were the labours of her earlier followers of Poussin and Claude, for, in spite of the labours of Joseph Vernet, no school of landscape formed itself in France. The labours of David and the classical tendency of the Consulate and the Empire threw France back from the study of Nature. She was not ambitious enough for them, and perhaps too modest; but with the overthrow of her military power came a truer mood. Her mediæval history was swept away. Her recent one was ignored, and nothing but the everyday life of her people was left to her, and hence arose this *genre* school of painting, which, in its very excess, now distinguishes France. How lovingly Edouard Frère wanders about amongst the peasants of Ecouen is shown by his charming little transcripts of their daily life, keeping his heart green with their children's joys and sorrows, and making us feel young again as we contemplate them. Daverger, his pupil, follows in his wake, and imitates his master in the closest manner, showing how much the scholastic principle of French art influences its artists. As another instance of this look at the works of Ruiz Perez, whom death has too quickly taken from us. See how closely he imitates his master, Meissonier—at least, approaches as near as anyone can to such incomparable finish.

We do not suppose that any picture was ever more highly wrought than that "Chess Players" of Meissonier here, painted at a time when his hand and eye were doing him their best service. It is a miracle of manipulation, and requires a microscope to develope all its beauties, but we should regret to see many such. We admire it in one man, but we should think it waste in many to spend so much life to do so little. It is this littleness which is the bane of French art just now, and the art of painting is not the only one which suffers from it. High finish, exact detail—exquisitely pretty and equally soulless—her painting, architecture, and literature are all alike, without one scintilla of poetry to light up any one of them; and, instead of diamonds, we have exquisitely finished paste. Her artists are very learned and very clever, but there are few of them who strike upon a deeper chord than pleasure. In Belgium we find more earnestness, and the works of Gallait make us thrill with emotion. Who can stand before that noble "Art and Liberty" and not feel his breast inflate, his heart beat quicker, nor find an emanation from that patriot face light up his own? or who can look upon that sad, stern scene where Counts Egmont and Hurn hear their death sentence without feeling how much liberty of conscience and religious freedom owe to their memory? In these works of his we forget the artist. Never do we say, "How did he get that effect?" or wonder "what do he that is." The artist, like us, forgets himself; his subject, not his art, is all he thinks of. Painting is but the vehicle of his mind, and so occupied are we with all he has to tell we never noticed how he told it. Great are Gallait's triumphs, but the greatest of all is his victory over the vanity of his art. Very different are the works of Leys; yet these two men are perhaps doing more for the foundation of a national school of art in Belgium, which one day may help Belgium to keep herself still a nation. The learned research of Baron Leys, and the inculcation of exactitude in study, form an excellent combination with the fervour of Gallait, and this combination we find impressing itself on Belgian art. We cannot pass by the works of a coming man, Alma Tadema, who, though a Dutchman, is a poet, a painter, and an archæologist. His works astonished us in Paris, and we are glad to meet them again here, and if Baron Leys had no other claim upon posterity they would venerate his memory as the tutor of Tadema.

German art is not represented in its higher walks—its chiefest efforts must be studied on the walls of its buildings, but in it we see a growing tendency to abandon the stilted academic and to study Nature more; whilst from the cold north come that mysterious combat of Tideman's, which so astonished us in 1862, and many low-toned, silvery landscapes from the fells and fiords.

Nearly three thousand paintings have claimed our notice in these nine galleries at

Leeds. Upwards of 600 artists—each a man above his fellows—have spoken to us from their walls, and have, we trust, spoken not in vain; but the lessons they have taught have, we hope, been learned by many, and will, we believe, be treasured long after their works have been dispersed. It is but on rare occasions that we can thus compare and contrast the works of the various schools, and these occasions should be made the most of and most deeply studied.

Although nine-tenths of the Exhibition at Leeds was devoted to paintings of such great interest, the other portion fell but little behind it, for we found a very fine collection of enamels, extending from the *champlevé* and *cloisonné* work of the thirteenth century down to the latest period of the translucent enamels of Limoges, and being particularly rich in the lustrous but somewhat gaudy works of the Court family. Few of them, however, were new to us: and, indeed, this remark applies to the whole range of objects exhibited in what is termed the Museum of Ornamental Art. Old friends are ever welcome, and though some of the objects here have appeared in almost every exhibition of the kind, from the first small essay in the rooms of the Society of Arts, in 1851, down to the recent loan collection at South Kensington, yet they are welcome still.

Ceramic art has been particularly well represented in the works of Wedgwood and the earlier works of the Yorkshire potteries; but of the ancient works of this class a small yet carefully selected series of Etruscan vases was the sole representative.

Early embroidery and needlework and fine examples of lace took back the mind, if not to the days of Penelope, at least to those of many similarly situated ladies in our early history, whose husbands wandered on their way home from the wars; and of the jewellery and personal adornments of the past there was a fair and interesting show. Still it was the grand collection of paintings which will make the memory of the Leeds Exhibition live in the minds of those who saw it; and it will be an era in the lives of many who have here for the first time felt how important a passage in this world's history is the record left by its pictures.

We have got all we can from them and therefore we ought to forget them, but we cannot do so, for though we are getting old and approaching the end of our fifteenth volume we have not yet learned some of the ways of the world, and therefore we cannot forget the labours and the kindness of those whom we have encountered at Leeds, and our last pleasing office is to record our appreciation of many ably fulfilled but unseen duties of its chief Commissioner, Mr. J. B. Waring, and his indefatigable assistant, Mr. Redford, who formed so goodly a collection; the intelligent care of Messrs. Saunders and Lefevre, the superintendents of the English and foreign galleries; and the erudition and painstaking zeal of Mr. James, the superintendent of the catalogue, and compiler of the biographical notices which form its appendix.

LONDON TERMINAL STATIONS.

BUILDINGS are of three kinds—buildings, structures, and perpetrations. Of the latter are for the most part railway constructions of every description. In an age boasting of its rapid improvements, and but too much inclined to underrate the achievements of yesterday, it behoves the critic to be careful that he be not carried away by the mere popular feeling of the hour. There is no doubt that we have reached a point where we attach undue importance to certain architectural works merely on account of their immense proportions. It has always been a mystery to us why mere size should impress reasonable beings in the way it unquestionably does. It is common enough to hear the expression, "Its mere size gives grandeur." If so, the gasometers at Whitefriars and King's Cross are grand; the floating dock "Bermuda," recently launched at the Isle of Dogs, is grander still. We are led to make these remarks from observation of the tendency of railway engineers to vie with one another in giving to their works a colossal character rather than one commensurate with their actual importance. Mr. A. builds a bridge or a station, Mr. B. caps it with a larger, Mr. C. surpasses both, and Mr. D. out-Herods Herod. The consequence of this rivalry, which is nothing more than the outward expression of the sentiments of that eminent firm, We, Us, and Co., is that the metropolis is permanently disfigured by structures of gigantic size. We should be glad to know, for instance, what the Thames has done that its banks should bear such structures as the termini of Charing Cross and Cannon-street, or that its bosom should be spanned by the bridge leading to the latter—without question, regarded from every point of view, the ugliest bridge in the world. It was, indeed, an evil hour in which the South-Eastern Railway Company gained permission to obstruct by their Cannon-street Station the beautiful view of St. Paul's which used to be obtained from London Bridge. It is bad enough that railway companies should have the monopoly of traffic, but it is worse that they should have the monopoly of the prospect and the power to mar the beauty of the metropolis. It is idle to plead the exigencies of traffic. The stations having most traffic are the most elegant; at all events, the least pretentious. To begin with the most elegant, let us examine the terminus of the Great Western at Paddington. It is in three spans, crossed by two transepts, an arrangement which gives it intricacy and picturesqueness, and conveys an idea of something approaching to comfort, if such a thing can possibly exist in connection with a railway terminus. The girders are pierced in the web with various devices; the columns are light and of Moorish character, and the whole is airy and elegant. The bases of the columns deserve particular attention, and we may here remark that, in the opinion of many excellent judges, the Moorish style is the very best that can be adopted for iron architecture. The Classical Orders are exclusively for stone. Even the slender Corinthian or Ionic shaft, in iron, is manifestly a sham, and our common sense rebels against it. How, then, is it with the stout Doric column with its massive capital? An example of the Doric column in iron may be seen in the Cannon-street bridge. It is a thing which once seen will not be soon forgotten. To revert to Paddington, the supports to the roof are in the way of nobody, the ventilation is perfect, and the roof is so low that it does not obtrude itself upon the neighbourhood; if it did it would not be an offensive object. While Paddington terminus exists let no one say that any other must be either huge or hideous. The late I. K. Brunel has the credit of the design. The construction of the Ark or the building of Solomon's Temple might with equal propriety be attributed to him. The real author is practically unknown, but Mr. Brereton is acknowledged to have been Mr. Brunel's right-hand man as regards ironwork, but the exact share of praise he deserves for the design we are unable to determine.

From the most comfortable let us pass to the most comfortless of the London stations, viz., Victoria. This must certainly be intended only for temporary use, and with this hope we will dismiss it. A goods shed, a barn, or a brickfield are scarcely subject for architectural criticism. Charing Cross is the station next in order. This is one of the monstrosities which it seems to be nobody's business to interfere with while in progress, and everyone's duty to condemn when completed. It is very long, very wide, very high, and very hideous. The walls afford capital accommodation for advertising boards, and this is the utmost that can be said in its praise. Were the walls lower and the roof a complete semicircle it would have been less offensive, but as the former are of immense height and the latter segmental the effect is, whether seen from within or without, about as bad as can be conceived. It is, indeed, rivalled by the Cannon-street Station, and it is difficult to award the palm of supreme ugliness to either without doing wrong to both. Perhaps the best way of settling the matter would be to decree a palm to each, as was done with regard to the champion's belt, when contested for by Messrs. Sayers and Heenan some lustre and a half ago. That this immense height was a positive disadvantage we ourselves were witness on the occasion of the fire which last year did so much damage, and which the fire engines could not reach from the platform. The large span is not justified by the plea of freedom from obstruction as to columns for support of two or more smaller spans, inasmuch as the platforms are both here and at Cannon-street encumbered with lampposts, which are to all intents and purposes as much in the way as a column to support a girder. Neither is it justified on the score of superior ventilation. We consider both these stations positively ill-ventilated, and with this we dismiss them. Crossing the bridge and passing under the line, the departure platform of the South-Western Railway is soon reached. This station has the peculiarity of being on a curve. It is in three spans similar to those at Paddington, and the lamps are suspended, not set upon standards. There is no pretension to elegance or ornament, but it accommodates its traffic, is well ventilated, and does not offend the eye, and this is more than can be said for a great many buildings in the metropolis, whether railway works or other. Neither Blackfriars Station nor Ludgate-hill are termini properly speaking, but both are worth looking at. If they have no great merit they are not needlessly obtrusive. They are on a high level and cannot choose but be high, but the station itself above the platform is as low as is consistent with its purposes. The excessive use of bricks of different colours is, however, to be deplored, and we could have wished to see buildings of less fanciful architecture at the ends of such noble bridges.

The London Bridge terminus of the London, Brighton, and South Coast Railway is now completed. The outside, or rather the front on St. Thomas-street, does not display any architectural talent, though it betrays some considerable effort. The interior is in two spans, the one segmental-headed and the other consisting of a plain ridge roof at right angles to what may be called the main span. The effect is certainly bad, and we cannot see any necessity for such an arrangement. The columns supporting the roof are certainly larger than is required, and the bases are perfectly ridiculous from their size. The designer evidently does not look on columns as an obstruction to a platform, nor do we. They separate people into two lines and prevent jostling; they form spots where people can harbour and exchange a few words without being elbowed, and where a bag or parcel can be temporarily deposited with less risk than on the open platform. The ventilation of this station is perfect, though the roof is so low that it cannot be seen from without. Broad-street Station comes next in order. The visitor will be struck by the extreme lightness of the interior. It seems as though the limits of iron construction had been reached in this building. It is in two spans, and is well ventilated. The columns are like those at London Bridge station, clumsy as to the bases—the worst fault a platform column can have. There are eight lines of rails. The roof is low, but the ventilation is perfect; semicircular openings are left on each side near the plate. The exterior is superior to that of any other London station, and exhibits considerable taste. Thence to King's Cross by the Metropolitan train at Moorgate-street is but a step. Here we see an instance

of the explosion of a too readily adopted constructive principle. For a long time the circular ribs, built up in the laminated method, and consisting of five two-inch planks bolted together, have been losing their shape. In other words, they have sunk at the crown of the arch, and at the present moment the travelling scaffolding is fixed in its place for their repair. There is no doubt that engineers can do wonders; but how anything short of removing the ribs one by one and replacing them with others of iron or some better construction of timber can render the roof safe we do not at present see. This station has eleven lines of rails. We now come to the Midland Station, opened on the 3rd of the present month. In its present unfinished state a fair opinion of its merits can scarcely be formed. The construction is excellent, the diagonal rib being especially adapted to resist strain of wind or racking, to which, however, but for its overgrown size it would never be exposed. The front, by which we presume is meant the hotel, is in course of construction, designed by Mr. G. G. Scott. Judging by the character of the work on the ascent from the Euston-road, we do not expect much. The parapet of a thoroughfare for foot passengers should present no sharp angles, no delicate corners, no crafty mouldings inviting wanton injury. This parapet is an ingeniously devised out-door museum of all these objectionable features.

With a glance at the old Euston-square station of the London and North-Western Railway we will bring this paper to a close. It was built when railways were almost in their infancy, and may be said to consist of a *propyleum*, a hall, and a statue to Stephenson, with many lines of rails on either side. This station is, perhaps, too low, but we are not aware that complaints are made regarding the ventilation. There is really no valid excuse for erecting the immense spans of roof without which the present race of engineers deem no station complete. We think we have satisfactorily shown that neither the requirements of ventilation nor the demands of enormous traffic necessitate enormous roofs, and we have in vain sought for a justification on any other grounds for the growing custom of employing them.

PREPARATION OF OIL PAINTS.

At the present time chemists and philosophers acknowledge the existence of about sixty bodies or substances to which they give the name of elements. The bestowal of this term upon them implies that all the efforts of human skill, all the power of science, the fertility of invention, and the resources of the laboratory and the workshop have been unable to separate them into any components. Adopting the atomic theory, one of their molecules might be truly said to be one and indivisible. To the various combinations of these elements quantitatively and numerically are due the existence and formation of every natural substance that is to be found, and which in contradistinction may be appropriately called compound bodies. These latter may be divided into two separate classes, which are constantly confounded, and concerning which erroneous opinions are commonly entertained. A mixture, in the strict chemical sense of the word, is not a compound body unless the union of the component parts is attended with a mutual affinity stronger than that produced by mere mechanical means. As an example we may take alloys, which are not simply mechanical mixtures but *bona fide* compound bodies, the separate elements of which possess a strong chemical affinity for each other. It has also been proved that the different paints employed in the decoration and preservation of timber, iron, and other constructive materials, are not simple mechanical mixtures of oil and mineral substances but true chemical compounds, and endowed with that closeness and intimacy of union that invariably attends similar combinations. Recently, M. Hugoulin, holding a scientific appointment in the French navy, has turned his attention to this subject, which would otherwise possess little interest or importance were it not that it may be rendered of great benefit to the industrial arts. By conducting the preparation of paints upon a chemical rather than a mechanical principle, it is stated that they may be manufactured in any quantities in a very short space of time, and in a simple and economical manner, which would dispense with the greater portion of the heavy and expensive machinery at present required.

The French navy has ordered this new process to be examined and reported upon by a special commission, but as the result will affect the public equally well as the Government, M. Hugoulin has made no secret of the matter, and anyone may readily satisfy himself of the fundamental principle upon which this new process is based. Make a small cake, of a very fluid constituency, with some water and a certain proportion of any of the following ingredients:—White zinc, minium, or lamp black. Add to this cake a quantity of linseed oil, the proportion of the latter depending upon the ingredient employed. If zinc be used the proportion of oil will be thirty-two parts to one hundred, if minium only five and a half, and for lamp-black one hundred and ten parts will be required to one hundred of that substance. The mixture having been made it should be well stirred with a spoon or a spatula, and after a few minutes the oil will be found to be chemically united with the mineral substance, and the water to have separated and float upon the surface. This circumstance is manifestly due to the principle of "elective affinity," by virtue of which the mineral substance leaves the water and unites itself to the oil. The water having been drawn off, the cake is then consolidated and pressed something after the manner in which butter is made. The process can only be applied to certain mineral substances, among which chrome yellow is included, but it appears that those minerals to which it is applicable are those principally used in the manufacture of oil paints, as practice has demonstrated their efficacy as protectives and preservatives for timber and iron exposed to the action of the weather.

Although the experiment we have mentioned is sufficient to indicate that the chemical theory is the correct one upon which to base the manufacture of oil paints, yet it might be asserted that it is but an experiment and incapable of receiving that extension necessary to constitute it a practical success. A little reflection will prove that this would be an erroneous view to take of the process. It is equally adapted to a small as a large scale. It would be impossible, and at the same time undesirable, to enter in our columns into the details of the proposed new system of manufacture, but a brief outline will suffice to show the practicability of the intended operations. If we imagine the colour or mineral substance after being finely powdered, mixed with a large quantity of water, and then passed through a fine sieve or strainer of silk, there will remain upon the sieve but a very small quantity of the colouring matter. This residue, whenever after successive strainings it may have accumulated in sufficient quantities, can be repulverised in a mortar and ultimately utilised.

One of the chief advantages claimed for the sieve or strainer is that it arrests and separates from the pigment many foreign substances, such as small pieces of wood, timber, and other materials. This is not completely accomplished by the cylinders and machinery used in the ordinary manufacture of paints. The foreign particles are cut up very small, but they are not crushed, and the consequence is that, when the paint is applied, after a short time asperities and blisters rise to the surface, occasioning much disappointment to the workman and damage to the appearance of the work. The mixture, after passing through the strainer, is deposited in a tank, reservoir, or receptacle of some sort, where it may remain, if desirable, for some months. After drawing-off the greater part of the water, the proper proportion of oil is added, and the mixture thoroughly agitated. The result is that the cake commences to form, and is precipitated to the bottom of the receptacle. It is then pressed to drive out the remainder of the water, and although a very little may permanently remain, yet it will not affect the value of the paint or injure its application. In fact, it rather assists it in this respect than otherwise. The various and successive steps of the whole process may be summed up as follows:—The action of the water facilitates the minute division of the mineral substance or colouring matter; that of the strainer arrests all foreign particles and impurities, while the extreme degree of division to which the mineral has been brought favours its ultimate combination and chemical union with the oil. By virtue of its specific gravity the newly formed pigment, insoluble in water, separates spontaneously. It should be borne in mind that in its original state lamp-black will not mix with water, but the mixture may be successfully accomplished by previously treating it with a small quantity of alcohol. Also, grey zinc must be perfectly dry when undergoing pulverisation, or it will get sticky and clog, instead of being reduced to powder. This arises from the fact that a partial and incomplete oxidisation is set up by the presence of any damp. Viewed in a hygienic light, this method of preparing oil colours is superior to that in ordinary use, as it in a great measure obviates all danger arising from lethal emanations, against the baneful influence of which the workman in vain closes his mouth and covers his nostrils.

BRICKMAKING IN AND ABOUT MANCHESTER.

In April last the Manchester Society of Architects appointed a committee of their members to consider and report on the methods of brickmaking in that neighbourhood, and to make suggestions with the view of obtaining better bricks than those in general use. The committee have now issued their report. Their inquiries led them especially to investigate the following points in connection with brickmaking, viz.:—1, regularity of shape; 2, uniformity of size; 3, the size to be recommended as a standard; 4, uniformity of material; 5, density; 6 and 7, power of absorbing and retaining water; 8, methods of manufacture; 9, price.

Best stock bricks are described as generally being all that could be wished for as to colour, shape, and regularity of quality, and the report in these particulars is more specially directed towards improvements necessary for the production of a better class of common bricks. Preference is given to machine-made rather than to hand-made bricks for ensuring regularity of shape. They alone combine the qualities of true and parallel surfaces and general rectangularity, though they seldom maintain a good arris. Hand-made bricks are almost all defective in the above requirement, a large proportion being warped, bulged, rough-faced, and with very irregular arrises, principally arising from indifferent tempering of the clay, neglect to pick out stones, the use of so soft a material in moulding that it becomes distorted in handling, the rough surface of the drying ground, want of protection in drying, and the haphazard modes of burning. To the method of manufacture is also ascribed the want of uniformity in size. It is suggested as obvious that different-sized moulds should be used for different kinds of clay, so as to produce bricks, when burned, of uniform size. The introduction of machinery without graduating the

sizes of the moulds would not prevent the production of large bricks of open clays from full-sized moulds, which are preferred by certain classes of builders. The committee consider it a question for consideration whether stiff clays might not be rendered more open by mixing a more loamy clay or breeze with them, as is done in London and the Midland Counties.

The size recommended for bricks when burnt, so that all shall be uniform from wherever procured, is 9in. by 4⅜in. by 2 13-16th inches, or 110¾ cube inches. This size would not be too large or heavy for a bricklayer to handle, and would be such that two brick breadths should, with the mortar joint, equal one length and three thicknesses with the joints the same. 1,000 of such bricks, exclusive of waste, would set exactly 11 yards of 9in. brickwork. The cubic contents of bricks at present made in the vicinity of Manchester range from 94in. to 115in., averaging about 104in. Platt's bricks average 116in.; the samples submitted to the committee by the Master Builders' Association, 140in.; and Hutchinson's, 115in.

Want of attention, besides causing irregularity in size, is also the cause of non-uniformity of material. More careful sorting out of stones, &c., more careful casting and tempering, are necessary to improvement in this respect. With regard to density, while it is desirable that appreciable hollows should not exist in the texture of a good brick, still the materials should not be so compressed as entirely to exclude air, thereby rendering its proper burning difficult and making it heavy in proportion to its cubical capacity, thus becoming expensive in carriage and the cause of outlay where structures require the support of iron beams, or for arching. The committee found the bricks of the Builders' Association compare well in this respect; the weight of a cube foot being 109¾lb. Platt's bricks weighed 123 1-3lb., and Hutchinson's, 120lb.

Tables Nos. 2, 3, and 4, above, show the relative values of different bricks with regard to their power of absorbing and retaining water. Of course the brick which imbibes the least moisture, and that the most slowly, and which parts with it most rapidly, is the most desirable, not only on account of non-penetration of rain, but also for its comparative immunity from injury by frost. From the tables it will be seen that the position of the different sorts as to quantity absorbed in a quarter of an hour, two hours and a half, and fourteen hours was almost uniformly thus:—1st, Hutchinson's (absorbing least water); 2nd and 3rd, hard bricks from Hulme and Bradford; 4th, Platt's; 5th, Collyhurst; and 6th, Builders' Association. In testing the facility of drying, the bricks, after being saturated, were left at a natural temperature. In the first four hours and a half Platt's and the Collyhurst bricks lost only about half of what the others had done. In four days all were nearly equal, and after that the Builders' Association bricks and Platt's surpassed the rest.

The present system of burning common bricks by so-called "close fires," where the bricks are interspersed with layers of fuel, is very objectionable and wasteful, beside causing distortion and inequality of colour. Platt's and Hoffmann's systems are spoken of as the best, but the expense consequent on the adoption of either is stated to be beyond the means of most brickmakers.

The conclusions arrived at as the results of the experiments are:—

That bricks of good quality should be of a uniform size (say 9in. by 4 3-8in. by 2 13-16in.), and should weigh at the rate of about 110lb. per cube foot, or about 7lb. each. They should be rectangular, with true faces, and only the sides and ends need be smooth; the arrises should be sharp and straight. No print sinking on either face. They should not absorb, when saturated, above 20 per cent. of their bulk of water, and should absorb it reluctantly, and part with it with facility at ordinary temperatures. They should be uniformly burned, and have a metallic clang when struck together. They should be tough and "pasty" in texture, and not granular, so as to require repeated blows to break them rather than one single hard blow. Superiority in this respect will cause the bricks to retain their entirety and sharpness of their arrises in carting and handling.

Hand-made bricks, as at present made, cannot be relied upon for complying with the above requirements. With regard to machine-made bricks, Platt's process does not appear to the committee to be practicable in the neighbourhood of Manchester for the production of common bricks. The bricks submitted by the Builders' Association comply with the majority of the qualifications, but should be made smaller; and their granular texture, as well as the friability of the arrises, point to the necessity of some improvement in the tempering of the clay. The bricks made by Hutchinson's process seemed to the committee the best. They were, however, as stated, somewhat heavy, and the process requires some improvement to secure greater rectangularity and uniformity of burning.

GOSSIP FROM GLASGOW.

(From our Correspondent.)

WHATEVER may be the value of the Lord Clyde statue as an expression of British art, the results otherwise cannot fail to be satisfactory to the subscribers. The amount contributed was, with its interest, £2,350 0s 3d.; and after £1,200 were paid for the figure, £398 7s. 2d. for the foundation and pedestal, and some indefinite sum for petty expenses, there was left a balance of £656 16s. 10d. Of this £94 10s. were presented to the secretaries, city architect, and treasurer's clerk; 5s. per pound was returned to the subscribers, and the remainder was given to the Royal Infirmary.

Speaking of sculpture, I may mention that our fellow citizen, Mr. Ewing, has been honoured by the Prince of Wales with a sitting for a bust.

At the annual meeting of the directors of the Andersonian University our eminent local architect, Mr. Rochead, was elected the trustee representative of art.

On the 17th inst., at Jamestown, in the Vale of Leven, there was laid, with full Masonic honours, the foundation stone of a small worship house in connection with the Kirk of Scotland. The style is Gothic, and the building is divided into nave and aisles. Over the entrance is a spire rising 130ft. from the ground level. The building measures 60ft. by 48ft. within, has a gallery on each side, and one in front of the pulpit, and is seated for 900 persons. Three windows behind the pulpit are to be filled with stained glass, the gift of gentlemen in the district. The artificial lighting will be by a "sun-light," with seventy

burners, and the heating by hot water pipes. The estimated cost is £2,500, of which Mr. Orr Ewing, the Lord-Dean-of-Guild of Glasgow, has contributed one half, and Mr. Smollett, of Bonhill, a relative of the poet and novelist, £250. The architects are Messrs. Clarke and Bell, of Glasgow.

The foundation stone of a mission church, in memory of the Rev. Dr. Robertson, of Glasgow Cathedral, was laid on the 15th inst., by his successor, the Rev. Mr. Burns. This building is also in the Gothic style. It is seated for 600 worshippers—500 in the area, and 100 in the gallery. The cost of the building is £1,800, and of the site £1,100. Of this amount about £1,600 have been contributed by the cathedral congregation and by friends of Dr. Robertson. The architect is Mr. Barclay, of Glasgow, a gentleman who has in Gothic architecture shown considerable fertility of invention, although some of his detail is somewhat crude and immature. However, freshness is as welcome as it is rare; refinement in detail will be certain when judgment is appealed to by experience.

Certain of the Glasgow architects, having failed to obtain a special charter, have been licensed by the Board of Trade as a limited liability company under the designation of "The Glasgow Institute of Architects." Some new architectural society, if the profession is to be really represented, has become a necessity, for in the present many of the leading men, such as Rochead and Burne, are conspicuous only by their absence. The objects of the newly licensed company are:—1. The advancement of the art and science of architecture. 2. The consideration and discussion of all subjects and questions connected, directly or indirectly, with the profession of architects, and the concentrated expression of opinion upon the same. 3. The elevation of the attainments, the promotion of the efficiency, and the protection of the interests of the architects of Glasgow. 4. The establishment of a uniform rate of charge by the members for professional business, in cases where no special agreement as to remuneration is made by the parties. 5. The doing all such other things as are incidental or conducive to the attainment of the above objects. And the qualifications of members are:—1. Persons who have served for six years at least as apprentices or assistants with members of the institute, or with persons eligible to become such. 2. Members of other architectural institutes, associations, or societies. As regards the *objects* of the company, every one of them have been at least *professed* by the existing "society," and, as regards the *rules*, the one is admirably adapted to defeat the purpose of the other. In the first place, there is a door that can be passed by only a minimum of six years' study, and in the second, there is a door standing wide open to admit such as may be mere members of other institutes and societies. One "object" of the company might have been to weed the "profession" of all who had not served a regular apprenticeship. With such a rule as rule 2 the architectural profession is in Glasgow as it was.

On Thursday, the 8th, Glasgow was almost literally in "full feather" on the occasion of the Prince and Princess of Wales's visit for the purpose of laying the foundation stone of the new University buildings. There were feathers (Prince of Wales's) everywhere, and in almost every conceivable material. Triumphal arches, flags, banners, Danish crosses, and evergreens were abundant. Architecture was hung with "decorations," and smothered by upholstery. The street decorations were lavish in the extreme. The Prince was presented with the freedom of the city, and for that purpose, he, accompanied by the Princess, was led from Stirling-square (its poverty half hidden by festoons of green leaves and folds of red calico) up back stairs, and through dark, dingy, low-crowned, and irregular passages, into that really dainty place to set before a prince, the City Hall. This *monstre* box, which had defied the genius alike of such a master in colour as D. R. Hay, and of such an adept in form as Alexander Thomson, had just before the royal visit undergone a mild course of white lead, turpentine, ochre, and stencil plate, and this, with a copious draping of the inevitable scarlet cloth, in some degree fitted it for "the expectancy and rose of the fair state." Glasgow must, ere long, have a city hall worthy of the "second city of the empire"—a building dignified without, elegant within, and in a central situation. Of late, the *utile*, rather than the *dulce*, has been receiving attention. The very poorest dwellings have been supplied with water exhaustless in quantity and unrivalled in quality. Way has been made for pure air and the light of day, and now, with plans and estimates at hand, the disposal of the town sewage is being considered. The route of the procession was four miles in length, and of course at intervals there were "grand stands." Notwithstanding the great number of these temporary erections there was not a single accident.*

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE Institute's session for 1868-69 is about to commence. The ordinary meetings, which begin at eight o'clock, will be held on the following Monday evenings:—1868.—November 2, 16, 30; December 14. 1869.—January 4, 18; February 1, 15; March 1 (special general meeting of members only, for the award of medals and prizes), 15; April 5, 19; May 3 (the annual general meeting of members only), 24; June 7, 21. The ordinary meetings of council take place at seven o'clock on the Monday evenings appointed for general meetings. The council also meets before every special meeting.

The volunteer architectural examinations are held in the second and third weeks in May. Applications for examination and all preliminary work must be delivered on or before March 10, 1869. Copies of revised regulations (which will apply only to 1869) together with course of examination, list of books recommended, copy of questions used in the last examination, list of medals and prizes for 1869, regulations for the Pugin travelling studentship, &c., may be had on application to the Assistant Secretary at the Institute, price 2s. or 26 postage stamps. All drawings and essays sent in for the prizes offered by the Institute must be delivered on or before January 31, 1869. The election of candidates for the Pugin travelling studentship will take place on February 15; last day of application, January 31, 1869. The meetings of the district surveyors' board of examiners are held on the last Friday in the months of January, April, July, and October, to examine persons desirous of obtaining certificates of competency to perform the duties of district surveyors. The sessional papers of the Institute can be procured by the public and by members at the rooms of the Institute, 9, Conduit-street, at the following prices, viz.:—1862-63, non-members, £1 1s.; members (one extra copy), 10s. 6d.—1863-64, 1864-65, 1865-66, 1866-67, and 1867-68, non-members 15s., members 7s. 6d. Copies of transactions of former years, viz, from 1853 to 1862, can also be had on application to the Assistant Secretary. The *conversazione* will probably be held towards the end of June or beginning of July.

The library is open to members from ten to five daily (on Saturdays from ten till two), between October 18 and August 30 (excepting the Easter and Christmas weeks), and on the evenings of Monday, Thursday, and Friday during the session, from seven to ten.

John P. Seddon, Honorary Secretary.
Charles L. Eastlake, Assistant Secretary.

GLASGOW ARCHITECTURAL SOCIETY.

THE annual general meeting of this society was held on Monday evening, J. Honeyman, jun., Esq., the President, in the chair. The annual report, which was read, was adopted, and the following gentlemen were elected office-bearers in the society for the ensuing year:—President, Campbell Douglas, Esq.; Vice-Presidents, Angus Kennedy, Esq., James Steel, Esq.; Hon. Secretary, William M'Lean, Esq.; Hon. Treasurer, James Howatt, Esq. Mr. Campbell Douglas, the newly-elected President, delivered his inaugural address. After congratulating the society on its present satisfactory condition, as evidenced by the report, he proceeded to review its progress under the direction and influence of its previous presidents, especially eulogising the conduct of Mr. Alexander Thomson, who, he said, was one of the few existing architects who stamped his individuality on his work, and from whose studio there never issued a design which did not bear the mark of great study and the evidence of considerable genius. He stated that when the letter of the committee reached him, in a distant part of Scotland, proposing to nominate him for the presidency, he at once wrote, advising that the society should again select Mr. Thomson. He wished to decline for himself the honour, but, since it had been pressed upon him, he would do all in his power for the advancement of the object common to them all.

He would, therefore, say to all architects that unless their work was studied patiently, earnestly, and with a sincere love for the work, it would never be satisfactory, or command the admiring attention of any well-informed critic. It was a great misfortune both for the man and the community—so far as art was concerned—when he had more to do than he could personally overtake. There were many people—perhaps the great majority—who would think such a statement nonsense. If their supreme object were to get a commission on the value of the buildings for which they were architects, then the more extensively they were employed the better; but he would comfort all true lovers of pure and noble art by telling them that if they could support life, and honestly pay their way, and have a mind refined by culture, and had made friends for themselves with the nobility of the past, in the world of letters and the world of art, and could thereby appreciate all that was beautiful, whether past or present, they might be content to labour in comparative obscurity, and could afford to let the patronage of the ignoble go past unsighed for. Again, if an architect's work were not studied with due regard to mass and detail, those who could understand it would very soon discover that not only had the work lost all individuality—which was the very essence of art—and, chameleon-like, had merely assumed the colour of the day that might be shining in the darkness of his place of business; but it would be found to be either full of crudities, or of such repetitions constantly cropping out in that and other buildings, as would destroy its art character. It would be unpardonable presumption in him to venture on anything like direct criticism on some of the later buildings of living architects, but he had very decided opinions on the merits and demerits of many of them; and he would gladly point out their defects, as they appeared to him, but for two reasons—first, all kinds of artists were, rightly or wrongly, supposed to be swayed by such unworthy jealousy of each other that it would be scarcely possible to get one's criticism considered fair and unbiassed; and, secondly, even supposing the criticism just, it would stir up feelings of ill-will, and be a fruitful source of discord. He desired, however, earnestly to insist that good architecture was just like good painting, good sculpture, good music; it was seldom that what was the best struck them at the first as being so. It ought to gain upon them, as they had opportunities of knowing it, like the qualities of a desirable friend, which were seldom apparent to a bowing acquaintance. If there were anything good at all in a building, it would generally be a reflex of the mind of its designer; if not, it was like an image in a twisted mirror, untrue and bad. There ought not to be any thrusting obtrusiveness, but a very modesty that would only be discovered by its blushes. There must be dignity and worthiness, so that a little accidental forgetfulness could be passed over in the general repose; there should be nothing superficial or shallow; let it be broad and deep, where they could see the lights and shadows of life, that invested all existence with interest; it must be considerate, and not offend its poor neighbours by its goodly apparel; it might be all that is admirable, and yet not proud; and it must be elegant and refined, though not necessarily costly. Now, if the buildings sinned in this way, what should we say of those who originated them? Either they were ignorant men, or they yielded to the temptation of making much money by doing bad work, as there were more people who like bad architecture than good. These men should leave off preaching on stone; their sermons were so bad. There were plenty of respectable trades where they might realise ten or twenty times their present income, and in pursuing which they would not corrupt the public taste, and dishearten real artists who are working carefully and perhaps unheeded. In the grand new buildings of their University, whose foundation stone was laid the other day by the Prince and Princess of Wales amidst the enthusiasm of the people, he would hail with joy the possible establishment of a Chair of Architecture. He could conceive nothing that would be of greater use to art, or more likely to make study a branch of liberal education. Within late years the number of

* To be concluded in our next number.

professorships has been largely increased; and under the impulse of its west-end life, in purer air and healthier influences, it might not be Utopian to hope that this want might be supplied. Thanking them for giving him the opportunity of so addressing them, and assuring them of his deep interest in all that concerned their professional well-being, he would say there was plenty of work before them all, in city improvements and sanitary improvements, which were but the fulfilling of the second great commandment, with all of which the artistic element, for which he had been pleading that evening, might go hand in hand. And so, all doing the duties that lie before them diligently, humbly, and thoroughly, they would in every-day life be so far preparing themselves to go up to the great city built without hands, whose foundations were all precious stones, and her gates pearls.

ST. JOHN'S CHURCH, TORQUAY.

THE illustration of this church appeared in the last number of the Building News. The church is being built by degrees to take the place of a poor modern building of nondescript design. The design is by Mr. G. E. Street. The first portion built was the chancel, with aisles and sacristies. This is built of Ham Hill stone and local limestone, and is vaulted throughout with flying buttresses. The east window is by Messrs. Harris and Marshall, from the design of Mr. E. B. Jones. The reredos has a sculpture of the crucifixion. The north aisle of the nave, and the north clerestory, are also completed. The old building still, therefore, opens into the new chancel at the east end, and into the new aisle at the north. It is, however, we believe, hoped ere long to carry the work on to completion. There will be a tower at the south-west angle of the church.

THE JUNIOR CARLTON CLUB.

THE Junior Carlton Clubhouse, lately built in Pall-mall, near the Army and Navy Club, has another frontage in St. James's-square. It was designed by Mr. David Brandon, the architect, and built under his superintendence, at a cost of £40,000, by Messrs. Lucas Brothers. Its interior is conveniently arranged. On the ground floor is an entrance-hall, 27ft. by 23ft. 6in.; a reception-room, 29ft. 6in. by 20ft. 6in.; a morning-room, 89ft. by 27ft.; a smoking-room, 28ft. by 29ft. 6in.; and a principal staircase, 30ft. by 23ft. There is a second staircase and attendants' rooms, with an entrance in St. James's-square for members who have bedrooms. On the first floor is a members' coffee-room, 90ft. by 27ft., divided by a plate-glass screen from a strangers' coffee-room, 27ft. by 27ft.; a house dining room, 28ft. by 20ft. 6in.; and a library, 40ft. by 29ft. 6in. There is another serving-room on this floor. The height of these stories is 20ft., except where the mezzanine occurs on the north side. On the second floor are two billiard-rooms—one 27ft. 6in. by 27ft., the other 29ft. by 21ft.—the secretary's offices and bedroom, and a second smoking-room for visitors. The remainder of this floor and the floor above are occupied by eighteen bedrooms, which will be let to members of the club. The topmost story provides accommodation for about fifty male and female servants. Under the ground floor and above the basement a mezzanine story is formed, having six dressing and bath rooms, with separate corridor and staircase; the steward's office, still-room, housekeeper's room, and stores. In the basement are the kitchen, 40ft. by 29ft., and the scullery, 25ft. by 17ft., which are continued up to the ground floor, giving a height of 19ft.; a servants' hall, butler's pantry, plate-closet, kitchen, clerk's office, cook's room, kitchen-maid's room, larders, steward's room, wine-cellar, and dispensing-cellar. Outside, in the vaults under the pavement in St. James's-square, are cellars and larders for different stores.

NEW DIRECT ROUTE FROM ISLINGTON TO THE CITY.

A PLAN long since projected for the opening out of a direct route from Essex-road, Islington, to Moorgate-street, is at length on the point of being realised. The northern section of the proposed new thoroughfare is a fine wide street called Packington-street, extending across what were once the Britannia-fields from Essex-road to the Regent's Canal. Crossing the canal bridge (which is to be widened), the route proceeds along Shepherdess-walk to the "Eagle Tavern," City-road, and St. Luke's workhouse, which stand at opposite corners. Here the barrier which has extended across the thoroughfare for so many years will be removed, and the boundary wall of the workhouse grounds will be set back a considerable distance, making Shepherdess-walk of one width throughout. Crossing the City-road, and proceeding citywards, the route will be continued along Bath-street, the southern end of which has been widened by setting back the wall of St. Luke's madhouse to a line ranging with Alleyn's almshouses. Crossing Old-street the whole length of Bunhill-row will be traversed, and, Chiswell-street being reached, a short cut through Type-street and Moor lane will bring the new route to a termination opposite to the Moorgate street station of the Metropolitan Railway. The project has often before been mooted, but business is evidently meant this time. The Bath-street section was opened yesterday (Thursday) with some little ceremony by the vestries of the several parishes interested. Mr. Vulliamy, the arbitrator appointed by the Metropolitan Board of Works, and Mr. Clutton, the arbitrator appointed by the parish of St. Luke, have agreed on Mr. John Shaw, of Christ's Hospital, as arbitrator between them in the matter of determining the value of the strip of land taken from St. Luke's workhouse for widening Shepherdess-walk. The cost of widening Shepherdess-walk will be defrayed by the Metropolitan Board. This and the Bath-street section of the route have hitherto presented the greatest obstacles to the advancement of the project. These surmounted, a great local want will be met.

GROTESQUES.

THE grotesque sketches which are published in this week's number aim chiefly at economy of work. In the majority of the designs the bulk of the material is left square, form and expression being produced by scooping, sinking, and chamfering. No. 1 is an ornamental stop to a chamfered angle. The grotesque figure in this should project sufficiently to act as a gargoyle. This is intended to be worked in stone. Nos. 2, 3, 4, 5, and 7 are for timber brackets or bracket endings, and in these the *square manner* is more fully shown. No. 6 is a gargoyle or angle figure. Nos. 8 and 9 are intended for iron standard heads. One thing, which is partly illustrated by the sketches, I would like to call attention to, and that is the variety of ways in which "eyes" may be simply and economically represented conventionally. In this group, I think, there are seven methods shown, and these only touch upon and by no means exhaust the number of treatments possible of the subject. The eyes, and, indeed, all the other features, are susceptible of an infinite variety of manipulative treatments, which would enhance the interest of the subjects in a proportionable degree to the variety and success of the handling. The Building News for April 3 of the present year contained a sheet of grotesques, and in the article which accompanied it a few leading principles were mentioned by which the designer of grotesques should be guided.

J. M. S.

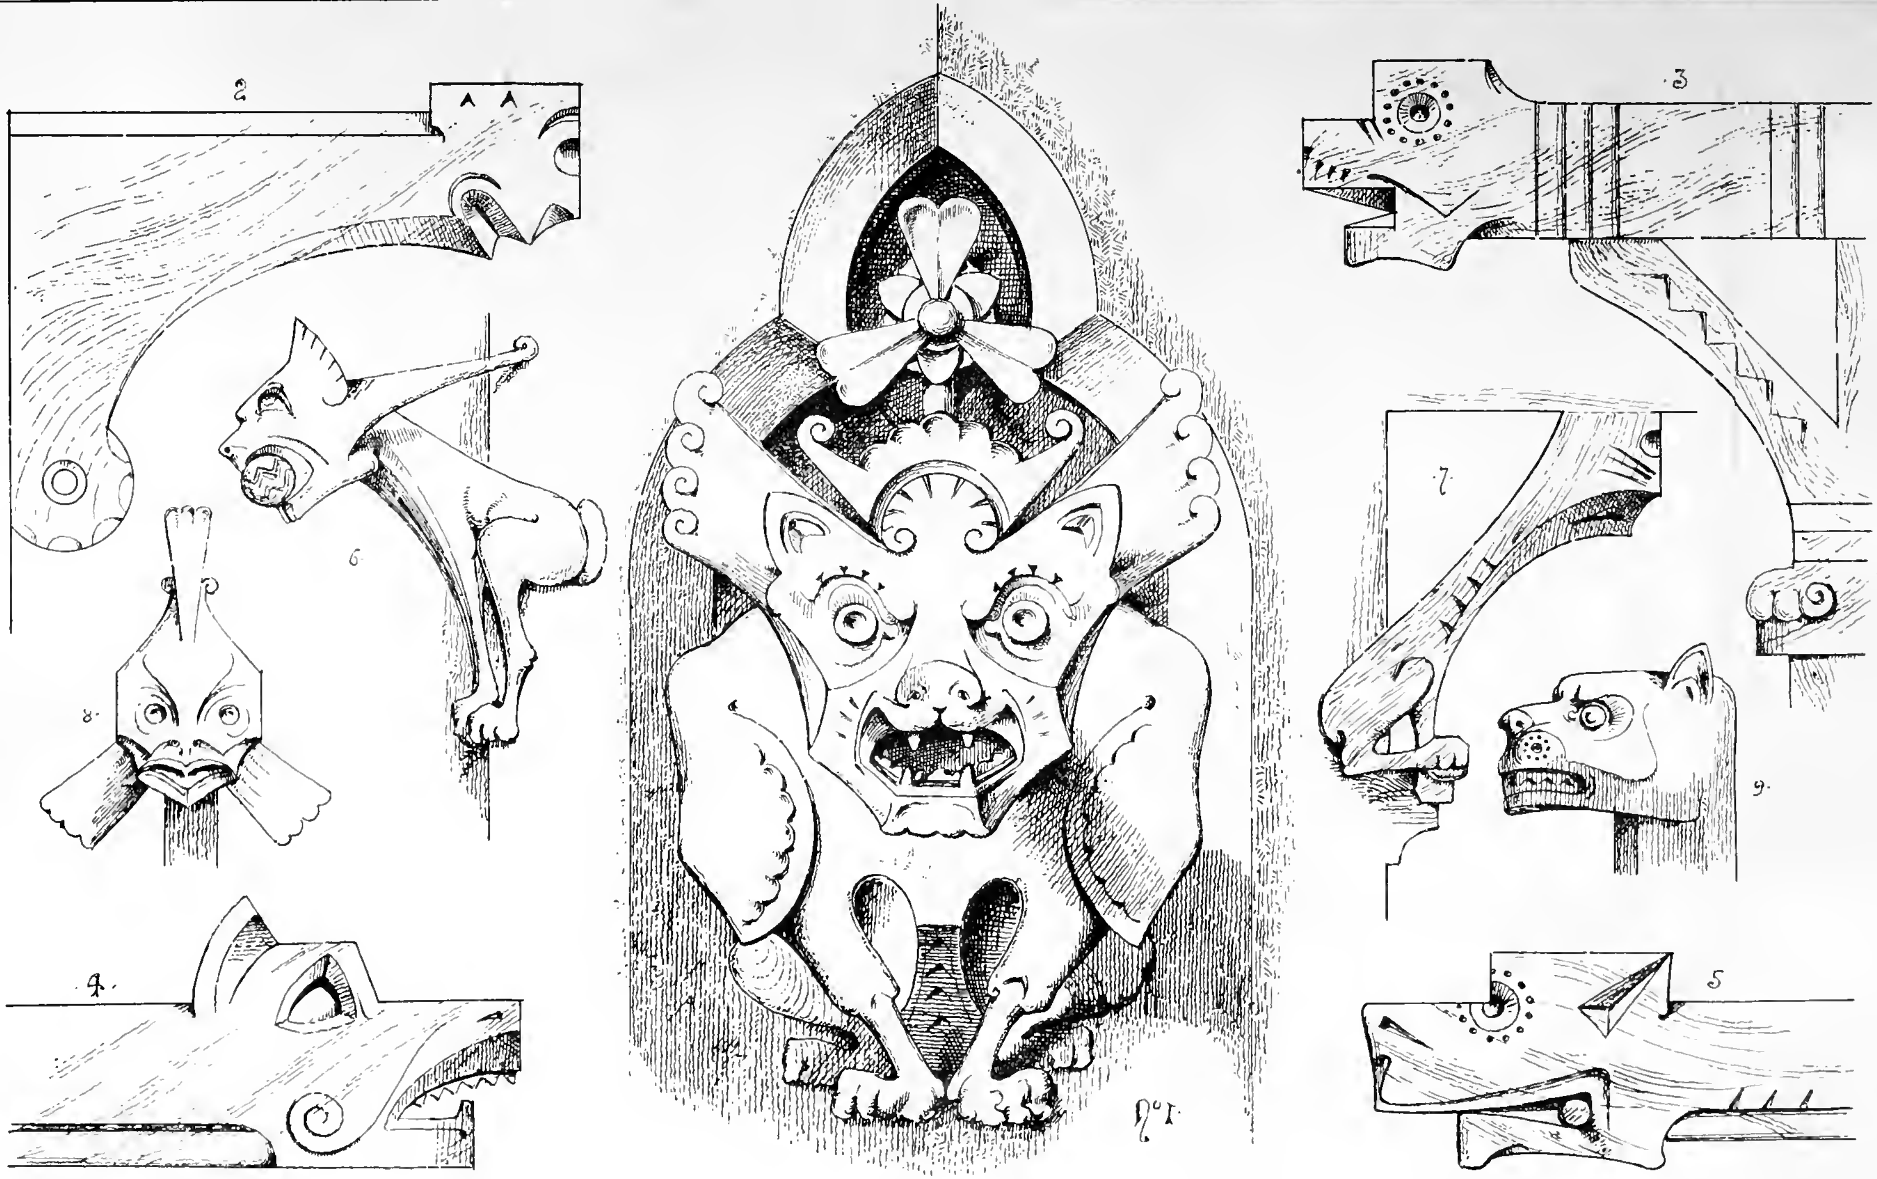
METROPOLITAN DISTRICT RAILWAY.

THE section of this line between Westminster Bridge and Gloucester-road, Brompton, is progressing satisfactorily, and will probably be opened by March next. In another year from then it is expected to be advanced under the whole length of the Thames Embankment to Bridge-street, Blackfriars. Three or four years, however, will probably elapse before the "inner circle" recommended by Lord Granville's committee can be completed by carrying the line on to Tower-hill to join the eastern extension of the Metropolitan line from Moorgate-street. When the improvements in Palace-yard were decided upon by Her Majesty's Commissioners of Works, Lord John Manners insisted upon the company at once making that portion of the line lying between Bridge-street and the Westminster Palace Hotel. This portion has been finished since February last year. Now, however, the line is being extended on the one hand through Westminster to Brompton, and on the other under the Embankment to Blackfriars. There will be a station at the foot of the Clock Tower for the accommodation of M.P.'s. Between the Broad Sanctuary and the Broadway there will be a station. From the Broadway the line passes through Emmanuel Ground to the Victoria Station, opposite to which will be another station. Passing beneath Eccleston-place, the next station reached is Sloane-square. Leaving Sloane-square, the line continues in a north-westerly direction through Chelsea to the Brompton-road, which is crossed a few yards eastward of the "Admiral Keppel." This would be an admirable point for a station, being so near to the South Kensington Museum; but the station is not to be here, but further on, in the Old Brompton-road, at the corner of Onslow-crescent. From this station the line will continue until Gloucester-road is reached. The portion of the line between Paddington and Gloucester-road was, as we have already announced, opened on the 1st inst. Wherever practicable, the line is carried through open cuttings. Throughout the whole course of the line the contractors found a bed of gravel. A vast number of houses of a wretchedly squalid and dilapidated character, in the neighbourhood of Tothill-street, have been demolished for the purposes of the line. The company intends devoting some of its surplus lands, however, to the erection of workmen's dwellings.

THE NEW FINSBURY PARK.

THE inhabitants of North London have received with considerable dissatisfaction the announcement of the Metropolitan Board of Works, offering for sale for building purposes 20 acres out of only 131 acres acquired for the formation of the park. The act of Parliament passed in 1857 gave to the Board power to acquire 250 acres, and granted permission for 20 acres to be disposed of. The Board have only acquired 131 acres, and yet wish to sell 20 acres of land, situate on the best frontage of the park. On Monday evening a very large meeting, under the presidency of Mr. Torrens, M.P., was held at Myddelton Hall, Islington, to take public action in the matter. A resolution was moved by the Rev. W. B. Mackenzie, "That this meeting views with great surprise and regret the course contemplated by the Metropolitan Board of Works to dispose of a large portion of the ground already purchased, and positively required, for the purposes of the Finsbury Park; and feels certain that if the intention of the Board be carried out, the object of the legislature will be frustrated, a great injustice will be inflicted upon the inhabitants of the borough, and the usefulness and beauty of the park, as a place of public resort, will be materially and permanently injured." Mr. Alfred Walker seconded the resolution, which was supported by Mr. Alderman Lusk, who was received with warm applause. In the course of his remarks Mr. Lusk said that, as the London of to-day would be a very different place from what it is if it were not for the parks preserved to it in bygone times, so the London of the future must be provided for in its outskirts; for as its vast population increased there were increased necessities for abundance of fresh air and such breathing-places as these parks afforded. He declared that it was a mortifying thing that the 250 acres which the House of Commons gave to Finsbury should, by the action of the metropolitan local representatives and the Board of Works, be cut down to 131 acres; but it was unbearable that this reduced plot should be curtailed by having its frontages sold for building sites. It was shown that the west-end parks amounted to 831 acres, that Regent's Park had 403 acres, Victoria Park 280, Battersea 230, Greenwich 170, and it was maintained that at the least Finsbury was entitled to the 131 acres of which the present park consists. The resolution was adopted by acclamation, and other steps taken to press upon the Metropolitan Board of Works the injustice of curtailing the park. The meeting authorised other steps to be taken failing the efficacy of this memorial, and the proceedings terminated with cordial thanks to the chairman and his colleague for attending.

A movement has been set on foot in Winchester for improving the dwellings of the poor. It is proposed to take the building lately occupied as the county hospital, and, after effecting certain alterations to let it out in tenements. A company on the limited liability principle is to undertake the matter.



Grotesques by J. Moyr Smith

The Junior Carlton Club, Pall Mall.—Mr DAVID BRANDON, ARCHITECT.

THE RESTORATION OF ORGANS.

WHEN I began these notes on the present deplorable condition of the organs in St. Paul's and Westminster Abbey I certainly had no idea that the subject, important as it is, would have created so much interest as it has done, and which is proved by the letters of correspondents about it; still less could I have thought we should have to encounter subjects so profound as are indicated in "H. H. S.'s" letter of last week. My simple object was, and is, to show, as far as I can, the mistakes that were made, both musically and architecturally, by those who so hastily and unthinkingly advised and carried out the alterations both in the positions and arrangements of the organs in the two cathedrals. I do not know which is the best organ in London, but it will be acknowledged readily that that in the Temple Church, now so lost, is a particularly fine one, and that there are pipes in it singularly sweet and beautiful not to be heard elsewhere. The Westminster organ, good as it may be, cannot be considered quite worthy of the place it occupies, while the organ at St. Paul's, when it stood in its old place, was so out of repair and order that I have heard Mr. Goss more than once declare that he could hardly play on it. But in the face of all this I thought that this organ, however played, *always* sounded more musically, clearly, and deeper than all others elsewhere; and it was impossible to avoid the conclusion that it was all, or in great measure, owing to the *building* it was in and the place in that building which it occupied. This consideration leads naturally and obviously to a few thoughts on the acoustical properties of buildings, and will show to the simplest what infinite advantages there are in large and solid buildings, as far as their musical properties are concerned; and will, at the same time, be a reply to some of the objections made to the views advanced even by so eminent a person as M. Thalberg.

It is a very difficult, if not impossible, thing, to explain in words, however carefully selected, a *sound* of any kind, most of all a musical sound. It is not an *echo* in the usual and common meaning of that word. An echo is a *reflected* sound merely; but what I referred to as taking place, and as heard in St. Paul's, was what is sometimes called, when applied to rooms, "resonance;" but even that term does not explain it clearly, and unfortunately there is no single word in the language that does so. What really takes place is this. In a common church—as in St. Sepulchre's, close to St. Paul's, which is an ordinary parish church, closely pewed, and with heavy galleries, and with floor covered with matting, and walls thickly coated with paint, to say nothing of curtains and lined pews—an organ pipe, or chord of pipes, when filled with sound by the air passing through them, of course fills the whole church with sound during the whole time the air is thus passing and while the valve or valves are open, but the moment they are closed the sound ceases and comes to a dead stop, like the sound from the blow of a hammer on a table; there is no *echo*, or resonance, or sounding air, even when the full organ is at work in a "Bach" fugue or Handel chorus; there is not the slightest trembling or sound in the air after the final note or chord has ceased. The whole music is over the moment the fingers of the performer leave the keys. Not so in St. Paul's or even Westminster. An organ pipe, when the organ was in its old place, if sounding but for one second, the key being simply struck with the finger, of course ceased to sound in the pipe at the end of the second, or instantly the finger was raised from the key; but the sound did not end here as in a common church, for the sound from this single pipe, though it was but a small one, filled the whole cathedral—*i.e.*, the air held the sound for a longer or shorter time—and thus was the note held on for some seconds, the sound trembling in the air. Indeed, simply a *cathedral effect*, to be heard nowhere else, and peculiar to a cathedral, and especially characteristic of one. What thus happened on the sounding of a single pipe was, of course, increased, and deepened, and intensified with a chord of pipes and a full organ; and I contend that nothing could possibly surpass the magnificence of it. Not only was it a thing in itself worth all preservation, but it added, as I before said, to the thought of the composer that which he could never have written, or, indeed, even have imagined; for there are things in nature beyond all power of mere human thought and contrivance, and this is one of them. If this cathedral of St. Paul be worth the money and time and skill it cost as a mere empty work of art and architecture—and most people will agree that it is—then I contend it is all a hundredfold increased when it enshrines so wonderful a combination of musical and mechanical invention and skill as an organ; and yet more so when such instrument is found capable of realising and making evident to the ear the finest and most glorious thoughts of those who have been gifted with the rare and precious faculty of musical composition. In this way, therefore, it was that the building and organ, and the position of the organ in it, helped the composer's work; and it is difficult to find words to describe the dulness of those who did not perceive it, and who so blindly and thoughtlessly marred it all, or, as in Westminster Abbey, destroyed it altogether. It is here to be observed that in St. Paul's the whole effect was produced solely by the building *as a part of the organ*, and from the unequalled position of the organ in it, while in Westminster—from causes which would take us from the present subject to try to explain—the whole of the work was done through the consummate skill of the organist and the mere position of the organ in the centre of the screen. Surely this important subject is worth a little consideration at the hands of those who have done all this mischief, and surely, too, no mere question of expense in such places as St. Paul's and Westminster should be allowed to stand in the way of the putting back in their time-honoured and proper places those organs.

I do not know how I can reply in detail to the objections that have appeared to this proposed "restoration" of cathedral organs. To do so would take up some considerable time and space, but surely it is hardly necessary, for what can well be said to anyone who affirms that an organ is "subsidiary to sound," except to own that it is. Or what can be said to one who tells us that the "piers" of St. Paul's are "not massive," or that the organ is not now "buried," when the top of it had to be cut off to get it under the arch? Why, to have got this organ fairly under the arch where it now is, it must have stood on the floor of the church, thus to give it proper head room! Be it recollected, too, that it is not only the position of the instrument close under the arch, but its absence from its most suitable and most lucky place near the dome, and with a clear air space above it. What, again, does it matter what Wren thought about it? If he had not the fine sense to give way cheerfully to Bernard Smyth, who really understood it all—and to him, therefore, be the credit of the good work—there were those who compelled him, and such ought there to be nowadays. Wren was a wilful man doubtless, and loved his cathedral, as I do, but he would have loved it more if he had patiently listened to the sublime effects Bernard Smyth's genius, equal to his own in its way, added to it.

I must add, as it is a curious subject, that on referring to the full score of the "Creation," I find, as was to be expected, that "H. H. S." is totally in error in supposing that Haydn had added a violin movement expressing the effect of a sustained sound *after* the full band or organ had ceased. "The wonders of His work" are the last words of this magnificent anthem, and the final word "work" occupies half a bar's length, while the instrumental accompaniment to it occupies but a quarter of a bar's length or one-half of it, so that the vocal part runs into the instrumental "rest," whether that instrumental part—and this is the present question—be a full band, consisting of many instruments, as trumpets and violins, or simply an organ. The "rests" are the same, and it was during these rests or pauses that the beautiful effect I spoke of told so finely. Nothing can be simpler than it is, but it takes a good deal of skill and vigour to do it well, and certainly half the sublimity of it goes and is lost in a place like Exeter Hall, where all sound ceases with the instruments, and where there is no resonance or *air sound*, as there always is more or less in a cathedral, but nowhere so finely as in St. Paul's. What is, therefore, to be said to M. Thalberg? Surely he would not prefer Exeter Hall to St. Paul's!

C. B. A.

MEDIÆVAL DOOR FASTENINGS.

(FROM OUR SPECIAL CORRESPONDENT.)

BIRMINGHAM.

THE Loan Collection of Mediæval Metalwork from South Kensington, now on view at the Free Library in this town, is naturally exciting a good deal of attention among the manufacturers in the great "toy-shop of Europe." In it is displayed the progress of industrial art through many centuries and in many climes. Enamelling, chasing, embossing, carving, casting, moulding, and every other process of artistic metalwork is here set forth to perfection. In many instances the modern products of Birmingham compare not unfavourably with the Flemish or Italian workmanship of the dark ages, but in some departments, so far as regards fine art, the old time is far above the new. Perhaps this is nowhere more conspicuous than in connection with door fastenings, locks, hinges, knockers, and bolts, articles in which nowadays we are too apt to sacrifice ornament for the sake of utility, instead of following Mr. Ruskin's advice, and combining both virtues in a happy medium.

Among the locks of mediæval workmanship which most attracted my attention were the following:—Specimens of eighteenth century (French) lock: front of chiselled iron, with *applique* floriated scrolls, very elaborately entwined. On either side of the keyhole escutcheon is a dolphin, looking menacingly, as if to scare the possible intruder and protect the portal from violence or fraud. *Serrure de Tabernacle*, sixteenth century (French), is a delicately chased specimen of wrought iron; the centre or hasp is ornamented with figures of the Eternal Father, the Virgin, and St. John, under a richly wrought Gothic canopy. It is noticeable that the Gothic tracery on the face of this lock is built up of pierced plates riveted together, and giving the effect of moulded tracery. A Flemish lock, seventeenth century, has an architectural façade for the front plate, a design which is perhaps more curious than useful. Keys of eighteenth century German work are very elaborate. A chamberlain's key of office, for example, in gilt bronze, had inserted in the bow a lion rampant, surmounted by an electoral crown. Another bore the chaste device of the *fleur de luce*. Twisted stems, floriated scrolls, and interlaced ornamentation present a strange and humiliating contrast to the plain, straight keys of the present day.

Other specimens of door furniture were equally elaborate on the continent during the fifteenth and sixteenth centuries. A bronze cinque-cento Italian door-knocker attracted my attention. It is a pleasing and graceful composition of syrens and *amorini*, or "little Cupids," and is attributed to that worthy descendant of Tubal Cain, Giovanna di Bologna. This grand old artist in metal was one of those immortal workers who sat

down to construct a lock for city gate or cathedral door just as Raphael would sit down to a *Madonna* which should attract the reverent admiration of ages to come. Elihu Burritt, "the learned blacksmith," has somewhere well observed, "The artist mechanic of that age was moved by the same impulse and in the same direction as Raphael. The religious enthusiasm of the time inspired him with the same devotion to his work, and he threw his whole heart, mind, soul, and body into it. If the great Italian painter presented to the world his 'Assumption of the Virgin,' he fixed his eye and heart upward in the wake of the same glory. He, with his steel pencils, chisels, and drills, would do something in the same line. And he did it. His idea was rude and material, but his sentiment was honest and clear; and let no one of this later age of light blame him for his conception."

Whether the artistic genius of mediæval times will ever be displayed in modern door fastenings seems problematical. At present our locks and keys certainly appear in strange contrast by their plain—not to say uncouth—appearance, with similar productions of the dark ages. Instead of being ornaments, they are too often objects of deformity upon our doors, and in mortice locks more especially we seem to carry out Lord Palmerston's well-worn version of the Latin proverb, "Artis est celare artem." An absorption of the countless domiciliary lock-shops of South Staffordshire into a few large and well-organised factories, together with a wholesale application of machinery, would quite revolutionise the trade in respect of art workmanship by relieving the artisans of their drudgery, and rendering them freer to exert their ingenuity in the higher branches of handicraft. This, however, must be a work of time. Meanwhile, we may hope that Longfellow's injunction to art-workmen may resemble in its influence a true poet's echoes :—

> In the elder days of art
> Builders wrought with curious care
> Each minute and unseen part,
> For the gods see everywhere.
> Let us do our work as well,
> Both the unseen and the seen,
> Make the place where gods may dwell
> Beautiful, entire, and clean.

ARCHÆOLOGY.

The scientific investigations among the graves of the ancient Britons, which, at intervals, for three years past, have been carried on by the Rev. Canon Greenwell, of Durham, and other archæologists, upon the Yorkshire Wolds, have been resumed, and are occasioning much interest. Two large barrows have been examined, both of which have proved prolific in remains, and have yielded results of a valuable nature, some of which have hitherto not been previously observed. Barrow No. 1 was 66ft. diameter and 2ft. high, formed of earth and chalk rubble. Three burnt bodies were found, and at the centre of the barrow a grave was dug into the rock N.W. by S.E., being 8ft. 6in. by 4ft. by 3ft. 10in. deep. In the "filling in" of the grave, some teeth and various bones of a disturbed human body, with three pieces of urn and a piece of jet were found—doubtless the remains of a primary interment, disturbed by the digging of the grave for a later burial. At the bottom of the grave was the body of a man lying on his left side, at the south-east side, with head to south east, the body contracted. In front of the head was a fine pierced stone axe hammer, the edge of which was touching the face, the handle having been held in the right hand. The edge had never been intended for cutting, it being carefully squared, more like a modern thin edged hammer. The weapon or implement is a splendid example, has clearly never been in use before it was interred with its owner. Closely adjoining this grave was another, N.E. by S.W., the two being united by an excavated passage 2ft. wide. The second grave was 6ft. by 4ft. 6in., and a few inches shallower. At the north east end was the body of a woman, contracted, the head to north east, the two burials therefore facing each other. The second barrow was 70ft. in diameter, and only 1ft. 6in. in height, of the same formation, and containing similar remains to those above described.

On Tuesday, as the workmen were engaged in excavating the ground for the foundation of the new Temple Hall, they discovered a portion of a gilt door of the fourteenth century, the gilding and the stonework being in excellent preservation. The ancient relics were taken care of, and are now in the possession of the principal foreman of the works.

The Rev. E. Kell has, during the last few weeks, uncovered two rooms and the wall of a third room of the Roman building discovered at Cowes in 1861. The Roman building, the entire of which has now been uncovered, was about 70ft. in length by 13ft. 6in. in breadth, and consisted of five rooms in a line. The two rooms at the west end had tesselated pavements of a common kind, made from tiles. The third, or middle room, had the remains of a fireplace, and from the relics of pottery, bones, oyster shells, bill hook, knife handle, &c., was a kitchen, or eating-room. The fourth room had the relics of two or three querns, by which the corn for the inmates was ground. The fifth room was similar to the third. It exhibited signs of fireplaces, and a considerable quantity of crockery, Samian ware, bones, and shells. The building had been consumed by fire, and a large amount of burnt materials was discovered in this room.

Building Intelligence.

CHURCHES AND CHAPELS.

The opening of a new Catholic Church at Windsor, dedicated to St. Edward, King and Confessor, took place on the 15th inst. with much ceremony. The church, a substantial building of Heath stone, when finished, will hold a congregation of 600; its cost is estimated at £4,000, which will be defrayed by voluntary contributions. Mr. Berkley is the architect.

On Wednesday week Dr. Ullathorne, the Roman Catholic Bishop of Birmingham, laid the foundation stone of a new church at Swinnerton, near Stone. The new church will be built from the designs of Mr. Gilbert Blount, of London, and its cost will exceed £4,000. The style of the church will be that of the transition between Early English and Decorated. It will consist of chancel, with aisle, tribune for the family at the hall, sacristies, porch, and belfry. The erection of the building has been entrusted to Mr. Heveningham, builder, of Wolverhampton.

A new Wesleyan Chapel is commenced at Varteg, near Pontypool, Monmouthshire. It has gallery, vestries, class rooms, stoves, &c., and accommodates nearly 400 persons. Mr. E. A. Lansdowne is the architect, and Mr. Henry Parfitt the builder.

On Saturday last the memorial stone of Christ Church, Windhill, near Bradford, was laid by the Lord Bishop of Ripon. The building, which will cost £4,200, exclusive of spire, is from the designs of Messrs. Andrews, Son, and Pepper, of Bradford. The body of the church is 75ft. long by 56ft. wide, the plan consisting of nave and two side aisles.

On Thursday week a new iron church was opened at New Wandsworth. The interior, with its side arches and clustered columns, its lofty open timbered roof, its stained glass windows, and its plastered walls, presents an appearance as comfortable as that of a brick or stone building. Accommodation is provided for 500 persons, and the entire cost was under £3 per sitting. Messrs. F. Morton and Co., of London and Liverpool, were the contractors.

At a meeting of the Committee of the Carlisle Diocesan Church and Parsonage Building Society, held on Wednesday week, grants in aid of building and restoring churches were made to the following places, all in the county of Cumberland:—Plumbland, Aikton, Blackford, Cotehill, Gatesgill, and Warwick.

BUILDINGS.

On Friday Mr. Edward Nathan, president of the Manchester Jews' Schools, laid the foundation stone of a new school in Derby-street, Cheetham-hill. The building will be erected from the designs of Mr. E. Salomons, architect, by Messrs. Cochran, Parker, and Co. and is intended for the accommodation of 700 children.

At Braughin, Herts, a new school has just been opened. It is built in the Gothic style, with red bricks and white brick dressings; the roof is high pitched and slated. The cost was about £400, the contractor being Mr. T. Ginn, of Puckeridge.

New gas works are to be erected at Maryport, Cumberland, at a cost of £8,000. The plans have been prepared by Mr. Flintoff, C.E., of London.

Mr. Whitaker, surveyor, of Tiverton, has prepared plans for a new public hall over the Higher Market in Queen-street, Exeter. The hall will be 150ft. by 100ft., and will seat from 3,000 to 4,000 persons. The estimated cost is £5,500.

On Monday week the new Turkish Baths were opened at Brighton. The building was illustrated and fully described in the Building News of December 13, 1867.

TO CORRESPONDENTS.

Notice.—Cases for binding the BUILDING NEWS, Vol. XIV., are now ready, price 2s. each.

To Our Readers.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

Received.—M. T. S.—H. and Co.—C. H. and Co.—J. S.—J. M. S—M. D.—G. R and Co.—I. F.—W. B. and Co.—C. S. J.—I. C. S.—I. I. C. and Co.—W. H. C.—I. H.—W. B. R.—C and Co.

J. Roe.—Intercommunication is not meant for "exchange" purposes. Your communication is simply an advertisement, and can only appear as such.

Builder had better consult a lawyer.

Brickbat.—We cannot insert your question, as we cannot read your writing.

Correspondence.

CATHEDRAL ORGANS.

To the Editor of the Building News.

Sir,—Will you allow me to remark that the intention of my letter of October 9 was merely to correct the errors of your correspondent "C. B. A.," and to state the truth? I anxiously look forward for the "enlightening views" of "C. B. A.," and hope that among his suggestions we shall have something fresh.—I am, &c.,

C. S. J.

ORGANS ON SCREENS.

Sir,—Circumstances have prevented my taking earlier notice of the very extraordinary assertion of your correspondent "C. B. A.," that the practice of placing organs on choir or rood-screens has the sanction of "antiquity." I think he is mistaken. The old views by Hollar of the interiors of Lincoln Cathedral and Old St. Paul's (see Dugdale's "Monasticon" for the former, and Dugdale's "St. Paul's" for the latter) distinctly show the screens without the decoration of any organ on them, and in the views of the choirs of both those cathedrals the organ is shown in each as being on the north side of the choir over the stalls. Westminster Abbey organ, too, was formerly in that position, as I have seen it thus represented in a print I once saw of the interior of the Abbey taken some time in the early part of last century. The organist of the Abbey also told me, a few weeks since, that the organ used formerly to stand on the north side of the choir, over the stalls, before its removal to the screen.

There are a few organs abroad on the rood-screen, but they are very few indeed. I believe there is one in a church at Bruges, and I have seen one at Antwerp so placed, in the Church of St. Jacques, but this organ is divided, much like the Westminster Abbey organ, so as to spoil the view from west to east as little as possible. In Spain, too, where there are solid screens and enclosures enough and to spare (which would charm "C. B A."), there are generally two organs of the largest size in the choirs; but they face each other, north and south, and do not stand on the great screens in the centre of the naves of the churches. In Toledo Cathedral there are three monster organs, two in the choir, as usual, facing each other, north and south, and a third large one over the door of the south transept.—I am, &c.,

Western Organ.

London, October 20.

ST. PAUL'S ORGAN.

Sir,—It might have been supposed that the subject upon which "C. B. A." has favoured us with his opinion was of sufficient interest to warrant its discussion in moderate language and upon a basis of ascertained fact. Neither of these desiderata appear to influence your correspondent, whose onslaught on Mr. Penrose and the large organ is manifestly founded on prejudice or deficient information. We are now told that the new organ is thrust up against the wall, close to the roof, where the swell is only heard by the birds outside, and the tone utterly lost. Now I will venture to say that never was there a more reckless statement, or one more removed from truth than this. The swell, so far from being "lost," is one of the most effective known, and the whole

organ is generally acknowledged, in musical circles, to have the grandest effect all over the building, and one unsurpassed by any organ in the kingdom. It is not "close" to the roof, as anyone may see for himself; but I speak from knowledge of the facts when I say that the top of the swell box is 20ft. from it; the swell organ itself 30ft. below, and the great organ 45ft. below it. So much for its being close to the roof; but why "C. B. A.'s" consternation and dismay at seeing an organ placed against a transept wall? Surely he would not have it *away* from the wall, leaving a useless space behind? Are not organs placed against transept and nave walls abroad? Look at those at Notre Dame, Rouen, Cologne, &c, the latter a transept organ, and who but your highly sensitive correspondent would feel dismay at an arrangement which ordinary mortals think the best possible? As to architecture being spoiled, the thing is absurd. Where can an organ be placed without hiding something? Whether at the side or on the screen it must obstruct some view, and architecturally in a more objectionable manner in the latter case than any other. Moreover, a church is made for some other purpose than to be merely gazed at, and therefore the æsthetic must, if needs be, give way to the utilitarian. The much-abused Mr. Penrose and his coadjutors had a definite task before them—i.e., to impart some life to a cathedral which possessed little interest in a religious point of view hitherto, by adapting it to the requirements of a large congregation and hearty choral worship. It requires more cogent reasons than the taunts and ridicule of "C. B. A." to convince the public that they have been unsuccessful, or to convince those gentlemen themselves of the propriety of restoring the old organ to the screen, so happily done away with, I trust for ever.—I am, &c,

ECCLESIOLOGIST.

P.S.—"C. B. A.'s" reference to the "crane to lift something" fairly puzzles me. What *can* be the meaning of this witticism?"

BUILDING IN CONCRETE.

SIR,—With respect to "H. R.'s" letter, which appeared in the BUILDING NEWS of September 4, I beg to say that the wall he has built looks very well, but his house has fallen down. By what I have seen no practical man would have passed the work. If he had used Robin's cement, and had the proper gravel, and had made his walls 18in. on the first floor, 14in. second floor, and then his 1ft. walls, it would have stood. By the gauge it appears to me to be about half and half, but the main result of his failure is the use of the wrong gravel and not good cement.—I am, &c,

October 16. W. MAY, JUN.

SIR,—As you have taken some interest in building houses in concrete, you will, perhaps, be glad to have some account of a house that was lately commenced in that material at Twickenham. It appears that this structure, which was intended for a large and handsome mansion, has by some means come to grief. As an engineer who has had, perhaps, more experience than any other in constructing houses in concrete, I have been instructed to professionally examine the works and report on the cause of their apparent failure. I accordingly went to Twickenham one day last week and made a careful survey of the works. I was informed on the ground that the foundations were defective—that is, the soil was loose and sandy, and that the walls sunk in consequence. Owing to the large quantity of *debris* I was unable to verify by personal observation the correctness of this statement; but, as there was no difficulty in accounting for the accident by the evidence above ground, it will not be necessary to insist very strongly on the defective nature of the foundations.

I found the four outer walls of the mansion, and also a long inner wall, carried up to nearly 40ft., without a single joist or binder of any kind. These walls were only 12in. thick, and were pierced with a larger number of openings than I ever remember to have seen in any walls of the same thickness and superficies. The cement employed appeared to me some of the very worst that had ever come under my notice in a pretty wide experience. Some of the window openings were unusually large, and I could not find that any precautions had been taken to strengthen the arches over them.

Now, I have carried up in concrete 12in. walls, over 40ft. high without the least sign of weakness, but I have invariably carried up the cross walls simultaneously with the external walls, and have always built in the iron joists as the walls rose, thus well tying all parts together. And last, not least, I have always been particular in using none but the very best cement. If these precautions had been taken instead of the reckless system that was adopted at Twickenham I have no hesitation in saying that such an accident could not possibly have happened. I may also add, that I found a vertical pipe (I presume for the conveyance of rain water) was carried down one of the outer angles of the building, thereby much weakening a part that ought to be one of the main stays of the structure. Several other minor defects and errors in construction might be pointed out, but I do not wish to trespass too much on your space. I will, therefore, conclude by saying that in my opinion the cause of the failure is to be attributed mainly to the improper manner in which the works were carried on, and to the bad quality of the cement used.—I am, &c., W. E. NEWTON, C.E.

66, Chancery-lane, October 21.

[We have seen the building, and can say that the facts, as stated by Mr. Newton, are quite correct (with the exception of his statement as to the bad quality of the cement, the truth of which we had no means of ascertaining). We were as much surprised as he was at the absence of joists or any ties for the walls, and at the large openings for some of the windows. We believe that to these causes the fall of the building may in a great measure be traced; at any rate, it has not as yet altered the opinions we have before expressed regarding the use of concrete.—ED. B. N.]

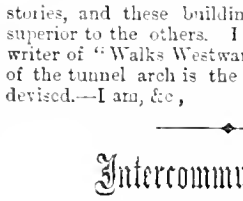
WALKS WESTWARD—STATION BUILDINGS.

SIR,—As a subscriber to your paper since the commencement, I think I may indulge in a few lines on the subject of the Metropolitan District Railway Stations. I consider the remarks in last week's journal too hard upon the architecture of the stations. We all know the great difficulty in working for a company and shareholders of a railway. They care little or nothing for architecture or taste, therefore ignore high art designs as foolish and expensive. They say we only want sheds, not architectural structures, as the company will not go to the expense. Now, under such circumstances, can any one employed as architect show his powers of design after receiving such instructions? I certainly say, No. From what I have seen of these stations, I consider they are well built, are of good proportions, and most convenient for their purpose: besides it is known by the profession that a small depth and frontage for a one-story building is a difficulty to get over when economy is the essential point. The Victoria and the Gloucester road are of two stories, and these buildings are most certainly superior to the others. I cannot agree with the writer of "Walks Westward" in saying the form of the tunnel arch is the ugliest that could be devised.—I am, &c, ALBERT EDWARD.

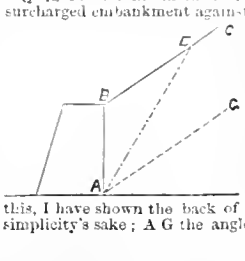
Intercommunication.

QUESTIONS.

[1079.]—SIZE OF GIRDER.—Can any of your readers inform me what size girder is required under the following circumstances? I am about to erect a warehouse which will be loaded with rather heavy goods. It is 40ft. long, and 15ft. 6in. wide, in the clear. As 15ft. 6in. is too long a bearing for the joists, I propose to insert rolled iron girders at distances of 10ft. apart, and so place the joists the longitudinal way of the building. It will appear as sketch. What size should the girder be?—INIGO JONES.



[1080.]—RETAINING WALLS.—I am much obliged to "Q. E. F." for his method of finding the pressure of a surcharged embankment against a retaining wall. I cannot see, however, how the line A C in his sketch can represent the natural slope of the earth or angle of repose, as that is evidently B D, which is the slope of the embankment when it is formed, or what it will become afterwards by the action of the weather. In the sketch I give with this, I have shown the back of the wall to be vertical for simplicity's sake; A G the angle of repose parallel to the slope of the embankment; A E a line bisecting the ∠ B A G; B A E therefore being the portion of the embankment to be retained. How is the moment of the pressure B A E found? and how or at what point does it act against the wall? When B E is level with the top of the wall the moment of the pressure is = tang.² ∠ B A E × weight of a cubic foot of the earth × $\frac{A B}{2} \times \frac{A B}{3}$. How must this equation be altered to suit the case of B E sloping upward at any ∠ ϕ with the horizon, or ray at *n* to I?—X. Y.



[1081.]—GEOMETRICAL TRACERY.—I should be much obliged if any of your correspondents would kindly tell me where I could get a book that would show the principle of setting out geometrical tracery. I want to know how the centres are got.—G. R., Carpenter.

[1082.] LIQUID GLUE.—Will any reader tell me a good recipe for making liquid glue?—R. JOHNSTONE.

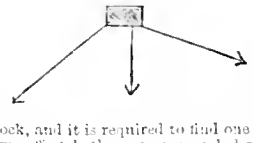
[1083.]—WATER SUPPLY.—Would any of the readers inform me how I can calculate the quantity of water that can be obtained from gathering grounds? I suppose that there are no springs or streams, but that the whole supply must be procured from the rainfall.—WATERWORKS.

[1084.]—REGULATING TIMEPIECES.—It has long been a puzzle to me to know what is meant by regulating timepieces or setting chronometers by the sun. I have a capital transit instrument, and believe it is by some observations of the sun that the matter is managed, but am at a loss to know how to proceed. If some of your "Intercommunication" contributors could set me in the right way to work I should be greatly indebted to them.—VERAN.

[1085.]—LAYING WROUGHT IRON JOISTS.—I am putting down some floor joists of a tee section, as represented in the cuts. Which way ought I to place them so as

to have them as strong as possible? Should they be laid in the position shown by 1 or by 2? They are 10ft. in length. What would be a safe load for one uniformly distributed over the whole length?—CARPENTER.

[1086.]—RESOLUTION OF FORCES.—Being a student of mechanics, I met the other day with a problem that I am unable to solve. Can any subscriber give me a helping hand? There are three (see drawing) acting upon one block, and it is required to find one that will produce the same effect both in power and direction as the three.—STUDENT.



[1087.]—SUPPORT FOR FLOORING.—Will "S. Lewis" or any of your correspondents help me out of the following difficulty? I want to add strength to a floor which is supported by timber beams, which are not considered sound. I wish to learn whether brick arches would be preferable to timber trussing? If so, what sort of arch would be strongest, and what the best way to construct same so as not to put too great a pressure on the side walls? The span would be about 20ft., and the height 11ft. I want to keep head room next side walls.—CLERK OF WORKS.

[1088.]—BOOKS.—Can you or any of your readers recommend a good work on the art of water colouring and shadowing; also a good dictionary on arts and science?—A STUDENT.

[1089.]—COLOURING DRAWINGS.—Will any of your numerous correspondents kindly inform me the best method to lay water colours on drawing paper without causing the paper coloured to crease?—INQUIRER.

[1090.] PERSPECTIVE.—Will any of your able correspondents kindly furnish me with a rule for determining the angle to which the arms of a "centrolineal" should be opened, assuming that the distance of the vanishing point and the position of the two pins are fixed? I have never met with a solution of this problem in any perspective book.—T. W. W.

REPLIES.

[1022.]—AREA OF A FIELD.—I most humbly apologise to "F." for having so evaded him, as I am sure in his calmer moments he would not have written things so easily disproved. He asserts that A F and F E are in the same straight line, and yet most unfortunately for himself he confesses that the distance from A to E is not equal to the sum of those two lines by about 2ft. Then, I ask him, is it possible to have between two points two distinct straight lines of different lengths? It is absurd. Again, he says that in the figure (September 18) the points A F E are in one straight line; but if he puts a straight edge to them he will find it a funny straight one—similar perhaps to the barrel of the gun warranted to shoot round the corner. And, as a further proof that they were not intended to be in a straight line, I call his attention to the previous figure (September 4), where it is shown in a more exaggerated form. Now, to assist his argument, he calls up "W. E. B.'s" letter, and because the figure is there divided into three triangles I am to acknowledge it five-sided; but, on the other hand, "R. L. B." divides it into four triangles, thus indirectly allowing six sides; while if "F." will turn to the next solution—that by "Another Young Surveyor"—he will find the two lines, A F, F E, are taken as two sides of a triangle. Surely, after this, he cannot call the figure five sided. I have one thing more to tell him, and that is,

his solution (October 2), of which he boasts, is wrong. I tried over his triangle C, and found it to be—not 85995 square feet, as he declares—but exactly as "R. L. B." has it; and, without going any further, I concluded his work was untrustworthy, and not only his work but his method also. He must be aware that there are 272¼ square feet in a perch. In conclusion, let me tell him he has evidently tried to screen his bad cause under shelter of a volley of abusive language and small wit.—J. M'Namara, Stratford-on-Avon, October 17.

[1054.]—PAYMENT OF SALARY.—Unless "L. Z. O." had a written agreement respecting the month's notice, he has no redress, as an employer can always dismiss an employé by giving him notice for the time equal to the intervals at which he pays his salary. Under the circumstances, "L. Z. O." could be dismissed at once if a week's salary were given him.—C. C. P.

[1063.]—RAILWAY CARRIAGES.—If your correspondent on the subject of railway carriages would communicate with me, I should be happy to furnish him with all that he requires.—T. Prescott, 287, Hyde road, Manchester.

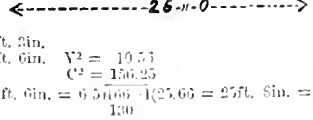
[1070.]—PARTY WALLS AND PARTY FENCE WALLS.—The legal interest of adjoining owners in a party fence wall is different from that in a party wall. There is no Act of Parliament which gives power to a building owner to raise a party fence wall without the consent of the adjoining owner, notwithstanding the many instances in which such power has been exercised under the supposed authority of the Metropolitan Building Act. To put the law concisely in the words of an eminent barrister—"If it can be ascertained what portion of the site of a party fence wall belongs to each house, the owners and lessees of the houses respectively will be entitled to build on such parts out of the wall as stand on the sites belonging to their respective houses; but if the separate ownership of portions of the site of the wall cannot be ascertained, the wall would be considered as belonging to the two parties as tenants in common, and neither would in that case be entitled to build on it without the consent of the other."—Purlin.

[1070.]—The legal interest in a party fence wall, if really "party," belonging jointly to the houses, is, I apprehend, the same as in a party wall, with the same rights and conditions; but a party wall is not always "party," even when it separates two buildings, but is sometimes in law an external wall. In like manner, a party fence wall may belong entirely to one house. "B. T." must make sure of his interest in the wall, and may then serve his notice upon the adjoining owner, pull down, build on half or all, as he may desire.—Lough.

[1073.]—WALLS OF BUILDINGS.—"R. P." will do well to use common sense, and not try to adopt too many rules in his practice. It stands to reason that a wall 80ft. long, unless well tied in with either cross walls, partitions, or joists, will require to be thicker than one only 20ft long. I think I may safely recommend him to adopt the thicknesses given in the tables of the Metropolitan Building Act, 1855.—Lough.

[1073.]—The question put by "R. P." is of some interest, as it touches upon the stability of long walls. It is often considered that the length of a wall has little or nothing to do with the calculation of its strength, and in determining the stability of retaining and other walls that dimension is theoretically neglected. But practically, it is very carefully taken into account, as the introduction of counterfoils and buttresses sufficiently points out. The usual increase of thickness in the lower stories of buildings is at the rate of half a brick whenever the length exceeds 65ft.—A. S. T.

[1074.]—RISE OF AN ARCH.—The following rule will, I think, supply "Carpenter" with the information he requires:—Let V = versier or rise of arch; C semi-chord or half span; R radius. Then $\frac{V^2 + C^2}{V} = R$. Example:



V = 3ft. 3in.
C = 12ft. 6in. $V^2 = 10.51$
$C^2 = 156.25$

2 V = 6ft. 6in. = 6.5)166.76(25.66 = 25ft. 8in. = radius.

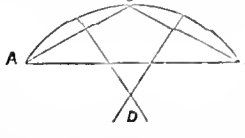
325
431
390
410
390
20

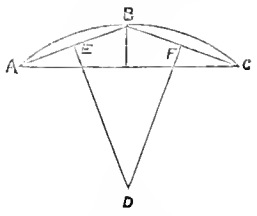
Geo. W. Usill.

[1074.]—"Carpenter" will find the following method both simple and accurate: Having fixed the point C equidistant from the extremities A and B, and having a rise



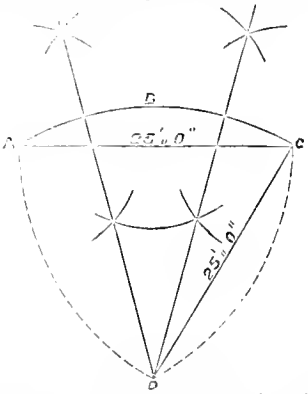
as required, join A C and C B. Bisect these lines by perpendiculars, which on being produced will meet at D. D is the centre of the circle, and of course the length from D to either of the points A C B is the length of the radius.—J. M'Namara.

[1074.]—The following answers "Carpenter's" question:—Join A B and B C. Bisect the lines A B and B C and draw from points of bisection two lines at right angles to the lines A B and B C. Then the point of contact obtained



by the production of these lines will be the centre from which the arc A E C may be struck.—Baby.

[1074.]—Bisect the points A B C; continue the bisecting lines till they meet at D, and the distance from those points to D is the radius. "Carpenter" and architects' assistants (architects themselves having little to do with it) may do



well to note that a pretty safe guide for the radius of an ordinary segmental arch is equal to the width of opening. In this particular instance it is correct, each being equal to 25ft.—H.

[1074.]—If "Carpenter" will multiply half the span by half the span, divide the rise, then add the rise and half the quotient; this will be the length of radius rod required. To illustrate what I mean, say an arch of 8ft. span by 2ft. rise—

Half span 4 0
4 0

Divide by rise 2)16 0 feet.
8

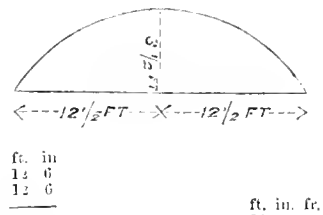
Add rise 2

Halve it 2)10

5 feet,

which is the length wanted above arch. For arch in diagram, 25ft. 8in. is the length.—E. H.

[1074.]—"A Carpenter" asks a method to calculate the radius of a circle, the span and rise of an arch being given. The correct and simple rule is this:—Square one half the length of the span and divide it by the rise, to which quotient add the rise, one half of which is the radius required. The following is the illustration from the given dimensions:—



ft.	in.		ft.	in.	fr.
12	6				
12	6

25.665 feet.
12
7.980 inches.

Thus the radius = 25ft. 8in. very nearly.—Robey Carpenter, Land Surveyor.

[1074.]—Divide the square of half the span by the rise of the arch; add this divisor to the quotient, and half the result will be the required radius. See Euc. III., Theorem of Equal Rectangles under the Segments of Intersecting Chords.—R. Johnstone.

[1074.]—"Carpenter" may find the radius of his arch by the following method:—Add to the square of half the chord the square of the versed sine, divide the sine by twice the versed sine, and the quotient will be the radius of the circle. In the example given—12.5 × 12.5 = 156.25 + 10.56¼ = 166.81 ÷ 6.5 = 25ft. 8in., the radius required.—R. C.

[1074.]—The radius of his arch is 25.66ft. The rule is, to square half the span and divide that by the versed sine or rise, and to the quotient add the versed sine, which will equal the diameter, half of which is the radius.—Another Chip.

[1074.]—In answer to "Carpenter's" question, the simplest method of ascertaining the radius of an arch, the span and rise being given, is to multiply half the span, 12ft. 6in., in itself; before multiplying, reduce the feet to inches, and multiply inches by inches; when the half of the span is multiplied, divide the product by double the rise, 6ft. 6in., reduced to inches, then add half the rise, 1ft. 7½in., to the remainder, and the product, 25ft. 3½in., will be the radius required.—G. W.

[We have also received answers to this question from "W. H. R.," "F. W. A.," "W. J. Dray," "D. O. E.," "Howell Howell, Neath," "Arthur Carpenter," and "Henry Hopkins, Banbury." The answers inserted were in type before those not inserted were received.—Ed. B. N.]

[1075.]—LIMITS OF DEVIATION.—I am sorry for "Farmer," but there is no help for him. The company can run the line wherever it pleases, but once having determined it, and sent the plans in by the end of next month, they cannot trespass beyond the limits of deviation without getting a new act, and seeking for what is termed a deviation. The limits of deviation are 100 yards upon each side of the centre line in the open country, and 10 yards when the line runs through towns or land continuously built upon.—Engineer.

[1077.]—CONTENTS OF SPHERES.—Under the supposition that by a part "A. B." implies a segment of a sphere, I give him two formulæ. 1. To three times the square of half the diameter of the base add the square of the height, and multiply this sum by .5236 × the height: *i.e.*, $(3 \times 4^2 + 2\frac{1}{4}^2) \times .5236 \times 2\frac{1}{4} = (3 \times 16 + 5.0625) \times 1.1781 = 53.0625 \times 1.1781 = 62.513$ cubic inches, nearly. 2. From three times the diameter of the sphere (9⅜in I believe) take twice the height of the segment, and multiply the remainder by .5236 × the square of the height: *i.e.*, $\left\{(3 \times 9\frac{3}{8}) - (2 \times 2\frac{1}{4})\right\} \times (.5236 \times 2\frac{1}{4}^2) = (28.125 - 4.5) \times .5236 \times 2\frac{1}{4}^2 = 23.625 \times .5236 \times 5.0625 = 62.023$ cubic inches. He will see from this that the two results differ, but so slightly as to be practically imperceptible. To say 62¼ cubic inches will, I suppose, be sufficiently accurate.—J. M'Namara.

[1077.]—To find the solidity of a segment of a globe:—To three times the square of the radius of its base add the square of its height; and this sum multipled by the height,

and the product again by .5236 will give the solidity. Thus: $4^2 \times 3 + 5.0625$ square of height = 53.0625 × 2.25 height = 119.390625 × .5236 = 62.5129312500 solid inches.—W. L. Lightfoot, Aberdeen.

[1077.]—Rule.—Three times the square of the radius of the base, add the square of its height, and this sum multiplied by the height and the product again by 5236 will give the solidity. Height 2¼in.; diameter of the base, 8in; radius, 4. $4^2 \times 3 + 2.25^2 \times 2.25 = 119.390625 \times .5236$ gives 62.5310125 solid inches, the contents of the segment of the sphere.—J. K. R.

[1077.]—The following is the general mathematical rule for finding the solidity of a sphere:—From three times the diameter of the sphere take twice the height of the segment, multiply the remainder by the square of the said height, and that product again by .5.36 will give the solidity of the segment. The diameter of the sphere is formed by considering the vertical section of the solid as the segment of a circle, and first finding its semi-diameter, as in my reply to 1075 in the foregoing. If "A. B." should want his question solved at length in figures, I will do it for him in my next, and, if necessary, investigate and demonstrate the rule. It is the shortest I have seen in twelve years' experience.—Robey Carpenter, Land Surveyor, and author of "Double Entry Book keeping Modernized."

[1077.]—To find the contents of a segment of a globe, "A. B." must multiply the square of the radius of the segment by 3, add the square of the height, multiply by the height, and the product multiplied by .5236, will give the desired content.—W. J. Dray.

[1077.]—To three times the square of the radius of the segment's base add the square of its height; and this sum multiplied by the height, and the product again by ·5236, will give solidity.—F. W. A.

BUILDING AND LAND SOCIETIES.

Operations have at length been commenced on the Milkwood Estate, Loughborough Park, Brixton, the property of the Suburban Village and General Dwellings Company. As briefly reported in a recent impression, the company has lately come under new management, and its success is regarded as certain. There are to be 650 houses erected on the estate, each to have a garden. The houses are to be in price from £200 upwards, payment to be made in the shape of rents extending over fourteen years. Mr. Habershon (Habershon and Pite) is the chairman of the board of directors.

The officers of her Majesty ship "Topaze," at present stationed off the South American Western Coast, are about to erect a monument to the memory of Alexander Selkirk on the island of Juan Fernandez.

WAGES MOVEMENT.

The masons' strike still continues in Aberdeen. Both parties seem determined to try their strength. Some hands have left town, but the great bulk of them are still hanging about. About 400 struck work, and about 130 remained in. As trade is still slack, the masters having no thing pressing, they may hold out for some time yet.

At a meeting, on Wednesday, the Bradford master builders determined on giving the notices for amended trade rules, as decided at the annual meeting of the General Association at Liverpool.

The masons of Liverpool and Manchester have given notice of their intention to commence work at eight o'clock on Mondays and seven o'clock on other mornings.

STAINED GLASS.

On Saturday last two stained glass windows in memory of the late Duke and Duchess of Rutland, erected in the Knipton Church, Yorkshire, were completed. That in memory of the Duke is of three lights, representing the raising of Lazarus, the Good Samaritan, and Abraham offering up Isaac. The window erected to the memory of the Duchess is of two lights, and represents the raising of Dorcas.

Two more stained windows have been inserted in the east end of the church of St. Teresa, Dublin, completing that end of the building. They are from the studio of Messrs. Early and Powell, of Dublin, the subjects being the espousals of the Blessed Virgin and the transverberation of St. Teresa.

A new stained window has just been inserted in the first bay of the north chancel aisle of St. Nicholas Church, Newcastle-on-Tyne. The window, which has been designed and executed by Mr. G. J. Baguley, of Newcastle, is of four lights, in the Perpendicular style. The subjects are our Lord's agony in the Garden, our Lord bearing the Cross, the Entombment, and the Marys at the Sepulchre. The subjects are surmounted by a Gothic canopy, and the top of the window is filled with simple tracery.

A memorial west window is about to be inserted in North Tawton Church, Devon, to the memory of the late vicar. It is the work of Messrs. Beer, of Exeter. The style is the Decorated, in four lights. The subjects are the six acts of charity.

Mr. Frederick Drake, of Exeter, has just completed a subscription window for the east end of the north aisle of Highweek Church, Devon, in memory of the late incumbent. It is a Perpendicular window in three lights. In the three upper panels one design, Christ blessing little children, is carried out with much detail and circumstance, and the three lower panels represent Faith, Hope, and Charity.

LEGAL INTELLIGENCE.

At the Thames Police Court, on Thursday week, Mr. Edward Pontifex, the proprietor of some white lead and chemical works at Millwall, was fined £5 for having used a furnace which did not consume its own smoke. Mr. Pontifex had been three times previously convicted.

Important to Plasterers.—At the Clerkenwell County Court, on Tuesday week, the cause of Fisher *v.* Crispe was heard. Mr. Boydell appeared for plaintiff, and Mr. Popham for defendant. Plaintiff, a plasterer, had contracted to plaster two houses belonging to defendant at £14 10s. each. While the work was in progress defendant sold one of the houses, and, according to plaintiff's account, directed him to do some extra work required by the purchaser of the house. Plaintiff did the work, but when he received the money on his contract a dispute arose as to the balance (£3 4s. 6d.), and defendant refused to pay it, stating that the charge was excessive.—Mr. Boydell called for the production of the contract.—Mr. Popham produced it, but objected to its use as evidence, as it was not stamped.—His Honour (R. H. Bagshawe, Esq., Q.C.,) on inspecting the document, observed that it was only signed by the plaintiff. Had the defendant also signed it the objection would have held good, but it would not in this instance, as the Stamp Act required the signature of the person sought to be charged. He would, however, take a note of Mr. Popham's objection. The items of the claim were then examined. The plaintiff produced a bill with the items in detail, but the defendant objected to the document as being different from the original claim. The original claim was then put in, and this differed so materially from the subsequent one that His Honour refused to hear any more, and nonsuited the plaintiff, with costs.

Defrauding Dust Contractors.—John Watson, John Simonds, and Richard Thompson, "flying dustmen," residing at Back-road, King-land, were charged at the Clerkenwell Police Court by Mr. Robert Dunham, inspector of nuisances to the parish of Islington, with collecting the ashes from the house No. 25, Norfolk-road, Islington, they not having been employed by Mr. Henry Dodd, the contractor for the removal of dust from that parish. The offence was committed so far back as the 24th of September last, but owing to the prisoners giving false addresses they could not be served with the process of the court, and hence their apprehension. The prisoners were seen on two occasions to remove the dust, and at the house above named the constable made them desist and go away. The prisoners denied in the most impudent manner that they were the men who removed the dust, but said they knew who did. The magistrates ordered each of the defendants to pay a fine of 40s., and 4s. costs, or in default to be kept to hard labour for one calendar month. The prisoners were locked up.

An Architect's Bill.—Jones *v.* Knight.—This was an adjourned case, in which defendant, an inhabitant of Ryde, disputed the balance of a bill of £13 3s., for drawings, surveyings, &c., as an overcharge, £10 having been paid into court. Plaintiff said the item in dispute included two sets of drawings of the premises in the Arcade, which he had been ordered by Mr. Urry, defendant's solicitor, to prepare for him. He followed his instructions implicitly, and on sending him the drawings he said they were useless, and he prepared others, which answered the purpose desired. He had, of course, charged him for the first set, which was included in the item of £5 5s. Defendant said he had not given orders for the plans to be prepared; the first he heard of it was when he received them from his solicitor, Mr. Urry, saying they were useless. His Honour said if he employed a solicitor it was at his discretion to act and order where necessary. Mr. Urry said he never gave orders for particular plans. He gave Mr. Jones instructions to prepare three plans of the three changes the premises had undergone. The plans were for the purpose of illustrating a case to the counsel in a cause now pending between Mr. Knight and Mr. Hughes. The plans first sent to him were not what he wanted, and he told plaintiff they were not, saying at the same time that they were rubbish. The plans he afterwards received were what he wanted. Mr. Hooper submitted that if plaintiff did not properly prepare the drawings he was not entitled to charge for them, but His Honour thought it would depend upon from what cause they were useless whether he ought to charge or not, and a Mr. Ball, surveyor, of Lond n, having given evidence as to the charge being moderate for the work done, he gave judgment for plaintiff.

Our Office Table.

Mr. Street is engaged in the repair of Bolton Abbey.

The chairman of the Associated Arts Institute has issued cards for a *conversazione* at 9, Conduit-street, Regent-street, on the 31st inst.

In a discussion that ensued at the meeting of the Islington vestry on Friday last, on the question of providing a steam road-roller for the parish, a striking proof was adduced of the economy that would accrue from such a step. In October, 1867, a piece of the road extending from Highbury-corner to Park-street was rolled experimentally. Not a single load of broken granite has since been laid down there, and the road is uniformly hard and smooth. On the other hand, from October, 1867, to August, 1868, no less than 747 loads of granite have been thrown upon the road from the "Cock" at Highbury to the "Angel" (exclusive of the part which had been rolled). Under this treatment the road has been either almost impassable for loose granite, or "lumpy" from its uneven consolidation. The road-roller is to be adopted.

Dr. Ballard, Medical Officer of Health for Islington, has, in accordance with the fifth section of the Artisans' and Labourers' Dwellings' Act, reported upon the condition of some of the dwellings of the poor in that parish. Parsell's-court, in the High-street, contains places, according to the report, not fit for human habitation. The report will be discussed at the next meeting of the vestry.

The Metropolitan Board of Works, deeming it desirable that their works along the new street from Blackfriars to the Mansion House should be carried on under the same management as those of the Metropolitan District Railway Company, made arrangements whereby the company have undertaken the formation of the sewer and subway at the same time as their railway up to the point where the railway and street will diverge, for the sum of £22,000. The portion of the sewer and subway to be so constructed by the railway company is that to the east of St. Andrew's-hill, while that portion west of Chatham-place is included in the Thames Embankment Contract No. 3, but there remained an intermediate space of about 700ft. and a short length of vaults, the execution of which has been given to Mr. Webster, at the rates of payment specified in the schedule of prices attached to his contract for the portion of the Thames Embankment from the Temple to Blackfriars Bridge, at the estimated cost of £10,000.

The Architectural Association will hold a *conversazione* at 9, Conduit-street, on Friday evening, the 30th inst.

A correspondent writes to ask when he may expect a further instalment of the "Architectural Society's Dictionary of Architecture?" We heard a short time back that it was in future intended to issue it yearly at Latter Lammas.

Three newly-built houses in Holloway-road, London, suddenly fell down on Sunday forenoon about half-past seven o'clock. The way in which houses are nowadays "run up" reminds one of the story of a Yankee in Paris, who, being at an hotel, tilted his chair after the manner of his countrymen, but overbalancing himself and falling against the wall of the apartment, went clean through it into the street. Archæologists find the domestic architecture of our ancestors a profitable study, but future generations will hardly derive equal satisfaction from the cheap houses of these days.

At a meeting of the St. Pancras Guardians Board on Thursday week, Mr. Culverhouse was elected Clerk of the Works for the infirmary at Highgate. There were five candidates.

A company is being formed in Plaistow having for its objects the erection and maintenance of a new town or public hall.

The approach road from the corner of Hatton-garden, Holborn, to the new market at Smithfield, will shortly be opened in its entirety. The new road crosses the Farringdon-road, the level of which is being raised slightly. One half of the road (that from Holborn to Farringdon-road) was opened some months since, and the remaining half (that from Farringdon-road to Smithfield) is now being paved, and will shortly be completed. This road is in a line with the road bounding the northern side of the new meat market, and, when complete, it will present one unbroken line from Holborn to Charterhouse square. Steps are being taken to carry it through Charterhouse-square into Aldersgate-street.

The Temple Gardens, the pride of the citizens of London, in about a week or a fortnight, it is expected, will outvie all previous years so far as the display of autumnal flowers is concerned. The green sward in both gardens is now in first-rate trim, and the many thousand pompones and crysanthemums are beginning to show flower. How very many other open spaces there are in the metropolis where the good example of the Templars might be imitated with advantage!

An address has been presented to the Emperor Napoleon by about 100 influential noblemen, M.P.'s, and other gentlemen, praying his Majesty to support the project of a submarine tunnel between England and France.

The council of the Architectural Museum announce the near completion of the premises in Bowling-street, Westminster, and invite the subscribers to the institution to call and inspect the new home for the collection about to be removed from South Kensington. The fund subscribed has been exclusively devoted towards defraying the cost of the actual building. It is now exhausted, and £1,000 more is required to pay the balance due to the contractor. The two shops in the front of the building have been let at a rent which will cover the ground rent payable by the council.

The works on the Milkwood estate, Brixton, which has become the property of the Suburban Village and General Dwellings Company, have been commenced. The surveyor has been engaged during the past week in marking out the roads, the Ecclesiastical Commissioners having given formal possession. It is proposed to erect on this estate about 650 houses, each to have a garden. Plans have been prepared, and when the estate is completed it will be a great improvement to the neighbourhood. The houses are to be in price from £200 upwards, payment to be made in the shape of rents, extending over 11 years.

New docks are in course of construction at Lynn. When finished, they will occupy an area of 7½ acres. The works are being carried out by Mr. Lawrence, the amount of the contract being £86,000. The front or river wall is carried down to the solid clay, rises to low water mark, and is constructed of large blocks of béton, weighing three tons each. The béton is composed of sea shingle, sand, Portland cement, and lime, mixed with water. Above low water mark the wall is carried up in brickwork. The entrance to the docks will be through a lock chamber 50ft. wide. The interior of the basins will be lined with concrete blocks. Mr. [illegible], C.E., is the engineer.

The Masborough Burial Board held a meeting on Saturday for the purpose of examining the competing designs for the proposed new cemetery. There were eleven competitors, residing in various parts of the country. The choice of the Board ultimately fell upon the designs of Messrs. Blackmoor and Mitchell Withers, of Sheffield and Rotherham, the estimated cost of carrying out which will be £1,500. The total expense of the new cemetery is expected to be from £3,500 to £4,000.

A *procès verbal* bearing witness to the completion of the works for rebuilding the grand cupola of the Church of the Holy Sepulchre at Jerusalem, in conformity with the protocol of September 5, 1862, was signed on the 26th ult. between the Governor of Palestine and the Consuls-General of France and Russia.

A correspondent, correcting a contemporary, who stated that the organ of St. Nicholas, Fribourg, was the largest in the world, gives some details of the best known large organs, which may interest those of our readers at present following the organ discussion in our columns. The Fribourg organ is said to contain but 64 stops, and about 4,500 pipes, and is not a powerful instrument, although it contains some good "solo" stops. The following instruments, among others, exceed it in size, viz.:—The Lucerne, 70 stops; Weingarten, 66 stops; Ulm, 100 stops; Stuttgart, 70 stops; Rotterdam, 92 stops; St. Mary's, Lübeck, 82 stops; St. Eustache, Paris, 68 stops; St. Sulpice, ditto, 100 stops; Notre Dame, ditto, 86 stops. I may also mention the three great organs at Hamburg, and the following in England:—Doncaster parish church, 96 stops; York Minster, 69 stops; Leeds Townhall, 85 stops; Alexandra Park, London, 87 stops; and St. George's Hall, Liverpool, 100 stops and 8,000 pipes. The latter instrument, by Willis, of London, is the largest and most complete organ in the world, but will be outdone by that (also by Willis) now being made for the Hall of Science and Art, South Kensington, which will possess 111 stops, and have pipes of burnished tin 40ft. long in front.

An experiment in the ventilation of mines by G. Goibal's new patent fans has lately been made at a colliery in the South Staffordshire district. The workings of the pit at which the trials were made are very deep and extensive, and the coal is of a fiery character. It is satisfactory, therefore, to learn that by the new method "it only took about twenty seconds to increase the ventilation from a state of nearly stagnation to that of 600,000 cubic feet per minute." The experiment was in every way a success, and we trust that the invention is destined to reduce to a minimum the worst risks to which our miners are exposed.

A company commenced two years since the irrigation of a large tract of land in what are called the Landes of the Pontlong, near Pau, in the Pyrénées, and a visit of the Emperor the other day has produced an account of the results obtained to the present time. Of the two thousand five hundred acres belonging to the company, one-half have this year produced fine crops of hay and grain, while the remainder are still covered with fern and reeds intermixed with grass, which affords poor nourishment for cattle during only about two months in the year. It would be satisfactory to know at what expense and in what manner this important reclamation has been effected, for few countries are without waste lands which require some similar treatment.

Trade News.

TENDERS.

Chiselhurst.—For the erection of a villa residence and stables at Chiselhurst, Kent, for Owen Edwards, Esq. John Tarring, architect, 69, Basinghall-street, E.C.:—

F. Saunders (accepted)	£3100

Darlington.—Darlington Union Workhouse. Mr Charles J. Adams, A.R.I.B.A., architect, Stockton-on-Tees. Quantities supplied by Messrs. Linsdell and Gifford, Gresham-buildings, City:—

For the whole of the works

Keswick	£15,167	9	6
Robson	14,927	0	0
Bellerby	13,916	14	2
Simpson	13,603	0	0
Sanderson	13,575	19	6
Johnson	12,872	0	0
Robinson and Marshall	12,310	5	0
M'Cormick	11,799	0	0

Lowest separate tenders.

M'Cormick, Brickwork, Plastering, Masonry	£6039	0	0
Wharton, Slating	771	6	8
Johnson, Plumbing, Glazing, Smith's work	1585	0	0
Garget, Joinery	2 08	16	4
Dryden, Painter	322	9	9
	11,696	12	9

The tender for the whole of the works by Mr. M'Cormick at £11,799 was accepted.

Durham.—For the erection of a new Masonic Hall, Old Elvet (City). T. C. Ebdy, architect:—

Punshon, Mason and Bricklayer	£973 0
Hutton, Carpenter and Joiner	340 0
Rule and Son, Slaters	48 4
Almond, Plumber and Smith	135 0
Mole, Plasterer	137 0
Maggison, Stainer and Glazier	61 14

London.—For pulling down and rebuilding house and shop, No. 11, Crotubie's-row Commercial road, E., for S. G. Frost, Esq. Mr. G. F. Payne, architect. No quantities:—

Searle	£505
Vickers and Harding	563
Moyl (accepted)	452

Durham (County).—For the erection of St. John's church, Holmside, to seat 150 adults. T. C. Ebdy, architect:—

Kell, Chester-le-street, Masonry	£376	10	0
Sanderson, Carpenter and Joiner	300	0	0
Rule and Son, Slaters	66	4	0
Laidler, Plumber and Smith	60	13	0
Hodgson, Stainer and Glazier	37	13	8
Wilkinson, Newcastle, Plasterer	43	10	0

Kirkleasham.—For the erection of Kirkleasham Free Schools. Mr. Charles J. Adams, A.R.I.B.A., architect, Stockton-on-Tees:—

Messrs. Shafto and Barry (accepted)	£3833

Leavesden.—For schools. To be executed in Burham bricks:—

Till	£48,540
Kirk and Parry	47,150
Higgs	46,560
Kirk	44,900
Chappel	44,350
Nicholson	43,750
Manley and Rogers	42,645
Webb and Sons	42,265
Henshaw	41,600
Mann (accepted)	38,845

Lewisham.—For erecting the new church of St. Mark's, Lewisham. W. C. Banks, Esq., architect:—

Mansfield	£13,250
Piper and Wheeler	12,578
Jackson and Shaw	12,559
Gammon	11,396
Naylar	10,793
Myers	10,587

London.—For rebuilding No. 35, Great Portland-street, W. Messrs. Bird and Walters, architects. Quantities supplied—

M'Lachlan	£1122
Kelly Brothers	1116
E. Brown	1099
Newman and Mann	1090
Williams and Son	1083
Ebbs and Sons (accepted)	1077

London.—For additions and alterations to 33, Beech-street, Barbican, for Messrs. Harris and Sons. John Belcher, architect and surveyor:—

Bottomley	£360
Bird	305
Fairhall and Weeks	302
Perry	291
Vickery (accepted)	270

London.—For the erection of a warehouse, workrooms, &c., at 4, Little Portland-street, for Peter Robinson, Esq. W. A. Baker, Esq., architect:—

F. Saunders (accepted)	£2720

Ramsgate.—For building two ale stores at the brewery, for Messrs. Thomson and Wotton. Mr. B. Adkins, architect:—

Goodchild	£1977
Cricket	1663
Belsey	1638
Wilson	1408
Epps	1195
Sollitt (accepted)	1187

Southend.—For tavern for the Commonwealth Land, Building, and Investment Society. Mr. Iron, architect:—

Johnston	£1485
Gunn	1475
Lake	1410
Wood	1393
Kilby	1335
Heard	1325
Crabb and Vaughan	1289
Wicks, Bangs, and Company	1250
A. and J. Smith	1247
Hobern	1235

St. Mary Cray (Kent).—For parsonage-house:—

Hollins	£1875	0	
Hill, Clayton, and Hobbs	1779	8	
Wright	1745	0	
Keys	1700	0	
Vaughan	1400	0	
Francis (accepted)	1375	0	
Smyth	1125	0	

Stockton-on-Tees.—For the erection of a villa, exclusive of boundary walls, stabling, and glazing, for R. Gray, Esq., Stockton on Tees. Mr. Charles J. Adams, A.R.I.B.A., architect, Stockton on-Tees:—

Messrs. Fletcher, Brickwork and Plastering	£445	0	
Bowman and Bouron, Mason	78	0	
J. Cooke, Joiner	397	0	
J. Atkinson, Painting	40	10	
J. Ibbetson, Slating	63	0	
M. Pearson, Plumbing and Smith	91	10	

Stockton-on-Tees.—For the erection of nine houses at Stockton-on-Tees, for R. H. Appleton, Esq. Mr. Charles J. Adams, architect, Stockton-on-Tees. The tenders submitted by the following contractors have been selected:—Maggison, Brickwork and Plastering; Bowman and Bouron, Masonry; Spiers and Middlemiss, Joinery; Messrs. Hind, Plumbing and Gasfitting; J. Ibbetson, Slating.

Watford.—For erecting a pair of semi detached cottages at Watford, Herts, for Thomas Dracott, Esq. Mr. Frank E. Thicke, architect:—

				Extra white facings.
Waterman (error)	£412	0	0	... £ 8
Allen	320	0	0	... 10
Cripps	317	0	0	... 13
Harley (accepted)	285	1	6	... 12

COMPETITIONS.

India.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

Melbourne, near Derby.—For designs for a new Wesleyan chapel. Mr. W. H. Adcock, Melbourne, near Derby.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

Portfield, near Chichester.—October 27.—For the erection of a new district church. G. Woods, Shopwyke House, near Chichester.

Sefton Park, Liverpool.—October 26.—For the supply and fixing of iron railing, gates, &c. J. Rayner, town clerk, Liverpool.

Hastings.—November 16.—For the purchase of ashes, cinders marine stores, and refuse of every kind. G. Meadows, clerk, Local Board of Health, Hastings.

Leicester.—October 28.—For the construction and erection of a treadmill. E. L. Stephens, borough surveyor, Corporate Offices, Silver street, Leicester.

Mold and Denbigh Junction Railway.—November 2.—For the completion of the above railway, and for the erection of passenger stations. J. Broughall, secretary, Shrewsbury.

Greenwich.—October 28.—For laying down granite kerb and Aberdeen dressed granite cubes. E. W. James, clerk to the Board of Works, Greenwich.

Northampton Waterworks.—October 27.—For constructing a covered reservoir. A. Milne, 2, Gold-street, Northampton.

St. Sepulchre, London.—November 2.—For warming this church with hot water. W. Fowler, vestry clerk.

Colchester (Essex).—November 6.—For erection of officers' quarters, &c. Commanding Officer, Royal Engineers' office.

Spilsby (County of Lincoln).—November 7.—For alterations and additions to the house of correction. Clerk of the Peace, Spilsby.

Wisbeach.—November 4.—For making and fixing about 54ft. elliptical cast iron culverts. W. Adams, C.E., Wisbeach.

Owlerton, near Sheffield.—November 4.—For the erection of a new church. Messrs. Blackmoor and Mitchell, Withers-street, James-street, Sheffield.

Tunbridge.—November 2.—For the erection of a villa. Mr. S. Cooper, 10, Lawrence Pountney-lane, E.C.

For the erection of gasworks for a village 50 miles from London, and for laying gas mains and services to same. Mr. A. Verey, St. Margarets, Herts.

St. Ives (Huntingdon).—November 3.—For tenders for the sewerage of the union workhouse. E. A. Wallingford, Clerk to the Guardians.

Dover Union.—November 6.—For the erection of new buildings, &c., for the infirmary. W. Cross, Clerk to the Guardians, Buckland.

PROPERTY SALES.

October 7.

At the Mart.—By Messrs. E Fox and Bousfield.—Leasehold residence, known as Thanet Lodge, Tulse hill, Surrey, let on lease at £65 per annum, term 98 years from 1838, at £12 12s. per annum—Sold for £1,060.

Leasehold residence and stabling, known as Harley Villa, Tulse hill, let at £70 per annum, term 96½ years from 1839, at £11 4s. per annum—£800.

Leasehold residence, No. 19, Gloucester crescent, Regent's Park, let at £60 per annum, term 72 years unexpired, at £10 per annum—£660.

Leasehold three houses and shops, Nos 63, 65, and 67, Caledonian road, King's cross, producing £110 per annum, term 66 years unexpired, at £24 per annum—£1,330.

By Messrs. Debenham, Storr, and Sons.—Two policies of assurance for £100 each in the Scottish Widows' Fund and Life Assurance Office, on the life of a gentleman aged 50 years—£40 each.

October 8.

At the Mart.—By Messrs. Beadel.—Freehold estate situate in the parishes of Thundersley and Laindon, Essex, comprising a farm known as Thundersley Lodge, with residence, gardens, orchard, cottages, homesteads, and grass, corn, and marsh land, the whole containing 421a. 3r. 30p.—£11,300.

Freehold and copyhold estate known as Diggins Farm, in the parishes of Willingdale Doe and Beauchamp Boothing, Essex, comprising a residence with stabling, homestead, buildings, and 167a. 2r. 15p. of land—£5,800.

Freehold house with two shops, situate in High street, Brentwood, Essex, let at £10 per annum—£550.

Copyhold farm, known as Lyers, in the parish of Willingdale Doe, Essex, comprising a farmhouse, homestead, buildings, two cottages, and 38a. 2r. 28p. of land—£1,070.

Copyhold two cottages and 6a. 0r. 34p. of land, in the parish of Willingdale Spain, Essex—£250.

A £100 share in the Chelmer and Blackwater Navigation Company—£30.

By Messrs. C. C. and T. Moore.—Leasehold three houses, Nos. 5 to 7, Bohn street, Edward street, Mile end, producing £54 12s. per annum, term 87 years, ground rent £7—£275.

Leasehold two houses, Nos. 11 and 12 Cologne street, Mile end, producing £36 8s. per annum, term 87 years at £7 per annum—£200.

Leasehold two houses, Nos. 23 and 24, William street, Cannon street road, and two houses, Nos. 2 and 3, Humber court, in rear, producing £79 6s. per annum, term 34 years, ground rent £10 per annum—£415.

Leasehold five houses, one with shop, Nos. 100, 102, 104, 106, and 108, Cornwall street, St. George's East, producing £82 5s. per annum, term 22 years unexpired, at £5 15s. per annum—£280.

Leasehold residence, No. 12, Alfred street, Bow road, annual value £32, term 35 years, ground rent £4 13s. 6d. per annum—£220.

Leasehold house, No. 1, Walter street, Portland street, Stepney, annual value £28, term 50 years, ground rent £2 per annum—£270.

Leasehold two houses, Nos. 5 and 6, Ann street, Green street, Stepney, producing £46 16s per annum, term 55 years unexpired, ground rent £6 6s per annum—£285.

Freehold two houses, Nos. 45 and 75, West street, Devonshire street, Mile end, producing £41 12s per annum—£400.

Fee farm rent of £ , arising from No. 140, Aldersgate street—£60.

By Mr. Newbon.—Freehold residence, No. 9, Stockwell common—£5,600.

Freehold residence, No. 8, South place, Albion road, Stoke Newington green, annual value £50—£650.

Leasehold premises, No. 31, New Gloucester street, Hoxton, let on lease at £28 per annum, term 63 years from 1823, at 8s. per annum—£295.

Leasehold house and shop, No. 32, New Gloucester street, let on lease at £24 per annum, term and ground rent same as above—£230.

Leasehold residence, No. 178, St. Paul's road, Canonbury, annual value £50, term 83¼ years unexpired, at £8 8s. per annum £460.

Leasehold residence, known as Alma Villa, Tollington road, Holloway, let at £52 10s per annum, term expiring in 1932, at £5 16s. per annum—£700.

By Messrs. J. and R. Kemp—Leasehold three houses and shops, Nos. 5, 7, and 9, Westminster road, producing £86 per annum, term 18 years unexpired—£1,015.

Leasehold business premises, No. 39, Marchmont street, Brunswick square, let at £70 per annum, term 37¼ years unexpired, at £13 13s. per annum—£585.

OCTOBER 9.

At the Mart.—By Mr. W. W. Mason.—Freehold property, known as the Stourmouth Brewery, Wingham, Kent, with two malt houses, stabling, residence, plant, goodwill, &c., also a hop plantation, two public houses at Margate, and a residence and cottage at Dover—£3,570.

OCTOBER 12.

At the Mart.—By Mr. Whittingham.—Freehold building land, fronting Hindman's and Upland roads, Peckham rye, in 46 lots. Lots 263 to 307 comprised previous sales. Lot 308 sold for £40; lot 309, £49; lot 10, £40; lot 326, £39; lots 345 to 352, £40 each.

Freehold building land situate at Hornsey, in 66 lots—from £60 to £250 per plot.

OCTOBER 13.

At the Mart.—By Messrs. Debenham, Tewson, and Farmer.—Freehold residence, with coach house and stabling, and meadow land containing about seven acres, situate at Claygate, Surrey—£3,000.

OCTOBER 15.

At the Mart.—By Messrs. Ellis and Son.—Freehold plot of building land, situate in Dennett's road, Peckham—£740.

OCTOBER 16.

At the Mart.—By Messrs. Norton, Trist, Watney, and Company.—Freehold estate known as Juniper Hall, situate in the vale of Mickleham, Surrey, comprising a residence with stabling, cottages, park, &c., containing nearly 50 acres, also a leasehold plantation, containing 4a. 2r. 13p.—£19,000.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

Robert Gooch, Hertford road, Kingsland, plumber, October 30, at 12—William Holdom Kimmins, Finchley, brick merchant, November 3, at 12—John Henry Lance, Croydon, builder, October 30, at 12—John Moore Smith, Cornhill and Stratford, Essex, architect, November 3, at 12—Valentine Cooper, Lewisham, builder, November 3, at 1—Thomas Graves, Winstanley-road, Battersea, builder, November 4, at 12—George John Moor, Aylsham-road, Old Kent road, plumber, November 4, at 2.

TO SURRENDER IN THE COUNTRY.

Charles Beech, Charles Tharme, and John Atkins, Hanley, timber dealers, October 28, at 12—William Briggs, Halifax, bricklayer, October 30, at 10—Richard Chapman, Cleethorpes, joiner—Thomas and William English, Peterborough, painter, October 31, at 12—William Shelton, Stonesby, Leicestershire, lime burner, October 26, at 11—Samuel White, Keyworth, Notts, joiner, October 28, at 10.30—James Broad, Bristol, builder, October 30, at 11—William Down, Hastings, bricklayer, October 31, at 11.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

December 11, J. Evans, West Ham, builder—December 18, J. H. Tozer, King's Cross-road, carpenter and joiner—December 10, J. C. Wilson, Lime-street, City, engineer—November 13, J. Moody, Leeds, builder—November 13, N. Gaunt and J. Sowry, Bradford, Yorkshire, iron and steel merchants—November 16, H. Mercer, St. Helen's, bricklayer—November 3, A. Lomax, Gorton, contractor—November 10, T. Baxendale, Eccleshill, slater—December 7, J. H. Wilson, Amble, Northumberland, tinner and plumber—November 11, W. J. Bowen, Tottenham, builder—November 11, J. F. Kent, Thornton Heath, carpenter and builder—November 13, W. Sexton, York place, Barnsbury, joiner—November 13, J. Hoar, Smith-street, King's-road, Chelsea, carpenter—November 20, J. Buck, Bath street, Poplar, master plasterer—December 1, T. Shakespeare, Latchmere grove, Battersea, engineer—December 3, T. Potterton, Balham-hill, builder—December 4, C. Mills, Dockhead, contractor—December 1, J. Owen, Bournemouth, builder—December 3, C. Saunders, Leytonstone, builder—December 4, G. Newton, Brighton, builder—October 30, W. Hampshire, Huddersfield, builder—November 26, W. H. Jackman, Haylands, Hants, builder—November 5, H. Williams, Redruth, carpenter and builder.

PARTNERSHIPS DISSOLVED.

Hardy and Hopper, Newcastle-upon-Tyne, timber merchants—Lacy and Flexman, Broughton-street, Battersea, builders—Simpson and Co., Stockton-on-Tees, builders—Phipps and Hay, Bath, architects—W. and J. C. Kemp, Exeter, timber dealers—Charlton and Co., Newcastle upon-Tyne, plumbers.

SCOTCH SEQUESTRATION.

David Smith, Glasgow, civil engineer, October 28.

THE BUILDING NEWS.

LONDON, FRIDAY, OCTOBER 30, 1868.

THE INSTITUTE OF BRITISH ARCHITECTS.

THE session of the Institute will be commenced with the ordinary general meeting, to be held on Monday evening, November 2 next, when the president, Mr. Tite, is expected to deliver the opening address, of which we need only say in anticipation that grateful recollections of his previous similar favours will ensure him a large and attentive audience. The members will reassemble after the recess, and will no doubt have abundant matter for discussion in the comparison of notes made in holiday rambles during the glorious summer and autumn of this exceptionally fine year. The "Transactions" will probably record many gleanings of impressions of architecture ancient and modern, at home and abroad, for as the quaint structures of Moscow supplied a description with illustrations from the graphic pen and pencil of Mr. I'Anson in the last volume, so, we understand, the next is likely to be enriched with recollections from Algeria, a ground of which also little has been previously known, by another valued and frequent contributor to the same pages. The indefatigable and zealous honorary secretary for foreign correspondence, Mr. T. L. Donaldson, is also expected to bring back with him from the pilgrimage on which he is now bound—to the East and the Holy Land—much that will prove of general interest, for though the route he is pursuing can hardly be termed untrodden, nor the earnest and loving spirit with which he will survey the scenes of sacred tradition be deemed novel, yet keen architectural eyes like his will perceive and garner something at every stage which is daily passed unheeded by travellers less specially endowed in such respect. In the meantime he has left his folio in the hands of Mr. C. C. Nelson, one whose experience and ability enable him amply to fulfil every duty to which he can be called, so that the Institute is not likely to suffer by the prolonged temporary absence of their active officer.

While, however, all will gladly welcome such foreign information, it should always be borne in mind that, as Mr. Seddon, the honorary secretary for home duties, has constantly urged, the "Transactions" of the Institute of British Architects should rather chronicle English works, and that in their pages the principal buildings of the day in this country should be both described and illustrated. As the Institute numbers now among its members so many foreign architects, and lays itself out for them, they may naturally look less for necessarily hasty and superficial remarks upon the antiquities and buildings with which they are familiar than for information as to what we are doing ourselves in our own land.

Another most valuable donation of books by the president will, we learn, be announced at the opening meeting. This, following his munificent gift of £500 for the purchase of books during the last session, cannot be otherwise than suitably received. The librarian, Mr. S. Kershaw, who, by the way, has been recently appointed to the honourable post of librarian at Lambeth Palace by the Archbishop of Canterbury, the hours of attendance at each post being arranged compatibly, is engaged upon the revision of the catalogue of books belonging to the Institute, and though we have called attention to the fact before it will bear repetition, that the library is now one of the most valuable and complete in existence as regards works on architecture, and we trust it will become correspondingly appreciated and studied.

In matters bearing upon the welfare of the profession, although it cannot be denied that the Institute has already done much, and is not chargeable with want of vigour or vigilance, much still remains to be done. In these days of reform, architects as politicians must look forward, not backward. One of the cries of the day, echoed on every hustings, is that for education, and it is one which needs to be raised loudly for architectural students as for others. Whether the provision for such be the especial business of the Institute or not, thus much is certain, that it behoves that body, as the first in position and established by charter, to take hold of everything that affects the interests of the members of the profession. If the education of the rising members be not its own concern, it is nevertheless its duty to learn whose concern it is, or should be, and to agitate till it is attended to. It was a sorry report given at the last annual general meeting as to the voluntary examinations that sufficient students had failed to present themselves to undergo them. It is clear that there is a fault somewhere, and the council in their report have pledged themselves to endeavour to amend what is wanting if they can discover it, and if it be the lack of some available recognition of the proficiency of those who pass creditably, let the students say so, and they may feel tolerably certain of the redress of any grievance they can point out. This is a subject the Architectural Association should consider well and advise the Institute upon. Failing any such step, should the disinclination among students to avail themselves of the advantages offered continue, it can only be attributed to their own apathy, and the Institute must perforce wait until another succession of them show a more anxious interest for their own welfare and improvement. Some time since an insufficiently considered scheme for some general system of education was brought forward under the auspices of Mr. Scott, and a committee of members of the Institute and several other bodies was formed for its consideration, and, as far as we can learn, the scheme was relegated to its proposer to be put into a more tangible shape. Nothing has since been heard of it; the committee has died a natural death, or become unconscious of its own existence. At the instance of Mr. Burges, the council of the Institute was during last session called upon to revive it, and the doing so will probably form an early and prominent position in the list of its agenda for the session. It may be desirable to learn, in the first instance, what may be the issue of the efforts of the Society of Arts in the direction of the establishment of a general scheme for technical education, in which the wants of the architectural profession, as of others, have been considered. The committee of that society having had Mr. Seddon and Mr. Spiers as representatives of the Institute of Architects and of the Architectural Association to assist them in their deliberations, their report has been issued and adopted by the society, and we presume the matter will not be suffered to rest there. It is, we imagine, in the direction of this or some other more powerful influence than its own, that the Institute must work, for it is evident that it does not itself possess the means to establish what the profession requires. The mere setting on foot drawing classes or courses of lectures—steps however desirable in themselves—would be simply palliatives in the stead of such a system as is demanded.

Another subject of vast general interest is, we understand, under the consideration of more than one member with the view of bringing it forward for discussion. It is that of competitions. The architectural profession is the only one which voluntarily submits to—nay, even covets—a system so degrading, and if anything could be done by the Institute to correct the evils which arise from it, great would be the boon it would confer. One example of which we have just heard will suffice to show its tendency. An architect of wide reputation for the erection of model buildings for the poor, finding himself unable to evolve successfully from his own consciousness the accommodation he was asked for, offered a premium of £5 for others to solve the problem for him, and, availing himself of the ideas thus economically obtained, is trading with them with a success which can hardly be called deserved. If such be the treatment that one professional man can deal to his brethren, what can they expect at the hands of the public, who are not less acute at discovering the use of an engine placed at their command, and who are bound by no feeling of etiquette or consideration of mercy?

Of course if moths will singe their wings in the candle they are quite at liberty to do so, nor need it matter to others whether the flame be from costliest wax or but a farthing dip. But in this case while injuring themselves they injure the profession as well, and if any means of restraining their suicidal ardour can be contrived it will surely be the interest and the duty of the Institute to carry it into effect. One of the most important works hitherto effected by the Institute, and by which it has earned wide and grateful thanks from the members of the profession, was in laying down fair and proper rules for the regulation of architects' charges. Although open to abuse, as everything else is, and liable to be taken exception to by employers, it is really remarkable that they have never hardly been challenged; certainly in no instance that we are aware of have they been set aside. They have been admitted as equitable in courts of law. They have been taken as precedents by provincial and American societies of architects—sometimes without due acknowledgment, seeing that but few additions, omissions, or emendations have been proposed in any such imitations of them.

ON THE SHADOWS OF SOME COMING EVENTS.

WE are not bitten with the prevailing mania, nor are we going to discourse much prophecy on the elections. Our purpose is the rather to quietly consider some of the art tendencies of the present day, and from the change which is going on around us to prognosticate the course most likely to be beneficial to the true student of the arts. That coming events do cast their shadows before them would somewhat imply that such events must be marching from the light, not to it, but, without questioning the exactitude of the simile, we will accept it in its popular form, and accord to it its popular meaning. In order, therefore, to best make out the nature, shape, and quality of the adumbrating substance, we shall study carefully all its shortening shadows, and, that we may know their true intent and import, must use that true mirror of the future, the past. No thoughtful observer of the architecture of the present can fail to remark the change which is taking place in its characteristics, nor fail to see that the ultra mediævalism which has somewhile been blindly trying to lead the blind has now fallen somewhat into the ditch, and is struggling to escape therefrom. With its still closed eyes it is groping after something solid, occasionally seizing it, but for lack of having its eyes opened, not recognising it when within its grasp. It will be instructive to trace the rise and progress of this past tendency, in order that we may see how the future is coming on, and lay some foundation for a scientific knowledge of æsthetic change and transformation.

Just about a hundred years ago a clever scholar rather than a learned man got tired of that political life so many just now are anxious to taste the bitterness of. He did a very unusual thing in those days, but, alas! a very common one since—he built himself a neat Gothic villa, and, being a man of taste, a lover of the arts, and still more, a fashion-

able talker on them, Strawberry-hill Gothic, both in literature and art, became the rage—quite the correct thing in fact; and though everybody could not build Gothic villas, yet everybody had a chimneypiece, and the newest things in the newest style thereon were fearfully and wonderfully made. Beckford followed afterwards, and then came Scott, and the public mind was thoroughly turned into the old forgotten channel. Then arose the first of the Pugins, John Britton, and a host of other illustrators of the past art history of the Middle Ages, and then followed, alas! the re-producers. Instead of learning the spirit of the lessons taught, they but repeated by rote. Because a thing had been done for one purpose and done well, it was supposed to do so much better for another now, and the consequence was it didn't. Then grew up the thinkers, and there are many now amongst us, but the evil was and is—they thought only how to translate modern ideas into mediæval art, and they have found that mediæval art is not elastic enough to hold them. Indeed, it is somewhat amusing to note how the exceptional circumstances and expedients of the past have become the types and generalities of to-day. Occasionally the true mediæval architect could not get that chief glory of his art, wall space, and then, because he had not strength enough to resist his arches, he used lintels, solid tympana, and such other expedients as he could; sometimes he could not have a buttress, and he was forced to lose his much-loved shadow, but all these excisions were very much of the nature of surgical operations to him, and never did he undergo them willingly. His art could not survive such frequent shocks, and when the time came that all these glories were to pass away it laid down its head and died. If we examine the present tendencies of the Gothicist we shall see that of all the chief beauties of mediæval art they are debarred the use; and a lopped, maimed, castrated representative is all they can produce. Nor can this poor Frankenstein of theirs speak plainly; it tries to be vernacular, and only reaches the "Gadzooks" and "I'fakins" of Mr. Harrison Ainsworth, nor tells its story better than it did under the hands of the too much abused Batty Langley. Was he not eclectic? and is not that good? Indeed, we think in many respects he was much less culpable than some of his revilers who have so much less invention: he sinned and called it sentiment, they sin and call it principle; the one perhaps was foolish, the other most certainly is false. Taking the experiment of revived mediævalism as a whole, a dispassionate and reflective observer must read its own handwriting on its own wall, and, weighing it carefully in the balance, finds it wanting. He sees it endeavouring to absorb the elements of inconsistent styles, to graft on its old stock scions of incompatible growth, and these attempts are to him so many foreshadowings that its days are numbered, and it behoves him to see whence comes its successor.

When the change of habits, of thoughts, and sentiments which were inherent to feudality took place in the fifteenth century, when new habits, thoughts, and sentiments replaced them, mediæval architecture died, and had more peaceful times succeeded in Europe, that which we call Elizabethan architecture would have refined itself and become in time as pure as it was imaginative. But the fates were against it; wars and rumours of wars were everywhere, and the fruits of Peace withered. Still, from the experiments then tried we learn somewhat of that which is coming, and, even now, whilst the pseudo-mediævalism of to-day is slowly dying, we see creeping into the works of the newer men who think a somewhat similar tendency. Instead, however, of seizing upon the late and debased Roman characteristics which formed the nucleus round which the Renaissance of England, Flanders, and France grew, we find them choosing with care and discrimination the refined details of the best days of Greece, blending it with the vigour and structural truth of true mediævalism, and finding in this union something which will express the sentiment of the day. The best works of the best men of France show this tendency greatly, and even in the works of our most rigid mediævalists we find it making way. As in the early essays of the Strawberry-hill days, so in ours, the little ornaments which surround our daily life, the papers on our walls, and the furniture of our rooms bear witness to the change in the current of popular taste, and shadow forth now as then the substance which is to follow. The works of our painters indicate the same change, too, and the growing fame of Leighton and Moore, and the tendency to classic arrangement in the works of Calderon, Yeames, and many others, prove how quickly the tide of mediævalism is ebbing, and indicate the current which will influence the succeeding flow. We would call, therefore, the attention of all the younger members of the profession to this coming change, and urge them to prepare for its advent by directing the course of their studies to the almost forgotten works of Greece and Lycia. Nor should they confine their studies to these alone, but examine carefully the modern works in that budding style to which our neighbours have already given the name of Neo-Grec—Greek on reasoning principles—and we trust they will bear in mind the latter. "Take the mixture, you can't do better," is the stock advice of most doctors, and one we would impress upon the young aspirants to the delusions and disappointments of architecture, but it must be the mixture. Let them note how and why revived mediævalism failed and avoid the error; let them strive to translate the ideas of the day, not into a dead but in a living language—a language, perhaps, containing root-words of many an older one, but having the more interest, the more force, and a stronger mental hold upon us for that very reason. Let them carefully watch the changes that are taking place around us, guarding against the danger of mistaking the shadow for the substance, but noting its growth and increase, and we have no doubt but that they will soon find the solid truth which flings it. Their study time is now, and if they rightly use it they will in days to come thank us for having thus early turned their attention to those coming events which already cast their shadows before them.

PRIZE DESIGNS.

FROM the time when the wily Goddess of Discord, indignant at not receiving a "card of invitation," threw down among the wedding guests the fruit of the Hesperides, competitions have ever been attended with jealousy, dissatisfaction, and vexation. All comparisons, however fairly and impartially they may be conducted, must, in proportion as they reflect credit upon the one party, bring at least disappointment to the other. It is no wonder, therefore, that they are "odious," and the epithet may be dated from the invidious inscription upon the golden apple, *detur pulchriori*. If we are to credit the records of heathen mythology it may be shrewdly guessed that the Trojan shepherd was, although less mercenary, equally corruptible as his modern successors, and that the prize offered to him in reality influenced his judgment and determined his selection. It is true that the claims of the fair rivals were pretty evenly balanced, and that there was just cause for hesitation, but the insidious promise held out to him by the laughing Queen of Love was an irresistible temptation to the youthful arbitrator. He accordingly earned the gratitude of the one and incurred the anger of the others, and the events that followed his decision are recorded in the only real epic poem that has been ever written.

It might be asked, Is it possible to decide a competition, and fulfil the motto *detur digniori*, to the satisfaction of all the competitors, or to the satisfaction of any but the successful candidates? The first question must be answered in the negative, but we think the second admits, in many instances, of an affirmative reply. Undoubtedly, where the candidates are numerous, there will be a large number who will be disappointed and dissatisfied solely because they are not successful, and, although their designs might be almost below contempt, yet they are so conceited that they are equally blind to their own defects and the merits of others. At the same time there are many who, though they naturally hope and wish for success, yet honestly desire to see "the best man win." These are also the very men who, we believe, will invariably be found to possess qualifications far superior to those of their rivals included in the former category. The remonstrance of the author of a rejected design is frequently not treated in the manner it should be, nor does it receive that attention due to it. This arises from two causes. In the first place, it is unwarrantably assumed that because his design was rejected therefore he is only actuated by jealousy and misplaced resentment against those more fortunate than himself; secondly—and this cause is a very true one—that the judges having committed themselves to a choice, whether bad or good, are bound to stand to it, and, therefore, ignore, or endeavour to smother, any endeavours that may be made to expose their partiality or their incompetence. The best-tempered man, the most diffident and modest, one who is more ready to allow the claims of others than to insist upon his own, even when they are superior in merit, feels bound to remonstrate against a decision wherein the incompetence of those entrusted with the arbitration becomes glaringly manifest. It is difficult to determine whether partiality or incompetence predominates in the majority of instances connected with prize designs and open competition. We may, perhaps, be accused of making a wholesale accusation against parties placed in the position referred to, but this is not the case. We willingly admit that there are exceptions, but confess with regret that those exceptions are rare. Can anything be more absurd for the members of a local board, a vestry, or other corporate body to constitute themselves judges of professional designs? Imagine men who have passed their lives in trade, not upon a mercantile but a much more humble scale, getting up in the presence of a surveyor, a man, perhaps, of unquestionable education, ability, professional knowledge, and experience, and propounding what they consider the merits of any particular case, utterly regardless of the ignorance they display, the absurdities they give utterance to, or the anomalies they propose. Yet, as a rule, it is men of this class to whose judgment—or we should say misjudgment—the sanctioning and carrying out of large and costly works are entrusted. It is they who advertise for competitions, pronounce upon the merits of the designs sent in, select the successful candidates, and award the premium.

The numerous letters we receive relative to the subject of competitive designs prove that the statements we have made are substantially correct. It is not to be supposed that all the authors of rejected designs are actuated by unworthy motives in publicly proclaiming their protest against the award of the judges. In fact, in very many instances the impartial reader can easily satisfy himself of the truth and force of the allegations put forward, and the experienced critic can readily detect from the tone of the communication by what motives the author is actuated. The truth is, that the whole system of competitive designs is conducted upon a false principle. The annexing mottoes to drawings and plans is a mere sham; the competitors might just as well put their name and address boldly in one corner. The error lies in the fact that even supposing the designs are submitted to

a disinterested and competent party, those who have the awarding of the premium are in reality acquainted with the names of the various candidates and the designs previously to his decision. A far better plan would be to have designs sent in anonymously, to let the examiner mark upon the back those which he considers deserving of the premium, and, after they had all been publicly exhibited, to let the candidates come forward and each claim his own design. Or an equally effective method would be to have a tracing made of a small portion of the designs to which the premiums had been awarded, and, after each competitor had claimed his own design, to identify the successful ones by means of the tracings. Whatever may be advanced to the contrary, it cannot be denied that there is an utter disbelief in the *bonâ fide* nature of all competitions of the class to which we allude. If one has any interest, or can make any with the authorities at head quarters, well and good, but if not, the intending candidate had better leave the affair alone, as it will simply result in loss of time, loss of money, and the gain of much disappointment and chagrin. Premiums have frequently been awarded to the authors of designs in which the actual conditions laid down in the public advertisement and private instructions have not only been uncomplied with but actually violated.

There is another and a flagrant weakness to which members of local boards, vestries, committees, and other prize-awarding bodies are peculiarly liable. It is a fondness for pretty pictures. An old hand at competition would never think of sending in purely working drawings, although the elevation in a good set of working plans gives a perfectly fair and honest idea of what the intended structure will really resemble. But the man who would be unable to distinguish in a working drawing an arch bridge, from one designed upon the horizontal principle would be able to discourse in a most edifying manner upon the different types of bridge construction when they were presented to his view through the medium of perspective, high colouring, deep shadows, blue skies, fleecy clouds, and, should the circumstances of the case permit of it—oh! lucky chance for the competitor—the clearest and most transparent water that ever flowed. There are no doubt many descriptions of architectural designs which absolutely require to be shown in perspective in order to display at one *coup d'œil* the relative proportions and general appearance of the structure. But even in these instances, the landscape, the rural or the urban accessories are very much overdone; sometimes they are developed to such an extent as to completely eclipse the real object of the drawing. The question will naturally arise, If these are the usually received opinions upon this subject, how is it that so many designs are always sent in, and so many competitors respond to the call? It would be difficult to give an exact reason. Young professional men who are striving to get on consider that they ought not to lose a chance. Others who have more time than business upon their hands decide upon sending in plans, and others, again, indulge in the delusive hope that true merit may after all be successful. Rejected candidates and disappointed competitors must inevitably accompany the selection of one or more to the exclusion of the many, but there is no necessity that they should impute and be able to justly impute unfairness, partiality, and incompetency to those upon whose shoulders rests the onus of proving the truth or falsehood of the imputation.

PETROLEUM FUEL.

A GLANCE at the large amount of space occupied by the intended fuel for locomotives and steamers is a sufficient proof that we have hitherto not succeeded in applying the principle of *multum in parvo* to these particular examples of mechanical invention. There are evidently two methods by which the storage room necessary for producing a certain amount of steam power during a given time may be diminished. The one consists in an economical construction of the machine itself, so that a smaller quantity of fuel will suffice for the generation of a given force, and the other in reducing the actual cubical contents of the fuel without at the same time diminishing its capabilities as a source of motive power. With respect to the first of these methods the ingenuity of mechanical engineers may be said to be exhausted, and, although some trifling improvements may yet be introduced, it is extremely improbable that the consumption of fuel per horse power will be brought within limits narrower than those to which it is now reduced. It is to the second, therefore, that we must look towards effecting a diminution in what might be termed the dead weight of all locomotive machinery. Hence there have been numerous attempts made to prepare artificial fuel in which the calorific element is utilised to a maximum and the percentage of the waste is a mere fraction. Recently the liquid form has been substituted for the solid, and petroleum, creosote, and other combustible fluids have been experimented upon with various degrees of success. France claims to be among the first in the endeavour to solve this important problem. About a month ago the Emperor travelled a distance of fourteen miles upon the footplate of a locomotive employing as a fuel petroleum oil. The production of steam was effected by burning a current of the oil, supplied by a pipe, upon a brick furnace, the quantity of the fuel being regulated by a small cock. In appearance the oil was a little viscous, and closely resembling in some of its properties the fixed oils of olive and colza. The application of mineral oils to fuel purposes was considered a success when tried on board the "Pueblo," a vessel belonging to the French navy. Both in our own country and America numerous attempts have been made to obtain an effectual and economical fuel from petroleum oil, but many obstacles have hitherto interposed to prevent the completion of the desired result. The complicated nature of many of the apparatus, the danger that might possibly arise from the mixture of superheated steam with the vapours of the oil, and other practical details not easily surmounted, have yet to be vanquished before a general opinion can be given in its favour. It is evident that steam vessels will especially benefit by the employment of petroleum oil fuel, since it will enable them to spare so much more space for the reception of cargo, and will also expedite their voyages by obviating the necessity for their stopping at the various coaling stations along their route.

THE RIGHT OF PROSPECT OVER OPEN GROUND.

THE recent decision of Vice-Chancellor Malins in the case of Potts *v.* Smith, 16 W.R., 892, involves in our judgment, says the *Solicitor's Journal*, a principle of some interest to owners and occupiers of houses in the suburbs of London and other increasing towns, with reference to such persons' enjoyment of the light and air derived from open spaces. The plaintiff, it seems, had taken a lease of a plot of building land situate in Cromwell-road, Kensington, and erected on part of it a house for his own occupation, while the remainder of the plot was surrounded by a wall seven feet in height and converted into a garden. Ere long, the defendant, who was occupier under the same lessor of an adjoining plot of land, was minded to convert it into a mews, and he ran up a wall along the plaintiff's garden wall to a height of 23ft. thereby shutting out the plaintiff's prospect in that direction over the adjacent ground. This was the injury complained of. The plaintiff moved to restrain the defendant from allowing the wall in question to remain of the height to which it had been carried, and rested his case for relief mainly upon the covenant for quiet enjoyment entered into with him by the lessor, which, as he contended, was binding on the defendant, whose title was also derived from the lessor. But the Vice-Chancellor declined to take this view of the case, and dismissed the bill without costs, adopting what we take to be the general opinion that the usual covenant for quiet enjoyment expresses little if anything more than is implied by the demise itself. It extends, in fact, only to defects in the title of the covenantor (Hunt *v.* White, 16 W.R., 478), and not to such acts as the interruption of the lessee's prospect by the lessor, or those holding or claiming under him. The case accordingly resolved itself into the simple question (it being agreed that there was no breach of covenant in the case) whether a man has any right, by any building he may erect upon his own land, to interfere with the access of light and air to his neighbour's house, in the absence of any covenant binding him expressly or by implication not to do so, or reservation in the deed of grant under which he holds his property.

The rule of English law upon this subject we believe to be that the owner of any plot of land, whether building land or not, has, in the absence of covenant or reservation, an absolute unqualified right to erect what buildings he pleases upon the whole or any portion of his land, building up to the very extremity of it if he pleases, nor can he complain when his neighbour exercises the same right in his own case. If he wishes to qualify or restrict his neighbour's right of building up to the edge of his property he must procure a covenant or reservation in that behalf. In short, except by express contract, the right of every owner of the soil to build up to the edge of his boundary cannot be restricted as a general rule. There are, of course, exceptions to the rule, in cases of restrictions on building established by statutory enactment, particularly in or near towns and near national works of defence. But with these exceptions we need not detain our readers.

"Free as air" is a common expression, and yet not true as applied to the enjoyment by persons of the air (and light) that come to them across the land of others. No man in England has or can have at common law an absolute right to any light and air except what come to him from above. To lateral or horizontal air and light he is not entitled. This may seem a paradox, yet it may pass for an assertion—somewhat broad, perhaps—of the existing law in the subject. In this respect our law differs from the civil law, in that the former does not recognise the right of prospect as existing or capable of acquisition by prescription over the land of another. This was held in Aldred's case, 9 Rep., 58b, on the ground, according to Wray, C.J., that a prospect is a matter of delight and not of necessity. Where you desire to retain the enjoyment of the prospect of an open space, or the access of light and air to your windows from property which is not your own, you must see that your right is established by a reservation in your favour, or covenant on the part of the owner of the land over which your prospect extends. To the operation of mutual covenants and reservations of this kind, and not to any fancied prescriptive rights of prospect, are we indebted for the squares and open spaces which it is the fashion to call the "lungs of the metropolis." Among the Romans a servitude of prospect did exist, and any, the least, interference with a neighbour's view was held to give him a ground of action—see an allusion to this in Cicero *De Oratore* i., 39. But this is not our law, as we have already shown, and we repeat that to prospect—*i.e.*, side light and air—a person is not absolutely entitled. Though he may have enjoyed for twenty years uninterruptedly the full benefit of the prospect over and the light and air coming from his neighbour's land, enjoyed them because his neighbour has not chosen to build on his land and exclude them, yet at any time his neighbour may build up to the line of demarcation and cut off his prospect, partially or altogether, and no claim of his to retain the prospect, based on prescription only, will be admitted. The loss of prospect is a sentimental grievance only, for which our law affords no remedy, and putting, of course, grants and reservations aside, his right of action does not arise until he can show that his light and air are seriously interfered with by his neighbour's buildings. A serious diminution of the supply of light and air, to the manifest inconvenience of the plaintiff, must be shown, or the court will not interfere. In Back *v.* Stacey, 2 C and P, 466, a case tried at the Norfolk assizes, 1826, Best, C.J., told the jury to distinguish between partial inconvenience and a real injury to the plaintiff in the enjoyment of the premises, and that there must be a substantial deprivation of light sufficient to render the

house uncomfortable in order to entitle the plaintiff to their verdict. This case has ruled cases of its class ever since. It was cited with approval in Dent *v.* the Auction Mart Company, 14 W. R., 709, L. R. 2 Eq., 238; and in Calcraft *v.* Thompson, 15 W. R., 387, Lord Chelmsford, C., said that the case had been approved by eminent judges and lifted out of the sphere of a mere *nisi prius* decision. So, too, in Roberts *v.* Macord, 1 Moo. and Rob., 230, Mr. Justice Patteson told the jury that the mere use of an open space of land for twenty years, for a purpose of which light and air were essential, did not preclude the adjoining owner from building on his land so as to obstruct the light and air. These and other such cases led to the now universally admitted rule that the court will not interfere to protect ancient rights, except where the injury is material. It is enough to refer the reader to Clark *v.* Clark, 14 W. R., 115, L. R. 1 Ch., 18, and Dent *v.* the Auction Mart Company.

We have already seen that the shutting out of a pleasant prospect gives no right of action. From the principle that we are of necessity entitled to none but vertical light, it follows that no person can claim an absolute right either for himself to see out of his property or for others to see into it In Smith *v.* Owen 14 W. R., 422, the court refused to restrain a person from obstructing the view of passers-by into his neighbour's shop, on the principle that a man has no positive right to look out of nor have others look into his windows. A similar case was Butt *v.* Imperial Gaslight Company, 15 W. R., 92, L. R. 2 Ch., 158, where the erection of a gasometer, which impeded the public view of the plaintiff's signboard and workshop, was held to be no ground for an injunction. To open a window overlooking your neighbour's ground so as to disturb his privacy is no ground of action, according to the dictum of Mr. Justice Blackburn in Jones *v.* Tapling, 12 C. B. N. S., 842; and in Attorney-General *v.* Doughty, 2 Ves. Sen., 452, which was a suit to restrain the defendants from building a wall so as to intercept the prospect from Gray's Inn Gardens, Lord Hardwicke is reported to have said, "I know no general rule of law which says that building to stop another's prospect is a nuisance. It depends upon a particular right—a right, it may be observed, depending on grant or covenant, and not to be prescribed for."

CORROSION OF IRON STRUCTURES.

AT a meeting of the American Society of Civil Engineers the following paper was read by William J. M'Alpine, C.E.:—

Formerly it was assumed that iron was subject to a rapid corrosion when immersed in water, or exposed to the alternations of the water and the atmosphere, and the every-day experience of constructors seemed to confirm this opinion. Wrought-iron bolts in wooden dams, and similar places, and in works wholly under water, frequently rapidly oxidise. Cast-iron water pipes in city streets are frequently found greatly corroded; and cannon shot, immersed in sea water for half a century, and sometimes less, have been found with the mass of the metal entirely changed from iron into plumbago, or deeply pitted by oxidation

During the earlier discussions of the subject the inquirer was frequently staggered in his belief in the generally received opinions by finding both wrought and cast iron which had been immersed many years but slightly oxidised, and wholly unchanged in its structure.

The cannon of the "Royal George," which had been submerged half a century, when first taken out, were so soft that the metal could be cut with a knife, but immediately hardened on exposure to the air, and were again fired. Some muskets and cannon, sunk in Lakes Erie and Ontario during the war of 1812, were, forty years afterwards, found to be but slightly rusted.

An iron steamer, the "Aaron Manby," which was launched in 1822, and kept in constant use for twenty years, was carefully examined, and no signs of corrosion found; and, ten years later, it is stated that she had required but small repairs for the whole period.

William Fairbairn also cites many cases where iron ships, which had been ten to fifteen years in salt water, showed no corrosion. This subject was much discussed in England in 1850, and the unexpected absence of corrosion in wrought-iron ships, even on the interior surfaces and iron parts, was then attributed to the vibration of the metal, as was noticed on comparing the amount of the corrosion of railway bars in the track with those aid outside of it.

Plumbago was obtained from cast iron immersed in acidulated water in 1822, and, forty years later, Dr. Calvert produced the same result by placing it in sea and foul water.

A dozen years earlier Mr. Mallet reported his well-known experiments on the corrosion of different kinds of iron in pure and foul atmospheres, and in clear, foul, acidulated, and salt waters, and arrived at the following general conclusions:—

That iron exposed to water holding air in combination corrodes on the surface either uniformly or in places, by rust or by the conversion of the iron into plumbago, and that corrosion depends upon the want of homogeneousness of the surface, or in its density or hardness, or in the combination of the carbon with the iron.

This subject was very thoroughly discussed by some of the most eminent engineers of the London Society in 1862, and numerous cases were cited both of corrosion and its absence in iron under water, and the cause explained.

The examples then stated, and numerous others, showed that cast iron of a particular description corroded rapidly, or changed its structure by a few years' immersion in foul or salt water, while other irons were entirely unaffected when exposed in the same way for twenty, thirty, and forty years. In the same structure, as in the case of the iron gates of the Sheerness dock, three pairs of gates had resisted the action of salt water for forty years, and a portion of the fourth pair, put in several years later, had been much softened and injured by its exposure.

Several of the leading engineers instanced numerous cases of square cast-iron piles, standing partly in and partly out of salt water, and a portion alternately wet and dry at each tide, which, after periods of eighteen, twenty-four, and thirty-one years, and intermediate periods, showed no signs whatever of corrosion or change—"the square angles of the iron were as sharp as when they left the foundry."

Mr. Simpson, the past president, said that in his practice he used great care in the selection of the iron, and such iron was practically incorrosive. The members stated that wherever this corrosion or decomposition had occurred it was wholly due to the quality of the iron. The engineer has, therefore, only to select that of a proper quality to ensure durability. My own experience and examinations, so far as they reach, confirm these opinions.

Cast iron, to resist corrosion to its greatest extent, should be as hard as the case will admit, of an even, close grain, and with the carbon combined, and not in the form of graphite. Impure soft foundry iron will corrode rapidly; close-grained grey iron of an even texture will resist corrosion in the most exposed places without sensible injury, and white iron of good quality may for all practical purposes be considered as imperishable in such situations. Care should also be taken not to place iron in contact with other metals, so as to produce galvanic action.

It is well known that many cast-iron water mains have corroded greatly, not only externally but internally. In the latter case the oxidation sometimes takes the tubercular form, where the rust is collected and aggregated in hard knobs.

In the early manufacture of water pipes they were often made from the worst quality of metal; it could hardly be called iron, but was a composition of cinders, sand, scoria, and iron of the softest kind, loose-grained, and in large crystals; indeed, precisely such a mixture as would offer the least resistance to corrosion.

Water pipes, placed in the streets of the city in earth alternately wet and dry, and saturated with mephitic gases from sewers and gas pipes, are exposed to corrosion more than under almost any other circumstances, and if made of the material just stated will be destroyed, where those of a proper quality of metal would endure a very long time. The internal corrosion, however, where the iron is exposed only to the action of pure water and a small amount of air in combination, will not occur to any appreciable degree if the iron is of the proper quality.

The strength of cast-iron pipes of the usual thickness is so far beyond the pressure of the water and occasional percussions that the manufacturers seem to think that the weakest metal will answer; and the engineers have not yet, in their specifications and inspections, required enough care in the selection of the metal best calculated to withstand corrosion.

The death of Herr E. Hildebrandt, the celebrated landscape painter, is announced from Berlin.

ST. CHAD'S MIDDLE SCHOOL, DENSTONE, STAFFORDSHIRE.

THE first stone of these buildings was laid on Thursday with great ceremony by Canon Lonsdale, in the absence, through illness, of the Marquis of Salisbury. These schools are a branch of the College of St. Nicolas at Lancing, and will be in connection with it for the purpose of educating and boarding at the cheapest possible rate—viz., at £30 a year—the children of the middle class of the great towns in the neighbourhood, such as Manchester, Nottingham, Stafford, Burton, &c. The building stands on a magnificent site, commanding the valley of the Churnet and Alton Towers, and the great Weaver Hill, and it is close to the Rocester Station on the Derby and Leek Railway.

The buildings will be arranged for 400 boys, with a training school for masters combined with the school, as at Hurstpierpoint. The general plan takes the form of the letter H, there being two quadrangles, opening the one to the east, and the other to the west. The quadrangle which looks towards the west is that which is now in course of erection, from the designs of the College architects, Mr. W. Slater and Mr. R. Herbert Carpenter. The style of architecture adopted is a rather severe type of Early Pointed Gothic, treated in rather a more ornate manner in the principal buildings, such as the chapel, dining hall, great school room, &c.

The material used for the outer walls is Alton stone, in random-coursed work, with bands of red Alton stone. The walls are hollow, the inner thickness, as well as all the inner walls, being of brick made on the ground. The roofs will be covered with brown tiles. The contractor is Mr. Bromwich, of Rugby, and the clerk of works, Mr. Beckensall. The ultimate cost of the building will not be less than £50,000.

The dimensions (inside) of the western quadrangle, or "Lonsdale Quad" as it will be called, in memory of the late bishop of the diocese, are 211ft. long and 160ft. wide. The eastern or "Chapel Quad" will be about 160ft. square.

The central cross block of buildings includes the great school room, 100ft. long and 35ft. wide. It has a lofty open-timber roof; the height from the floor to the ridge of it is 62ft. Below this, on the ground floor, is the principal entrance in the centre, a large boys' day room, class room, visitors' and porter's lodge. The school room is reached at the south end by a wide staircase. A cloister on the ground floor, 10ft. wide, joins the two wings.

Each of the wings is 211ft. long and 40ft. wide, with additional projecting blocks at the western end. These wings are about 65ft. high, and are in three stories. The lower story of the north wing has seven class rooms, with a cloister 8ft. wide along its entire length. The two stories above have each two dormitories 104ft. long and 17ft. wide, with large lavatories attached. At the western end of this wing is the head master's house and its offices, besides masters' rooms on the several floors.

The south wing is of the same general dimensions, but on the ground floor there is a gymnasium 125ft. long and 17ft. wide, and eleven small rooms for the masters' training school, also the boys' library, 30ft. by 27ft., and master's library, 26ft. by 22ft. They have a cloister connecting them with the second master's house and chaplain's rooms. The dormitories are the same as on the other side, each for 50 boys, and adjoining each dormitory is a junior master's sitting and bedroom, and a sick room.

The general height of these wings is about 65ft. The lower end is somewhat higher, and is finished by pyramidal roofs with stone dormers rising into them.

At each of the inner angles of the quad (where the wings join the central building) is a lofty tower with a tiled spire. The height of these is about 90ft. They are to contain the tanks for the water supply, and are so placed and arranged as to prevent the possibility of any spread of fire. The towers are simple and massive; the upper stages are corbelled out on bold arched corbels.

The wings of the chapel quad are not yet commenced. The chapel itself will form the southern side. It will be apsidal, and of grand and lofty proportions, with an ante-chapel opening into the cloisters. The campanile will stand on the north side near the apse, and will be massive, lofty, and simple in outline. The upper stage will be octagonal and finished by a low stone spire. The dining hall will join the northern wing. It will be 100ft. long and 35ft. wide, and entered from the cloisters by a grand staircase. It will have a

lofty open timber roof. Under the hall will be rooms for the masters' training school, music rooms, and other rooms for occasional use. The kitchens and offices will form, together with the laundries, engine house, workshops, gas house, &c., a separate quadrangle to the north of the general building.

The works are being rapidly pushed on, and the whole of the foundations and basement of the "Lonsdale Quad" are put in, and the building itself is rising some 2ft. or 3ft. above the ground. Great care was required with the foundations, the soil being a mixture of clay and shale, with a sharp fall in some places to the west. This portion of the work was, therefore, executed by a schedule of prices, the contract commencing at the ground line. The contractor is Mr Brogwich, of Rugby, and the architect's clerk of works is Mr. Beckensall.

BRADFORD HOUSE OF RECOVERY COMPETITION.

(From the *Leeds Mercury.*)

ON Saturday the plans prepared by Messrs. Lockwood and Mawson, of Bradford and London, Messrs. Andrews, Son, and Pepper, of Bradford, and Mr. E. Birchall, of Leeds, the architects selected to compete, were thrown open to public inspection at the Infirmary. The instructions issued to the architects were that the general arrangement of the hospital should be that known as the pavilion or block system, and on this arrangement they have been prepared. Messrs. Lockwood and Mawson present two handsome designs, the one Gothic and the other Italian, both of which look costly, but it is stated they could be brought within the amount fixed upon. Their designs illustrate the pavilion principle, developed in two modes of arrangement, both with the pavilions on lines from north to south, and, therefore, with east and west aspects to the wards, as recommended by the best authorities. The buildings are two stories in height, and it is shown how the pavilions can be reduced to one story, but, however desirable this may be in a sanitary point of view, the architects state that it would unquestionably be attended with extra expense. Each ward, to contain twelve beds, would be 60ft. long, 25ft. wide, and 16ft. high, with 24,000ft. cubical contents, allowing 2,000ft. to each patient, and also a private ward, containing nearly 3,000 cubic feet. A one-story building is included in the design, separated from the main structure, to contain ten persons of each sex. Whether the wards were constructed either one or two stories in height, accommodation would be found for 60 patients. The architects state their opinion that "£100 per bed is sufficient for the costs of the sixty patients provided for in the design, or the sum of £6,000" for the structure, and the separate building, for twenty patients, they estimate at £50 each, making an extra sum of £1,000. Mr. E. Birchall's design is Gothic, two stories in height, with the administrative department in the centre, and the wards at either side, connected with the central building by corridors. He gives accommodation for 52 patients, the wards on either side of each story for 12 patients, who have each rather more than 2,000 cubic feet of air, and a small ward is shown, capable of accommodating one patient. The wards run nearly north and south, to obtain the most light and air. Mr. Birchall states that there is nothing of outward show in his building, and that it is simple in design. He considers that it could and ought to be built at a cost of £100 per bed, but thinks that the sum might advantageously be raised to £150 per bed. He has also furnished a plan showing the wards one story in height. The selected design, by Messrs. Andrews, Son, and Pepper, is treated in a different manner from the others. Their first design shows a two story building, but in their second the wards are only one story. The architects state that the building has been designed on the exterior as cheap as is compatible with the appearance of a public charity, their great aim appearing to have been utility, and the desire to afford the most complete accommodation for all the departments connected with the specific character of the hospital. In the centre of the front pile of two stories, which partakes somewhat of the Gothic in style, is the administrative department, where apartments for the board room, the waiting room, the surgeon, matron, and other officials are located. The front faces to the north, and affords a pleasing aspect in the direction of Undercliffe. The convalescent wards are placed right and left of the centre, in sufficient proximity, and far enough removed from the administration to prevent any fear of contagion. The acute, or fever hospital wards four in number—two for males and two for females—are in the rear, and on the south side of the administration, each ward having a south, east, or west aspect, and shut out from the north. The wards are each 60ft. long, 25ft. wide, and 16ft. in height, lighted by five windows on either side, the space between each ward being three times their height, and they will each accommodate twelve patients. The wards will be warmed by Pierce's patent stoves, Sheringham's ventilators and other means being used to secure a proper supply of fresh air, and the top of each window fitted with fixed open louvres of glass. The wards are attached by closed corridors, of wood and glass, roofed with slate, and another corridor leads from the administration. The convalescent wards are divided, so that the patients can be separated according to the nature of the disease from which they are recovering. Great attention has been paid to drainage and other appliances essential to the peculiar character of the hospital. Each patient will have more than 2,000 cubic feet of air space, the walls of the wards will be covered with cement, the floors of oak, the roof and window frames of iron, the material used being chosen for its non-absorbent character. The mortuary, post-mortem room, ice-house, and other necessary outbuildings are detached. Sixteen patients can be accommodated in the convalescent, and 52 in the acute, wards, and the cost of the building will be about £110 a bed, or £8,000. The cost per bed could be reduced were the acute wards erected in proportionate size to the administration, the latter, as well as the convalescent wards, being in excess in regard to size in proportion to the other parts of the building. Should it be proposed at any future time to enlarge the acute wards this could be effected by lengthening them, and it would not necessarily increase the cost of attendance, as the nurses required for the smaller would be sufficient for the enlarged wards.

THE ORNAMENTATION OF IRON.

THE *Mechanics' Magazine* has an article on this subject, in which it says that since Zimmerman, of Berlin, began to make his exquisite iron castings, many things both useful and ornamental have been produced in cast iron. But iron being so liable to rust, it is desirable to protect it from the influence of the atmosphere. This is usually effected by means of a bronze paint. The bronze paint used to coat the Berlin castings is made of ferrocyanide of copper, which forms a rich brown paint with a metallic lustre. The ferrocyanide of copper is easily made in the following manner:—A solution of sulphate of copper is taken and to it is added gradually a solution of ferrocyanide of potassium, when a brown precipitate will be produced. This, when mixed with a suitable vehicle, is used as a basis for all the different-coloured bronzing, whether yellow, green, or brown.

The French use the green bronzing very much, which may be produced in the following manner:—When the ground has been produced with the above paint, and before it is quite dry, it is dusted over with copper bronze powder, and allowed to dry thoroughly, and then the loose powder is brushed off, and the article is polished; it will then appear like bright copper. The only thing required to produce the green tint is to wash the articles gently over with a solution of acetate of copper, and allow it to dry gradually. When perfectly dry, the higher parts of the article must be rubbed with a piece of clean rag to cause the brown copper colour to appear. The article will then look like a bronze which has become green by age. The common brown bronze is produced by brushing the above bright copper-coloured bronze over with black lead; and the pale or yellow bronze is produced by using yellow bronze or brass powder in place of the copper powder above referred to. Those who wish a more solid and durable bronze than bronze paint and powder will produce, coat the iron by electricity with copper or brass, and produce the different colours by the same means as those used to colour the copper and brass colours produced by the powders.

An easy method of coating cast iron with copper is that of M. Oudré, who first coats the cast iron with a metallic paint, and then electro-deposits copper upon it in a bath of sulphate of copper. A modification of his process is sometimes used—a brass powder being used instead of copper powder. This brass powder is produced in the following manner:—Equal parts of copper and tin are melted together, and when cold the alloy is powdered in a mortar and sifted; this can easily be done, for this alloy is as brittle as glass. This powder is mixed with the ferrocyanide of copper paint, which makes a very good conducting surface, and takes the copper well in the sulphate of copper bath, and the paint adheres very firmly to the iron.

For brassing iron the method is not quite so simple. For brassing direct on the iron the iron is required to be scrupulously clean, or the deposit will not adhere; but the easiest way is first to coat the article with copper by Oudré's process, and then, after thoroughly rinsing it in clean water, transfer it to the brassing solution, which is formed and worked in the following manner, according to Morris and Johnson's process:—Dissolve 1lb. of cyanide of potassium, 1lb. of carbonate of ammonia, 2 oz. of cyanide of copper, and 1oz. of cyanide of zinc in 1 gallon of water, and work the solution at 150 deg. Fah., with a large brass anode and a powerful battery. To increase the copper in the deposit add cyanide of potassium, or increase the heat. To increase the proportion of zinc add carbonate of ammonia, or lower the temperature. We have tried this method of depositing brass, and have found it a very good one, but the electrolytic processes are very little used for bronzing, because they are more difficult, consequently more expensive.

MEGALITHIC MONUMENTS.

SIR HENRY DRYDEN recently gave a lecture before the Architectural Society of Northampton, on the Megalithic Monuments of Brittany. Sir Henry stated his belief that it was due to the peculiar promontorial position of Brittany as a part of France that so many of these ancient remains had been preserved. The part in which he had been at work with Mr. Lukis was Quiberon. Of megalithic monuments there were four kinds—*menhirs*, which meant tall stones or pillar stones; *dolmens*, or chamber tombs; *circles*, of the three principal of which Sir Henry exhibited drawings—the circle of Ménec, the circle of Kairverin, and the circle of Kerlescant, and the monumental lines of Erdeven, the principal part of which was near Carnac. In dealing with these monuments a difficulty sometimes arose from the use by the French of the same word to denote a different thing. Thus what we called a cromlech the French termed a dolmen, and what we called a circle they called a cromlech. Sir Henry strongly advocated a systematic survey of these old ruins, as they were fast being destroyed. He did not intend to say anything about the dolmens, as Mr. Lukis had written much about them. The lines about Carnac were all he should describe. Of these he had only planned part. Some of the sets of lines had circles at their heads, others had not. Kerlescant had one which was not placed symmetrically with regard to the other, and Kairverin had no circle, and he did not think it ever had, as in other cases the circles were on the highest grounds, but in this case the lines went up to the point, and the ground began to sink directly after. The enlightened owner of Kerlescant was carting it away as fast as he could, and since his (Sir Henry's) plan was made, the greater part had been removed. Ménec consisted of eleven lines—in his opinion, all that ever existed. Erdeven also, he thought, consisted of eleven lines. He exhibited a drawing representing the circle of St Pierre, of a diameter of 180ft. Ménec was nearly one mile long, but Kairverin was the longest of them all. St. Barbe was only 900ft. in length but it was not exactly known if that had ever been completed. He believed that it had been, and at the top of it there was no circle now, but three enormous blocks, whether part of a circle or not he could not say. The circle of Ile Lanic was on a small island, about a quarter of a mile from the coast, the whole of which was covered with fragments of Roman pottery. Its diameter was 165ft. All writers who had mentioned these lines had treated them as if they were so many parallels, and some authors had favoured the hypothesis of their having existed for the purpose of serpent worship; that, however, he did not believe. In the case of every set of lines the head was wide and the tail small. The stones began by being some 8ft., 9ft., or 1 ft. in diameter, and decreased in size till at the end they were not more than 4ft., and none of them were set with mathematical regularity. The Great Menhir Locmariaber was

67ft. 5in. in diameter, and when it broke the two fragments oddly fell in opposite directions, as shown in his diagrams. In one dolmen a gold collar had been found, and that fact had resulted in greater damage to the monuments than the ravages of 200 years. In reply to some questions, Sir Henry stated that in many of the *dolmens* Roman statuettes, coins, &c., had been found, and he further stated that in Constantia, Algeria, there were thousands of dolmens only a few feet high. Some of them were 8ft. high, 17ft. wide, and 65ft. long.

STEAM ROLLERS FOR METROPOLITAN ROADS.

THE question of having steam rollers in metropolitan parishes has made (says the *Parochial Critic*) two steps in advance during the past week. At Islington a very full vestry gave the subject their attentive consideration, and though they did not like to bind the hands of the Highways Committee, to whom the consideration of the matter was to be referred, the speeches were generally in favour of a steam roller being either bought or hired for the use of the parish. Mr. Elliott, who brought forward the motion, set forth very clearly the experience of the parish in road-rolling. Out of 70 to 80 miles of road in Islington, only some 5 or 6 are cubed, and the making and keeping of the roads in repair costs some £30,000 a year. In a parish so circumstanced the present question assumes increased importance. If a good heavy roller were used Mr. Elliott believed some £6,000 per annum, would be saved, independently of other advantages. The most important part of Mr. M'Adam's discovery was that the material should be rolled so as to form one solid mass, and it was strange that they had got into the habit of leaving out this most important process. It was like playing "Hamlet" without Hamlet. From the books he found that 747 loads of granite had been spread from the "Angel" to the "Cock," at Highbury, yet of that immense quantity not a load had been required on that part of Upper-street where the roller had been tried in October, 1867. This practical result outweighs a thousand theories The vestry accordingly referred the matter to the Highways Committee to examine and report.

The same subject was discussed at the St. George's Hanover square Committee of Works. The surveyor, Mr. Tomkins, at the request of the vestry, prepared an elaborate report of the comparative cost of rollers by steam and horse-power. This report, of which we gave an abstract at the time, was postponed from the 26th of August, and now came on for consideration. The vestry have already sanctioned the use of steam power, but the great expense, £760, for one of Moreland's, £530 for one of Aveling and Porter's steam rollers, still deters them. The charge for mere hire of the roller would also be very high. After a long discussion the vestry could not make up their minds to incur the large outlay, and adjourned the question for a month. The surveyor, in the meantime, is to see what terms he can make with Messrs. Aveling and Porter. The present is an excellent opportunity for the parishes of Islington and St. George's to combine for the purpose of purchasing a roller. Surely £500 is not a large investment, when £5,000 can be saved by it. If the two parishes have not work enough to keep the roller in constant use, the Paddington vestry and the Westminster Board of Works are willing to hire it. This would further diminish the outlay, which would thus hardly amount to £200 for each of the purchasers.

GRANITE ARCHITECTURE.

A MATERIAL like granite, says a writer in the *Athenæum*, should be moulded in quite another manner from that which is proper to soft stone, as to which, to put it on the lowest grounds, we may say that the cost of working anything so hard as granite dictates such a difference, if the eye is not to be offended by the appearance of labour wasted and texture and surface misunderstood. The apt treatment of granite is in rounded contours and with extreme breadth, such as suggests immutable repose in design, which the Egyptians employed so widely for their monumental works. One would say that the veriest tyro in architecture would surely go to the Egyptians to study the best treatment of vast surfaces and long sweeps of architectural engineering in such an obdurate and monumental substance as monotonously grey granite. A true student would as surely do this as he would go to the Gothic architects for the right treatment of sandstone, with its lively colour and its facility for working in delicate and elegant contours. Unfortunately, the engineer of the Embankment has given to a material and a subject which are Egyptian in vastness, horizontality and character, certain mouldings and rich and broken surfaces, which are, if anything, Gothic in many of their details and questionably Palladian in their general aspect or composition. We do not like balusters in any position, but it is possible to make them less inelegant than those of Somerset House without departing from the ruling contour of these models. The balusters of the embankment are, without regard to the material in which they are wrought, inferior to the model, and sin needlessly against the nature of granite in being richer or more broken in their outlines than those which were wrought in tractable freestone by Sir William Chambers. Surely this was a grave error. Grand as is the design of Waterloo Bridge, it would have been grander if the balusters—which are ugly even in their details—had given place to a lower and solid parapet, like that of London Bridge.

A larger application than the above of principles which, for convenience sake, we call Egyptian, and which the commonest sense recognises as the sole principles which are apt to granitic architecture, enables us to judge of the embankment in its broadest features and chief lines of composition. In these, the same lack of repose, of magnitude of elements, and of gravity, appear, as in the details to which we have referred. A wall of stone banding a river, and running in so long a sweep as any of the vistas of the embankment affords, would seem to require that the horizontal elements of its nature should be left to express themselves grandly, as they would surely do if left alone, or with as little interference as convenience might admit. The artistic eye recognises in a moment the superiority of the solid parts of the parapet in this work over those where the before-named balusters have been admitted. In the former, the work is at its gravest and soberest. The treatment which has been vouchsafed there is obviously the most apt, and so much of repose and horizontality, so much of largeness of features as the designer permitted, are to be found in the plainer lines of the enormous wall. Here the principles to which we have referred are educed by comparison of parts.

That simplicity which we desire, that breadth which is proper to structures of this class, and still more in works of this material, needed emphasis to be given only to parts which are serviceable—*e.g.*, the landing-places—and of obvious necessity. Except for these, the desirable simplicity and breadth should have been unbroken. There should have been few buttresses rising from the water, and measuring the wall in trivial spacings. The piers on the parapet, even if it had been solid throughout, should have been few and far apart. There should have been no balustrades; and if the solid parapet received mouldings at all, they should have been such as a bold, deeply-hollowed scotia would supply if incised in one long line from end to end of the wall. Either such an ornament as this, or its equivalent, a great torus, or roll moulding, would, if well studied in their contours, have sufficed to give grandeur and monumental dignity, where all sandstone mouldings are strikingly unapt and wastefully costly. We shudder to think of the price of granite balusters, which, if they had been carried along the whole parapet of this vast river-wall, would have been something prodigious. Putting cost aside, and assuming—which is gratuitous—that an open parapet was a necessity, the worst, commonest, and ugliest sort of that thing is the balu-traded parapet. The order of balustrading which has been adopted here has not even the merit of resembling that which already exists on Somerset House and Waterloo Bridge.

BISHOP PERCY'S BIRTHPLACE.

THE birthplace of Bishop Percy, and the residence of his grocer-father and grocer-grandfather, at Bridgnorth, has been restored by a member of the trade. It is situated, says *The Grocer*, in a street called the Cartway, and is the only vestige of the old town that remains from the memorable fire that resulted from the siege of Bridgnorth Castle by the army of Oliver Cromwell. It is of picturesque appearance, having five pointed gables, and constructed of solid beams of oak, and partly of masonry, similar in character, but far more beautiful, than Shakspeare's birthplace at Stratford. The apartments are of great altitude, being between ten and twelve feet high, and in its day it must have been considered a mansion of some importance, although until recently falling into a sadly dilapidated state. About twelve months since it was purchased by Mr. Benjamin Allen, grocer, of Camden-street, Birmingham, a gentleman of antiquarian pursuits, and a native of Bridgnorth, who has effectually and judiciously restored it. He felt that in restoring the house he would be paying a tribute to the memory of the author of "The Reliques of Ancient English Poetry," and the only literary man born in Bridgnorth. In one apartment of the house is a stone, on which the following inscription is cut in relief:—"Except the Lord Bvild the OWSE The Labovrers thereof evail not. Erected by R. For, 1580." Mr. Austin has placed an inscription on the beam over the first-floor windows (in Elizabethan characters), "The Old House, A.D. 1580;" and on the beam over the shop and house-place, "Bishop Percy born here, 1727." The shop is of very large dimensions, being 15ft. by 18ft., and it has been, till within two years, always connected with the grocery trade. It is now an ironfounder's mart.

THE WELSH SLATE TRADE.

THE difficulty experienced by consumers in obtaining the execution, within a reasonable time, of their orders for slates has long been a subject of remark, yet it is acknowledged that at many quarries certain descriptions of slate remain for months unsold (owing to the desire to execute some particular order) which could be readily brought into the market and sold at a profit. This arises from the impossibility of producing without waste slate, except by making whatever size the blocks will cut into, loss at all times attending the use of blocks of larger size than that absolutely necessary for the making of the slate required. As the sizes, therefore, of slate manufactured at every quarry entirely depend upon the nature of the blocks quarried, and as it is impossible to control the size of the blocks, so it is equally impossible to manufacture slates of the size immediately required by the consumers: this obliges quarry owners to hold their make of slate for months while they accumulate a sufficient quantity of each size and quality (about sixty classes) to execute their orders; and, as the blocks when quarried must be at once riven into the slate they are fit for, or would otherwise not rive at all, this is often the work of from six to twelve months, during which time they have to pay their wages and many other expenses in cash.

To effect a sale monthly many of the quarry owners have, says the *Mining Journal*, expressed their willingness to sell to a company (as middleman or factor) all their monthly make at a very large discount off the tariff prices, as the monthly realisation of their entire stock will enable them to extend their quarries and produce a larger supply, which would be of enormous advantage to themselves and a great boon to the public, the demand for slate being so greatly in excess of the quantity the quarry owners can produce, and which has been the cause of raising the prices of slates steadily for the last ten years, during which period they have advanced 30 per cent. The object of the company will be to bring the entire make of all the quarry owners doing business with them into their one depôt at Bangor, and there to sort them ready for delivery to the consumers. Supposing, therefore, only twelve quarries were delivering, the accumulation of slates of any particular size would it may be assumed, be twelve times as rapid at the depôt as at any individual quarry, so that orders which given to a single quarry could not be executed in less than a year could be executed by the company in a month. There are about forty distinct quarries from whom the company could buy slates; but take only half of them to begin with, that half would each give on an average 250 tons of slate per month. The average price from the published tariff is about 45s per ton. The company's depôt at the railway station, Bangor, is exactly in the centre of the two largest slate quarries in the world, and also of the numerous other quarries which constitute Bangor the slate market of the kingdom and ever must it is thought keep it so. Customers and stock are

there face to face; there is perfect railway communication with every district in the kingdom, and orders for slate can be executed immediately, while any individual quarry would require many months to accumulate them. It appears, from the experience of the manager of the largest quarry in the world (near Bangor) that the promptitude with which payments are made in the slate trade is remarkable; in their enormous transactions (turning over nearly £500,000 a year) they have not, during the last three years, lost a single penny by bad debts, and that in the same concern during the last thirty years a fraction of one penny in the pound has covered all the bad debts made.

TECHNICAL EDUCATION IN THE POTTERIES.

IN connection with the Art, Scientific, and Literary Institute at Burslem, the birthplace of Josiah Wedgwood, in course of erection as a memorial of the great potter, two meetings were held on Friday last, attended by Mr. C. B. Adderley, M.P., Mr. Beresford Hope, M.P., Mr. G. Melly, M.P., and other gentlemen. At the first meeting Mr. Hope, who originated the idea of making the building a monument of the manufacture which Wedgwood made famous, as well as a memorial to the "Father of the Potteries," described the new building (the first in England in the construction of which ceramics enter so largely) as a remarkably successful experiment in ceramic architecture, and as a graceful specimen of its own graceful style. Mr. Melly presided over the evening meeting, and much of his opening address was devoted to technical education, which, he said, was now a vital necessity to England if she wished to retain any of her superiority in trade. In Prussia there were 11,000 pupils receiving instruction in science and art. In Sweden there was a constant increase in the number of pupils, and the manufacturers of the window frames and doors, whose arrival in England had raised the cry for technical education, were pressing their Parliament year by year for increased facilities for carrying on national art schools. In Norway there had been no very great increase in technical education, though the manufacturers were in favour of its extension. In America, where they would expect technical education to have taken a firmer root than even in England or Germany, the State had confined itself to a grant of 195,000 acres of land for the purposes of technical education. Comparing England with the countries named, said Mr. Melly, we are bound to admit that though in the matter of art England lagged not far behind, in respect to technical education we are a long way behind other nations. Mr. Beresford Hope then delivered an address on art education, and the application of art to every-day life; and Mr. J. C. Buckmaster followed with an able and practical speech on technical education. A resolution was passed pledging the meeting to support the Wedgwood Institute, and to establish technical education classes in connection with it. The memorial building will be formally opened next Easter with an art exhibition. The cost of the building will be £9,000.

QUADRATURE OF THE CIRCLE.

IN former days mathematicians devoted much time and labour to the question of determining the ratio of the diameter of the circle to its circumference. Archimedes found that it was nearly as 7 to 22, and this ancient solution is still very useful for ordinary purposes. Later researches brought it at length to such a point of precision that it would be idle to seek any further, the ratio being as a unit to 3·1415926, with a continuation of 120 decimals more. It follows, then, that any attempt to make the diameter go exactly into the length of the circumference, or to represent their ratio by an exact fraction, is simply ridiculous. As such a solution, were it possible, would enable us to make a square containing the exact surface of a circle, this problem is commonly known under the name of quadrature of the circle. At last week's sitting of the Academy of Sciences, says *Galignani*, the perpetual secretary announced that a newspaper had recently revived an old story to the effect that the Academy was in possession of a considerable sum bequeathed to it as a reward for any person who might discover the quadrature of the circle. He, therefore, suggested the propriety of again publishing the decision the Academy came to in 1775, of never more devoting the slightest attention to the solutions that might be sent in of the following problems:—The duplication of the cube, the trisection of the angle, perpetual motion by means of a machine, and the quadrature of the circle. It justified this course as regards the latter, by remarking that many weak-minded persons, utterly ignorant of mathematics, and labouring under the impression that large sums were ready to be handed over to them in case they succeeded in solving that problem, devoted their time to it, utterly neglecting their regular business and the interest of their families, and even occasionally losing their reason by following such a vain pursuit. M. Bertrand stated that the belief in the promise of large prizes by the Academy for the solution in question had been propagated by very serious works. The "Biographie Générale," for instance, had stated that M. Rouille de Meslay had left the Academy 120,000f. for that purpose. He stated that in the eighteenth century an inventor of the quadrature actually summoned D'Alembert before the Parliament in order to recover that sum.

GENERAL BUILDERS' ASSOCIATION.

THE following circular has been issued to all the Local Associations of the General Builders' Association on the proposed notices to be given for amended trade rules:—

"You are aware that at the Annual Meeting of the Association, held at Liverpool on the 8th inst., it was decided that each Local Association, in whose district the trade rules did not provide for payment by the hour and the formation of arbitration and conciliation courts for the settlement of trade rules and disputes, or contained provisions against the use of quarry-worked stone, or machinery, should give the requisite notices for the adoption on the 1st of May of new rules. A special committee was appointed for making the necessary arrangements for giving these notices. At a meeting of that committee, held at Bradford, on Wednesday, the 21st. inst., I was instructed to send you the following suggestions:—

"The Committee think that it is very desirable that the notices should be as similar and as simultaneous as possible. They, therefore, recommend that you should immediately call your Association together, and get authority to send notice to the workmen of those branch trades that require it, to the following effect—of course altering it in any way you may require:—

"Name of Town.....
"Date .....
"To the Operative.....

"We, the Master Builders employing Operative.....in.....do hereby give you notice that we require the following alterations in the Trade Rules now in force in this District:—

[Where the hour system is in force this ¶1. paragraph is to be omitted. Where quarter time is not mentioned in the rules, strike out "and quarter time."]

"¶ I.—The rules relating to the reckoning of time, and quarter time, and the payment of wages, are to be abrogated and rescinded, and in lieu thereof the following is to be the rule:—

"RATES OF WAGES.

"That the following shall be the ordinary rate of wages for skilled operatives. Superior and inferior workmen to be rated by special agreement.

[* Alter this word to suit each branch trade to whom notice is sent.]

"* Bricklayers, the men who have hitherto been paid per week, shall be paid per hour.

[Where no such rule or custom exists, this II. paragraph is to be omitted.]

"¶ II.—Any rule or custom forbidding or interfering with the employment or use of machinery or machine-worked materials, is to be abrogated and entirely done away with.

[To be sent only to the operative stone masons.]

"¶ III.—Any rule or custom forbidding or interfering with the introduction or use of stone worked at the quarry, or anywhere else than the place where it is to be used, is to be abolished and done away with.

[Where Arbitration and Conciliation Courts are already established, this may be omitted.]

"¶ IV.—That all trade rules, disputes, demands, and differences shall be settled for the future by conciliation or arbitration, and proper courts shall be constituted for the purpose.

"And we hereby further give you notice that we are prepared at any time, upon six days' notice from you, to meet you and publicly severally appoint our arbitrators, and mutually select the umpire. And we are willing to leave to the decision of this Arbitration Court, thus appointed, not only all future settlement of trade rules and disputes, demands, and differences, but also the settlement of all matters contained in this notice, *and in the notice received from you.*

[If no notice has been received from the men, leave out the words in italics.]

"And we hereby further give you notice that we require the alterations contained in this notice to come into force on the 1st day of May, 1869, or on such other day as is mentioned in the existing rules as the day upon which new or altered rules shall come into force.

"Signed, on behalf of the Master Builders. .....

"The marginal notes will give you directions how to vary the form of notice to suit the circumstances of your locality and the various branch trades. In case you have no rules existing, it is desirable that you should give a notice for rules, and include in them the rules above given.

"I must call your particular attention to the fact that if your existing rules require you to give six months' notice, you will have to do so on or before the 31st of this month, to secure the adoption of the new rules by the 1st of May next year. In some cases notice has to be given still earlier. There is, therefore, now no time to be lost.

"The Committee think that the notices had better not only be sent to the various recognised Societies in your district, but also that they should be printed and posted up in the yards and workshops of each master in the locality. You had better also send a copy to each architect in the town.

"When you have given the notices, will you be so good as to send me a copy of each of them? I have sent a copy of this Circular to the Chairman of your Association, and beg that you will see him as soon as possible. I have also sent one to each member of the General Committee resident in your district. A. MAULT, *Secretary.*

ROTHERHITHE SICK ASYLUM COMPETITION.

FOR some days past the drawings for this competition have been on view at the Vestry Hall, Russell-street, Bermondsey. The accommodation to be provided is for 500 patients. The buildings are to be on the pavilion principle, so planned as to be easily capable of extension, and they will be in blocks of not more than three stories. There were five competitors, namely:—

Name.	Votes.	Estimate.	Motto.
George Legg.....	1	£35,000	Humanity.
George Elkington	0	32,000	Hope on Work on.
Ernest Turner...	9	29,000	Serio.
C. H. Cooke.....	0	28,000	Faith.
Giles and Biven	3	27,000	Experience.

The design of Mr. Ernest Turner, of 44, Bedford-row, was selected. Estimated cost, £29,000. The only exception to the conduct of the competition is that the instructions *ask for estimates*, and fix the remuneration at £900 inclusive, thus ignoring the established principle of payment by commission on cost.

Passengers in St. James's Park may have lately observed some workmen employed in the demolition of an ugly-looking chapel not far from the India Office. This edifice formed part of a mansion, now the office of the London recruiting district, which formerly was the residence of the notorious Judge Jeffreys. The entrance of the mansion is from Duke-street; but as a mark of favour, King James II. granted Jeffreys permission to throw out a flight of stone steps leading to the park; these still remain and distinguish the house from the others in the same row.

HOW TO ARRANGE AN ORGAN.

IT very frequently happens that when great fault is found with anything, especially in matters artistic, and however fairly it may all be put, it is but too common to reply to the fault-finder, "Why do you not suggest something better." This is rather unfair, for a man may be a very able critic and apt at finding out the faults of a picture or a building without being a painter or an architect, or able himself to paint a picture or design a building. But I wish to say in this place especially, once for all, that I do not attempt criticism, *per se*, for love of it, or for care about it, but with the simple object of putting some things, as far as I can, a little straight. In the present case no one will dispute the fact of the position of the organs of Westminster Abbey and St. Paul's—to say nothing at present of the Temple Church—being at least doubtful, awkward architecturally, and destructive musically, and it would seem to be enough to point this out; but I hope and wish to do more than this, viz., to show *how* things may be bettered, and what good and sufficient reasons there are for making the attempt. To find fault is not to make perfect, but it is the first step to it. With this purpose, therefore, in view, we propose to hint at a somewhat new mode of arranging the organ at Westminster Abbey on the present organ screen; and to endeavour to show how very much must be gained by such a "restoration," both architecturally and musically, and also, and this is a pressing consideration, how much *easier* and satisfactory it would prove to the *performer*. It may be observed in the first place, confining ourselves to the Westminster organ, that the screen on which it stands was left in its present place and saved from destruction solely from the fact of the said screen being the work of a living architect—"out of delicacy to Mr. Blore," the then cathedral surveyor, it was said, "we preserve the screen." What would have happened had the screen been an old one, or a Renaissance work, I do not presume to say; in all human probability it would have been destroyed and the whole abbey "opened out," everything going before this one purpose, and the very idea on which the Abbey was built destroyed and lost. One cannot help wondering more and more that anything is left in this place, and here I cannot but call the reader's attention to the notice in a recent number of this journal, reprinted from the *Ecclesiologist*, where this now fashionable mode of architectural destruction—the opening out mania—is so emphatically and usefully condemned, and it is sincerely to be hoped that it will be carefully read and attended to by those who have it in their power to do so much good and so much *evil* while they hold our cathedrals in their custody. Nothing can surpass the dulness of the new work in the Abbey, the two iron screens across the transepts, and the smaller screen next to the sedilia, or "Sebert's tomb," as it is called in verger phraseology. So it is a simple bit of sheer luck that this organ screen is left, and we ought to be right thankful for it. Thus is Westminster Abbey theoretically and theologically complete, *i.e.*, so far as the mere idea of the place, as designed by the builders of it, goes, and there is, while this endures, ground to stand on and a certain and fixed point of departure—this enclosed sanctuary space, however used or misused. That the screen forming one end of it is a good place for the organ, whatever the date of its introduction, was at one time at least generally admitted, is proved by its almost universal acceptance in every cathedral in England, and by the magnificent results found to flow from it; and the sole question then and now is, *how* to arrange the organ or organs in the best way, and *where* the organist should be placed? In St. Paul's the whole of the sound effect produced was natural and proper to the building, but in Westminster this was not so. Nearly everything depended on the position of the several parts of the organ and on the skill and taste of the organist. I think the organ in Westminster Abbey should be arranged thus:—Beginning with the choir organ, used for accompanying quietly the singers—sixteen boys and twelve men—few enough for a large cathedral; and what on earth they, the cathedral magnates, would ever do without the boys it would puzzle a musical magician to say, for they and the organ do pretty near all the work. This organ should, I think, stand in the *centre* of the loft, so as to be surrounded by the larger organs, and thus the sound from its pipes be softened, for when the voices are good and the music very good too, the gentlest instrumental accompaniment is enough, indeed, a note *here and there* seems almost enough. The "swell" is, as all know, occasionally used for this purpose, and its effect, when judiciously employed, would seem to be the perfection of music, as far as the material means of producing it are concerned. This "swell" organ occupies some considerable space, and should stand on the west side of the screen, with the front of it facing the west window, the louvres of it opening towards the west, so as to send the sound, when the louvres are open, into the nave; for it is here that the fine musical effect of which I have spoken as peculiar to Westminster Abbey seems to me to have found its origin—*i.e.*, the sound gradually increasing as the louvres opened, rolling or swelling into the nave, and from thence by reflexion back again, so that the beauty of it, though so far artificial, rivalled that in St. Paul's, where the *building* itself did all the work. It may here be observed that every large open structure like St. Paul's or York Minster, or Westminster, has an echo, or sound, or note peculiar to itself, and of which it seems impossible to explain the exact cause, the elements of it being so complicated. But whatever be the cause the results are most glorious and striking, and I hesitate not to say that no Handel chorus has or can be ever heard truly out of a *cathedral* or other building wherein it exists; indeed, I lack words to do justice to it—certainly not to those who have not already noticed it. The louvres thus facing the west wall should not, as I think, be hidden by sham pipes, but should show themselves honestly, and if gilt would be as "ornamental" as the mere pipes, there would too be no obstruction to the passage of the sound from the swell box into the nave. I do not well know how it would act, but would it not be an improvement to *curve* the back of the swell box—say, about three-quarters of a semicircle, and thus to concentrate the sound before it finally leaves it? Opposite to this, and facing the sanctuary or east end of the church, would be the great organ, as it is called, with all the pipes in the front of it, or facing the east, speaking pipes, and plainly gilt, if the natural colour of the metal be hidden at all, for nothing can well be worse than badly designed and badly executed Gothic diaper. Thus far the old arrangement would be retained, the swell and great organs being in their old and time-honoured places. On the south end of the screen, and partially at least between these two organs, would come the pedal organ with the large wooden pipes, which of course would and ought to stand *upright*, so that their sound would rise up into the roof, and not, as it does now, right up against a dead wall, thus adding clearness and energy to the sound from them. These pipes ought to be allowed to show themselves as pipes, and not to be hidden by false pipes, or by being boarded up as they so often are. If the plain wood be thought unsightly then gilding them would be best, as was suggested with the louvre boards of the swell organ. I am merely suggesting, as I cannot give *accurate* dimensions, and a plan of the organ would necessitate one of the screen as well, and also the space taken up by the new trumpet stops, &c. These stops, almost forming a new organ, would occupy the north side of the organ, so that I suppose the whole instrument would form a square, or very nearly one. Thus the organ, though made up of many parts and sections, would form, as it should do, one complete instrument, all visible at a glance, and the whole of the parts of it sounding as one—a vital and essential point *when the full organ is at work*. It remains to determine the position of the performer. As is well known, it is generally in front of the organ, facing it, so that the organist, on whom so much depends, has the congregation and the singers behind him, and nothing would seem to be more awkward and inconvenient. This was the arrangement before this organ was altered, as it was at St. Paul's, and is so still. York Minster, the Temple Church, and St. Sepulchre's are all so arranged, and it has doubtless its advantages, best known to the organists themselves; but I would suggest that a better plan would be to place the organist on the north side of the instrument, so that the singers and congregation may be on his left hand, thus giving him the power of being able at a glance to see them, for there is, and must be, an advantage in *seeing* those whom he accompanies and leads; he still having the whole of the instrument before him, and not, as now, sitting in the *middle* of it, with one half of it behind him. A great deal more might be added to this, but it would lead us direct into organ playing, a wide and ever vexed question, unsuitable perhaps to these pages; but I may be permitted to add that while some most notable players accompany a psalm chant (to give one example) on almost a full organ, as the late Dr. Camidge, of York, did, as does Mr. Cooper, of St. Sepulchre's, Mr. Turle is content simply to lead and help the singers, sometimes with barely audible impressive notes—surely the perfection of "chant playing." I know nothing that is done in music comparable to this for modesty, inventiveness, and perfect finish, and it now serves only to perpetually remind us of our infinite loss when the material instrument on which it was so perfectly and wonderfully executed was so thoughtlessly and ignorantly and stupidly destroyed.

C. BRUCE ALLEN.

DETAILS OF CARVED OAK CABINET.

ONE of our principal engravings this week represents quarter-size details of the iron mounts, &c., of the carved oak cabinet given in the BUILDING NEWS, October 2. 1, 3, and 6 represent angle strap, locking plate with drop handle, and portion of the hinge. The roses, boldly convexed in the centre with a telling incision across at the top, which terminate the ties and hinges, are very effectively studded over the surface of the cupboard front, whilst their stems are bent in a very free and flowing manner. The foliage on the locking plate is exceedingly vigorous, and with the hollow drop handle and its washer is a very masterly piece of workmanship.

The woodwork, which for want of a better term we must call "carved," is grounded out of the flat. Nos. 2 and 4 are examples, and retain a curious feature peculiar to the decadence of mediæval art, viz., the somewhat erratic-looking curves incised on the surface of the larger leaves, evidently an attempt to depict in forced light and shade the raised mid rib of previous centuries, which in time flattened into the one-sided, crocketwise form so common to our own perpendicular work. Such landmarks as these will often go far to decide sixteenth and seventeenth century carvings, fragments of this date, especially in stonework, not being always easily distinguishable from Norman work. No. 5 is a portion of the diaper to doors of cabinet, half full size. The margin of the pattern is very thoughtful in design, and, trefoiled forms being unusual at the period, is rather uncommon. It is executed in black oak, and very delicately wrought, when compared with the rest of the woodwork. O. W. D.

The second annual dinner of the Liverpool Master Builders' Association took place on Tuesday evening, Mr. John Jones, the president, occupying the chair.

DETAILS OF CARVED OAK CABINET. GERMAN 16TH CENTY WORK.

THE SWEDISH AND NORWEGIAN TIMBER SUPPLY.

IF our statesmen have done wisely in making inquisition into the supply of coal in this country (says Mr. Andrew Murray, F.L.S., writing in *The Farmer*), and the length of time it is likely to last at the present rate of consumption, similar inquiries into the amount and probable duration of their supply of wood would seem to be not less called for on the part of the Governments of Sweden and Norway. Those who have not looked into the subject have little idea of the rate at which this vital product is disappearing from the Scandinavian hills. There are various protective laws, but they are, as Mr. Murray shows in detail, inoperative, and there is no practical check on the diswooding of the country, which may not be said to have really commenced. English capitalists and English sportsmen have begun to purchase estates and farms there. English timber merchants have begun to take leases of great tracts, for the very purpose of cutting down the timber, and their interest, of course, extends no further than the duration of their lease. Various symptoms of the progress of the dreaded calamity may be pointed to. It was stated in the Swedish catalogue of the 1862 Exhibition that originally shingles for roofing houses there were made of fir (*Abies excelsa*), but the scarcity of fir had now caused the wood of *Pinus sylvestris* to be used instead. Our consul at Christiania, in 1860, reported that great complaints had lately been raised against the injudicious system followed of late years of cutting down indiscriminately young trees for conversion into pit props for the northern ports. To such an extent had the felling of small timber been carried that the State had deemed it expedient to nominate a commission for the purpose of reporting upon the present condition of the forests of the country, and their capability to sustain their present annual amount of export. Considerable State forest lands have been brought under the control of public inspectors, with a view to their better management. Our consul at Götha, writing in 1863, stated that the supplies of wood continue to exhibit a decrease of heavy sizes, and prove the steady progress towards a gradual exhaustion of the forests which supply the saw-mills in that part of the country.

The timber used in building in Norway is also smaller than it was wont to be in old times. Mr. Laing, in his "Residence in Norway," says :—

> In building houses in Norway, timber is used of a size far exceeding the dimensions we generally suppose its trees to attain. There is a log in this old house which is 3ft. on each square side, and retains that size for at least 25ft. of length. In all the houses, especially those of very old date, the logs are as large as the Memel or American timbers usually brought to England. I understand that the impediments in the rivers prevent the floating down of such lengths of great timber to the coast.

But nothing speaks so strongly as statistics, which show a very large increase in the exportations within a very few years. In 1853, Norway exported 248,402 lasts (two tons) of timber, and in 1864 she sent out 403,566 lasts. In 1858 she also exported 721,024 loads (50 cubic feet), and in 1863, 950,000 loads. Sweden, in 1851, exported 865,533 dozen deals and planks of fir and pine, and in 1863, 1,747,950 dozen. The same country in the former year sent 429,600 (in number) beams, rafters, masts, and spars, and in the latter, 883,397. The same rate of increase is visible in the imports into the United Kingdom from Sweden and Norway, for in 1854 there were imported from those countries 186,134 loads of timber not sawn or split, and in 1865, 336,457 loads ; and in the first six months of 1866, 196,794 loads were imported. One explanation of this large increase is due to the alteration on timber duties, so that Norway and Sweden have been enabled to encroach on the Canadian trade. Sweden now falls little short of that colony in her shipments of timber into England, and the removal of the duties may, instead of an evil, prove a blessing to Canada by restraining the excessive denudation of timber which would otherwise have taken place. In 1864 the importations into England were from Canada, 2,938,300 standard ; from Sweden, 2,644,500 ; from Russia, 1,904,900 ; from Norway, 1,504,500 ; and from other countries, 123,800 ; a total of 9,120,000. Thus Sweden with Norway supplies to her over four-ninths of her deals, and over one-half more than her own equally endowed province of Canada.

A Swedish correspondent thinks that the supply from Sweden reached a maximum in 1863 and 1864 (his latest dates), but statistics scarcely support this view, the export of fir from both Sweden and Norway in 1865 being 336,457 while that in the first half of the year 1866 was 196,794, or actually at the rate of one-eighth higher ; but even were it otherwise there would be little consolation for the Swedes in that, unless it was due to their own self-control or prospective regulations, and not (which it really was) a diminished demand from this country. On this point the same correspondent writes :—

> Till 1863 the export of wooden wares from Sweden was rising, as well of beams as of planks and boards. For the last years I have no reports. I scarcely believe that there has been any considerable decrease. However, the export of wooden wares may, at least for a period, have reached a maximum, and then be forced to diminish, for already a couple of years ago, the principal foreign import harbours for wooden wares were filled, and it is a known thing that there are many magazines of sawn dressed timber at the harbours in Norrland which they have not been able to sell.

It is difficult to avoid the conclusion, from the largeness of the quantity thus supplied, its rapid increase, and the fact that the dimensions of the timber supplied are gradually decreasing, that Sweden has been encroaching on the capital stock of her timber and not living upon its interest. It would seem a politic proceeding on our part to consider how this will hereafter affect ourselves, and whether it would not be wise to provide against the contingent dearth of timber to which our children may be exposed by planting more ourselves at home.

Building Intelligence.

CHURCHES AND CHAPELS.

On Thursday week the foundation stone of a new district church was laid at Monkwearmouth. The church will consist of nave, north and south aisles, chancel, vestry, organ chamber, and porch, and provision will be made for the erection of a lofty tower and spire at the south-west angle of the nave. The style will be the Early or First Pointed style of Gothic architecture, with a good deal of the early French character about it. Accommodation is to be provided for upwards of 600 adults. The church will be surrounded by a low wall and ornamental iron railing. The contract for the church is £3,600, and the total cost will amount to about £4,000, exclusive of the tower and spire, which will cost £700 or £800 more. The building is designed by J. P. Pritchett, Esq., F.R.S., B.A., of Darlington. The contractor for the whole is Mr. Walter Scott, of Sunderland.

A new Anglican Church, dedicated to St. Patrick, has been consecrated by the Lord Primate, at Carrickmacross, Co. Monaghan, Ireland. The building is in the Early Irish style, built of grouse stone and free stone, found upon the estate ; a plain nave and spacious apsidal chancel, the latter both pointed and roofed with stone, and surmounted by the Irish cross. The interior of the apse is lined with polished alabaster and Minton's tiling ; the pulpit and font are principally of Caen stone and alabaster, and the chancel is of green Galway marble. The windows are by Clayton and Bell, of London.

The church of SS. Philip and James, Milton, near Hanley, was reopened on Tuesday week, after restoration. A nave and aisle have been added to the former chapel, which now serves as a chancel. The total cost of the work was £862.

Eccleshall parish church, which was lately restored by Mr. Street at a cost of £7,500, as a memorial to the late Bishop Lonsdale, caught fire on Sunday morning. The north aisle, the tower, and the vestry, as well as the woodwork, have been very much injured, and the damage done is said to be to the amount of between £1,000 and £2,000. The fire began in a beam built into a chimney of the warming apparatus, which was only lighted for the first time on Saturday.

St. Michael's Church, Sittingbourne, has been restored by Mr. Vaughan, of Maidstone. In scraping the walls of the interior of the north aisle an amateur came upon the framework of a doorway to the staircase leading to an ancient rood loft stretching across the church. The figure-heads of Edward I. and his queen, Eleanor of Castile, may be made out as corbel heads of the doorway of the porch.

Archbishop Manning laid the first stone on Monday of a Roman Catholic Church at West Drayton, in West Middlesex. The church is to be English Gothic, in the style of the fourteenth century, and will be about 80ft. long by 15ft. The architects are Messrs. Wilson and Nicholl, and the builders Messrs. Fassnidge, of Uxbridge.

All Saints' Church, Little Munden, Herts, was reopened on Thursday, the 8th inst., after undergoing a thorough restoration (with the exception of the tower). The building consisted of nave, chancel, chapel, north aisle, north and south porches, and square tower with a low spire, to which have been added a vestry on the south side of chancel and a vault for hot water apparatus at west end of aisle. The church is built throughout of flint stones, which have been refaced and pointed, with Bath stone dressings and tiled roof. The old ceilings of the nave and chapel have been taken down and the roof opened to the ridge, the oak joists, &c., repaired and oiled and plastered between. Unfortunately the interior, looking westward, is spoilt by an abomination in the shape of a raised pew, or, more properly speaking, box, approached by a semicircular staircase, which blocks up the upper half of the west door. Strongly as it is condemned, nothing appears to induce the owner to allow of its removal. The whole of the works have been executed at a cost of about £2,000, by Mr. T. Ginn, of Puckeridge, under the superintendence of Messrs. Godwin, architects. Since writing the above, the order has been given to restore the tower also.

A memorial to deceased communicants has just been completed in Trinity Church, Hempton, Norfolk, in the form of a reredos extending the whole width of the chancel. The side spaces are filled in with encaustic tiles, and the central space above the retable shows two panels ornamented with Minton's majolica tiles, supporting the raised centre of alabaster, on which is a cross of green and red marbles on a background of alabaster (executed by Messrs. Field, of Parliament-street, Westminster). The retable has an incised text in early fourteenth century letters, red and black ; and the memorial inscription is placed behind the altar. The design was supplied and the work superintended by Mr. C. J. Moxon, A.R.I.B.A., of Gower-street, London.

The cemetery chapels and lodge, Thornaby, South Stockton-on-Tees, have just been completed. The materials used are red pressed bricks, with Dunhouse stone dressings and slated roofs ; the glazing is of Hartley's tinted cathedral glass ; the floors are laid with black and red tiles ; the roof timbers, as well as all other woodwork, is stained and varnished. The total cost of the whole, including two chapels, lodge, entrance gates, piers, railing, &c., is £816. The design is that of Mr. G. G. Hoskins, architect, of Darlington and Sunderland. Mr. Leonard Bourn, of Stockton-on-Tees, was the contractor.

On Saturday week the new church of St. John, Accrington, was opened. It consists of nave 92ft. by 40ft., chancel, side aisle, two transepts, porch, and baptistery in the lower part of tower. The exterior is plain and of simple detail. Mr. H. Macauley, of Accrington, is the architect.

A new Wesleyan Chapel was opened at St. Dominick, Cornwall, on the 22nd inst. The building, which is designed to accommodate about 200 persons, is of Early Gothic character, with a somewhat continental boldness of treatment, and is constructed of local stone, with Polyphant stone dressings. The only carving introduced is in the caps of columns to the main entrance. The total cost of the erection was about £500, and it is intended to add a schoolroom at some future time. The contractors for the work were Messrs. Cousens and Poad, of St. Dominick ; and Mr. Henry H. Pearse, of Stonehouse, was the architect, under whose direction all the works were executed.

The new church for the parish of North Otterington, Yorkshire, was consecrated last week by the archbishop of the diocese. The designs for the building were supplied by Messrs. Atkinson, architects, York. It consists of a nave, chancel, vestry at the north-east porch at the south-west end, and bell turret at the west end. The style is Early English. The outer walls of the church are rough Bradford sets, with Osmotherley stone facings. The inner walls are lined with pressed red bricks varied with courses of black brick. The floors and reredos are laid with Maw's encaustic tiles. The cost of the building is £1,150.

The chancel of the church of Bowers Gifford, Essex, has been restored. The windows, which were of wood, have been replaced by stone ones, of the Tudor period: the high pews, whitewash, and plastered ceiling have been removed, and a panelled timber roof erected. The altar has been raised, and the floor paved with Minton's tiles; and the east window has been filled with stained glass by Messrs. Lavers and Barraud. This window was exhibited by the firm at the Paris Exhibition.

St. Michael's Church, Cornhill, which was restored and partly decorated during 1858-9-60, has been recently closed for cleansing, &c., and further decoration. The works now completed comprised colouring and ornamentation of the walls and windows of the tower, decoration of the reveals, columns, &c., of aisle windows, scroll enrichment to main shafts, new encaustic tiling and marble steps to chancel, complete restoration of the reredos, the introduction of a circular stained light in the ante-church, and decoration of window and wall. A new cloister, leading from St. Michael's-alley to the churchyard, has been erected in Portland and Caen stone, with red Mansfield shafts, having richly carved capitals. The organ has been restored, and electricity applied for playing from one side of the chancel to the other. The decorative work has been done by Messrs. Trollope, under the direction and superintendence of Mr. Hubert Williams, the architect to the parish, and his son, the assistant architect; and Messrs. Barnsley, of Draper's Hall and Birmingham, the cloister and other works; the organ by Messrs. Bryceson Brothers, under the direction of Mr. Limpus, the organist.

BUILDINGS.

On Monday morning the foundation stone of the new townhall at Manchester was laid by the Mayor. The new hall is erecting on a plot of ground comprising 8,000 square yards, and is bounded on three sides by three of the leading thoroughfares of the City—Albert-square, Princess-street, and Cooper-steet. It is to be built from designs by Mr. Alfred Waterhouse. It will be a magoificent Gothic structure, with principal façades (having a tower in the centre of each) to the three thoroughfares named. The principal and most ornamental façade will be that to Albert-square, which will have a frontage 310ft. long and a clock tower 260ft. high. The hall will contain about 250 rooms, and is estimated to cost (including purchases of ground and property for the site) upwards of half a million of money. The building was illustrated and fully described in the BUILDING NEWS of May 8, 1868.

Mr. C. W. Whitaker writes to say that the cost of the new hall to be built over the market at Exeter is £3,000, and not £5,500 as stated by us last week. He also says that his father has no connection with Tiverton, as stated by us, but is the consulting engineer and surveyor to the Local Board of Exeter.

At Wisbeach, Cambridgeshire, a long-felt want is being supplied—viz., a properly constructed cattle market. The whole of the works are being carried out under the superintendence of Mr. Charles Mumford, the borough engineer. The contractor is Mr. John Fast, of Melton Mowbray, who recently carried out the important cattle market works at Peterborough. The ironwork is from Messrs. Mellard and Southwell, of Rugeley, Staffordshire.

The new premises for the London and County Bank at Oxford are just completed. The style adopted is Tudor. The materials used have been the best white bricks of the neighbourhood for the several fronts, with Bath stone for all the stone details. The exterior is relieved by buttresses, projecting chimneys, and windows of varied design. The whole of the works, including the adjoining premises, will cost about £9,000; they have been executed in a most satisfactory manner by Messrs. Jones, from the designs of the architects, Messrs. Francis, of London.

A company is now being formed at Ramsgate having for its object the erection of large assembly rooms. The capital is £10,000, a large portion of which is already subscribed. Mr. Bridge, architect, has drawn up plans and specifications of the proposed buildings The grand hall will be 120ft. by 55ft. Tho decorations will be in the Italian style. The roof will be domical, devised as a shell, and the ceiling will be elliptical. There is to be a colonnade of shops on the ground floor.

The new courthouses at Falkirk were opened last week for public business. The style of architecture is Scotch Baronial, and the design is by Mr. Ford, a local architect. The cost of the buildiog has been about £8,000.

There have been recently erected at Harlow, Essex (says a local paper), by Mr. Selwin Ibbetson, M.P., several model cottages for agricultural labourers. Each cottage contains a living room and three bedrooms, with entrance porch, scullery, pantry, fuel store, and privy, and each dwelling is provided with a washing copper, a sink, and a fireclay oven from Devonshire. The living rooms have cottage ranges, and the bedrooms fire-lump cottage grates. The rain water from the roofs is collected in tanks for domestic use. The cottages are built with Cambridge bricks and covered with Huntiogdonshire tiles. The works have been carried out by Messrs. Bell and Son, builders, of Cambridge, from designs by Mr. Birch, architect, of London. We hear that Mr. Birch is erecting similar dwellings on an estate in Wiltshire belonging to Mr. R. P. Long, M P.

At Warnham, the beautiful seat of Charles Thomas Lucas, Esq., a racquet court has been erected, and it is said by a correspondent to be one of the most perfect buildings of the kind. The floor is laid with Pyrimont Seyssel Asphalte, which has been found at Aldershot and other places the best possible material on which the game can be played.

During the closing of the Junior United Service Club for annual repairs some important alterations have been executed under the direction of Mr. Wilson W. Phipson, C.E., for the improvement of the ventilation of the Club. A fan worked by a small gas engine now supplies the fresh air to the building, a new fresh air supply erected near Waterloo-place, and an entire rearrangement of the old air pipes and main channels to the different rooms constitute the most important features of Mr. Phipson's new arrangement; besides which, a more direct use of the existing extracting shaft has been effected, so that the coffee-room especially derives great advantage from the adoption of this plan.

The foundation stone of a new public bathhouse was laid at Staleybridge on Saturday. The estimated cost is between £4,000 and £5,000. Messrs. Paull and Robinson, of Manchester, are the architects.

TO CORRESPONDENTS.

NOTICE.—Cases for binding the BUILDING NEWS, Vol. XIV., are now ready, price 2s. each.

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

RECEIVED.—W. I. F.—I. P.—P. H.—E. and P.—R. C.—C. L. E.—I and Co.—I. M. S.—C. L. C.—G. P. M.—I. F.—I. and T. H.—G. B.—I. H.—"No one in particular."—I. R. A.—W. R.—H. C.—A. T.—I A. H.—I. A. D.—I. F.—I. C.—T. A.—C. J. P.—G. G. H.—O. W.

A SUBSCRIBER.—Write to secretary of Institute of Architects, 9, Conduit-street, and secretary of Institution of Civil Engineers, 25, Great George-street, Westminster.

Correspondence.

CITY IMPROVEMENTS.

To the Editor of the BUILDING NEWS.

SIR,—More than seven years have now passed since first we suggested, through the medium of your journal, a means for gradually effecting considerable improvements in the City of London, and almost without cost. During that time we have met with nothing to deny the feasibility of the plan, and, as very few things are adopted in this country without much trouble and repeated attempts from the promoter, we beg leave to renew now the proposition which we made in the BUILDING NEWS for April 19, 1861. In the course of the last forty years, or we might even say the last twenty years, millions of money sterling have been spent (irrespective of railways) in improving the streets of London, and rendering them better adapted for a doubled and quadrupled population. This outlay has naturally, and perhaps wisely, been made upon leading thoroughfares; and when the Thames Embankment is completed, the new street from the Bank to Blackfriars finished, and other works already in progress are ended, our metropolis will certainly begin to assume an appearance somewhat worthy of her prodigious size and wealth. But we have at once to consider what is to be done, after the few trunk lines of communication have thus already been opened, towards improving the great number of second-rate streets in the City, which are so highly inconvenient from their extreme narrowness. There is but a very limited benefit to traffic in opening out a half-dozen of principal roads if scores on scores of tributary streets are left in a chronic state of congestion, proving a daily nuisance and hindrance to myriads of the population. How miserable, for instance, is the condition, for vehicles, not merely of such respectable streets as Thames-street, Tower-street, Queen-street (Cheapside), and others, but of the host of minor lanes or streets where there is much traffic, but a painful difficulty of moving it. What a farce to see hours and half-hours wasted by carmen with waggons, carts, and horses, every day of the year, while tediously trying to crawl into or out of some narrow tortuous defile with a carriage-way perhaps 6ft. or 8ft. wide, and that blocked-up by some lounging waggoner who has gone for his pot of beer, or who surlily refuses to expedite his own movements or to shift his vehicle a few yards along the lane. The class of streets referred to are such as Old Change, Friday-street, Bread-street, Ironmonger-lane, Abchurch-lane, Pountney-lane, Botolph-lane, Silver-street, &c., streets where property is very valuable, occupied by most respectable firms, and where a considerable traffic is carried on; but which all suffer from this want of space. No doubt that the chief reason of this remaining *in statu quo* so long is the frightful expense which at the first view appears necessary to improve these lanes, together with the effects of long-seated use and custom, and, shall we say? the want of some thought and ingenuity directed towards improvements.

The suggestion by way of remedy which we made in 1861 was simply to prohibit any new buildings in streets of less than a certain width being increased in height above the old ones, unless they were set back a few feet in proportion from the original building line. Thus, in a lane 20ft. wide (and many of the City lanes are much less than that) no new house should be allowed to be carried to more than (say) 40ft. above the level of the pavement. But, if the owner would set it 5ft. further back, let him have liberty to carry it 10ft. higher, equal to another story. Where there is a will there is a way, and it is simply a case of drawing rules and embodying them in a supplementary building act. There are already a multitude of regulations in the building acts, and why should we hesitate to add one more which promises to be as soundly beneficial as any at present in force? We have restrained the liberty of the building subject in a hundred ways, and rightly so: why not in this? In Paris there are rules limiting the heights of buildings: why not in London? If something of this kind is not done we shall yearly get from bad to worse; population and traffic are still increasing, and as fast as old houses are pulled down others larger and higher are built on their sites, so that, instead of becoming more light, airy, and healthy, these City streets will gradually get more dark, stuffy, and unhealthy.

Very many of the old houses, though fronting on narrow streets, stand on plots of ground which are very deep, and, therefore, could be set back without injury to owner. Perhaps on a lane 15ft. wide, the plots are often found 60ft., 80ft., or even 100ft. deep. In a few years as the lane became widened the value of houses in it would increase, and the owner would eventually gain rather than lose by the first sacrifice of a few feet of area. If the depth did not admit of setting back, the proprietor must be content with keeping his building to the original height of the old one. By the time a few houses were set back in a street traffic would be greatly facilitated, as the recesses would allow of carts and waggons drawing into the "lay-byes," and giving space for others to pass freely. In process of time a whole street would thus be widened, and, which is an advantage impossible to exaggerate, without any

considerable tax upon the public. Nor yet surely can it be deemed a hardship upon a free holder to say "you shall not, in a densely packed city, rebuild your house any higher than it was before, unless it is set a little farther back." The principle we advocate is that a street only 25ft. wide, or 3ft. more than Queen-street, Cheapside, though confined enough, will yet accommodate a great amount of traffic, though certainly not enough for a main thoroughfare; it allows of two foot pavements of 5ft. each, and a carriageway of 15ft., which is quite sufficient for two waggons to pass. Hence it would not be necessary in most of the city lanes to make the builders set back more than a few feet on each side. However, the exact degree of height or of setting back is a matter of detail.

While writing we will add that when a new building act is brought in it should make provision for the extremely complicated and vexed question of ancient lights, which in the crowded part of an old city might well be put upon a different basis to suburban and rural laws. And we think some further requisition might well be made for back areas—the space of 100ft. superficial is quite too small for a large house. We will just invite consideration of these two points but will not diverge into an argument upon them at present.—We are, &c.,

H. and R. Powell.

IMPROVED CHINESE INK.

Sir,—I beg to call your attention to a new article, which I think will prove a boon to the architectural and mechanical draughtsman. It is simply a solution of redissolved Chinese ink, in which is a chemical mucilage which renders the ink insoluble after it has dried upon paper; consequently any colour may be passed repeatedly over it without blurring or washing it up. I have found in business the constant demand, Will it wash?—one stick of ink that washes only a little better than another being considered by draughtsmen as a prize of great value. I think it will also be an economical ink, as it will not need pouring out on the palette; the pen may be dipped in it after breathing in between the nibs, and only the quantity used that is required. It will not decompose, and if it thickens by exposure a little water may be added. Chinese ink being pure, finely divided carbon, it settles by its great specific gravity. The bottle will therefore require to be shaken before use, and this is the only trouble to be taken with it. There have been many solutions of Indian ink prepared by artists' colourmen, but these are only offered as a solution of Indian ink, and consequently wash up like it; they also decompose, as Indian ink will if kept in a solution by water only.—I am, &c.,

W. F. Stanley.

3 and 5, Great Turnstile, Holborn, London, October 27.

WALKS WESTWARD—STATION BUILDINGS.

Sir,—A subscriber who signs himself "Albert Edward" objects to the remarks under the heading of "Walks Westward," which appeared in the Building News of October 16th. He thinks I was "too hard upon the architecture of the stations," and seeks to transfer the blame, if any, from the engineers or architects to the too parsimonious shareholders, and asks how "under such circumstances can anyone employed as architect show his powers of design?" Now, he mistakes the whole tendency of my criticism, and estimates very humbly the resources of architecture and the ability of architects. Decent poverty, even in architecture, is always respectable, but poverty is not always decent. I never complain of the mere absence of ornament, but I do emphatically condemn attempts to adorn a manifestly poverty stricken building by ornament of any kind, and more particularly by such as is of a festive character, as vases wreathed with flowers and the like. I also condemn the glass porches and the columns which support them at the entrances to the several stations, because they are ugly when they might, for the same money, have been elegant. Again, I do not find fault with these stations because they are only one story in height, nor do I see any difficulty in treating such buildings, as "Albert Edward" seems to do. It is the shape of the structure and the uncouthness of the details that offend my eye. I apprehend that no architect had anything to do with the stations of the Metropolitan Extension, and it is no matter of surprise that engineers, however skilful, should fail in an art which demands fully as much study as their own. So long as they stick to their tunnelling and railway embankment making they do very well, but they do not shine in architectural works. I am not sure that bridges even are more in the province of the engineer than the architect, and I am perfectly sure that no architect could have designed such a bridge as disfigures the river at the Cannon street Station. In conclusion, let me say that I am always ready to maintain my remarks by special instance if they offend anyone, and that in this case I am obliged to "Albert Edward" for giving me this opportunity of justifying, and perhaps amending, my former criticism.—I am, &c.,

The Writer of the Article.

Sir,—The special pleading in the letter from your correspondent "Albert Edward" is no defence of the Metropolitan Railway stations, the designs of which were so justly stigmatised by you in a recent number. "Albert Edward" urges the parsimony of the engineers connected with that railway as a reason why the station buildings, which are still springing into existence, are so unsightly. But a barn may be constructed in good taste, and a fortune may be spent upon a palace which when finished shall be an eyesore. It all rests with the architect, and with him alone, to make these station buildings harmonise or otherwise. Numerous good examples of railway architecture prove the fallacy of "Albert Edward's" assertion that such designs cannot be dealt with tastefully; indeed, upon the Metropolitan line itself we have one example in which the most difficult situation is dealt with in the best manner. I refer to the Portland-road Station, which was designed apparently before the peculiar urn and tablet order came into vogue upon these works. And besides their positively unsightly appearance, these stations are marred by features which are outrages even upon rudimentary architecture. For example, note the preposterously elongated doors at the Bishop's-road and the keystones scattered so liberally around the Kensington Stations.—I am, &c., S. S.

Sir,—Though agreeing with your correspondent, "Albert Edward," as to the difficulty in carrying out any ornamental architecture in railway stations, I confess that it seems to me possible that variety even in ugliness might be introduced. The elaborate plaster vases and elongated keystones are the prevailing features in the exterior of the Metropolitan Railway stations, and I can scarcely imagine these to be the only means of ornament at the disposal of their architect. The stations on the Thames Embankment section of the Metropolitan District Railway are not yet commenced. Is it too late to hope for some novelty or elegance in their design?—I am, &c., G. T. J.

SOUTH KENSINGTON SKETCHING CLUB COMPETITION.

Sir,—Competitions at all times are more or less unsatisfactory, in consequence of what, in plain language, is favouritism; but at South Kensington—the last place where one would expect to find the disease—the malady has been witnessed in perfection. The members of the above club having forwarded their studies either of landscape or foreground, the decision to be made by the head masters, the result to be known on Thursday, the evening students, many of whom were subscribers, on arriving, are told the prizes have been awarded, the drawings taken down, and the prize works taken home without their having had the least sight of them. This looking very suspicious we demanded their being produced, and, to our great astonishment, find one a sketch, 6in. by 4in., of a cemetery monument—a figure in attitude of prayer, which the masters must have undoubtedly mistaken for an antique study, a branch which they always do their utmost to encourage, and consequently have thought fit to award it with the first prize. The second prize water-colour, and the same prize oil ditto, were the works of a master in training and the manager of the club—the drawings being one a sky study, the other of distant trees, &c., ¼-in. diam., possessing neither power nor feeling. Both works were carefully hidden from view and securely locked away. The first prize oil colour was indeed taken home, and has not yet been seen by the evening competitors. This, without doubt, was a study of a bunch of grapes under the name of foreground, perhaps with a dead robin to make up a group.

I may ask, Why were not these drawings exhibited at least three or four days, and even to the public on the following Saturday, arranged according to their merit. This would enable the students as well as outsiders to discover that which constitutes good landscape painting. Now, this being a landscape competition, and open only to subscribers, no one can but acknowledge that the whole has been carried out in a most unfair manner. But the masters themselves on becoming sensible of the injustice that had been done for that evening, instead of meeting the students, quietly sneaked away.—I am, &c., Justice.

CONCRETE HOUSES.

Sir,—Considerable notice having been lately taken in your columns of the accident to my house, I send you its history. A few months ago I was induced (from a perusal of *Tall's* pamphlet on his new patent machine, &c.), to erect a four-storied house in concrete. I, therefore, purchased the machine, at a cost of nearly £130, engaged as clerk of works a man from Tall's office, and solely on his strong recommendation (a man, it was said, used to the method and the material), and in all details followed the instructions given in the pamphlet. As to materials, I used Thames gravel and Little's cement, both of which received continuous praise, and the walls when at the third story were visited by the patentee and pronounced to be "very good." Notwithstanding, one wall suddenly collapsed, and the remainder proved so unsound that the whole had to be pulled down. The ruins throughout showed no "blocks" of concrete, but simply were as rubble out of a gravel pit. In addition, the patentee, who covenants in his pamphlet and on his bill of sale to take back the machine (when a house is built) at half price, takes advantage of the accident and leaves it on my hands. I tell the tale that others may profit thereby, and be doubly careful—as the invention is yet in its infancy—in their choice of machines, agents, and materials.—I am, &c.,

Geo. Larden, D.C.L.

Twickenham, October 28.

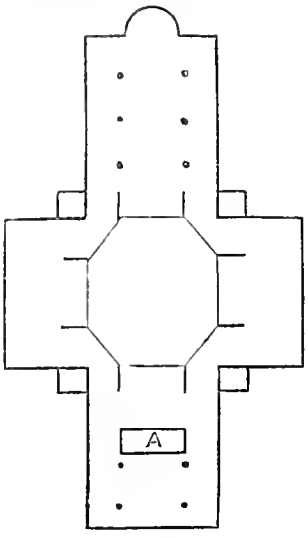
ORGANS AND ECHOES.

Sir,—In my former letter with reference to "C. B. A." and his predilections on the above subject, I did not write with your paper before me, and had the impression that it was the chorus, "The marvellous work," from the "Creation," which had been referred to by "C. B. A," and which ends in the manner I described. I find my memory had deceived me, and that it was "The Heavens are telling" that he referred to, which makes all the difference. Still I must maintain that the echo effect described by "C. B. A." is not essentially *music*, in the artistic sense of the word, and is, on the contrary, fatal to the effect of all but such simple music as consists in mere repetition of a few chords; and even in the simplest passages it is often injurious. For instance, I sat one day at the end of St. George's Hall, in Liverpool, when Mr. Best was playing the *chorale* from Mendelssohn's "Hymn of Praise," the melody of the chorale being given out, in very slow time, on the most powerful reed stops. The effect of the echo was such that at one point where the note C sharp is followed by D, the two notes were actually heard as if sounding together; the C sharp being prolonged by the echo through half the duration of the next note. Anyone with an ear will know what the effect of this must have been, and in this building all Bach's great fugues, when played on the full organ, are reduced by the echo to a most puzzling confusion of sounds; there is a sense of something grand going on, but one can never get the points of it clearly. I have both listened to and played Bach's organ fugues in a cathedral, and have always found the same result from the echo. When accompanying the Psalms to a simple chant the echo may, as I said, be made the source of fine effects, but all which *musicians* understand by music is destroyed by it; melodic outline and counterpoint are all reduced to a hubbub of "sound and fury, signifying nothing"—I am, &c., H. H. S.

CATHEDRAL ORGANS.

Sir,—"C. B. A." is evidently something more than a musical enthusiast, but I can hardly follow him in wishing to give the organ such prominence that for its sake the choir should have remained shut off from the main body of the cathedral. Another plan could have been adopted which would have been equally good for the organ and would not have injured the general effect. It

will be recollected that Sir C. Wren's first design did not contemplate a long nave for processional uses, but that it was forced on him by King



A.—Site of Organ.

James, and I think we can trace in the present building that the nave was no labour of love. Why not, then, have the organ placed in the same position in the nave as it held in the choir? perhaps better still place it one bay more to the west. The nave would then form the narthex or porch to the church, an appropriate site for all our monuments, the grand organ, where I still like to see it, at the west, and an unimpeded prospect, as now afforded, of the choir. The plan would be a Greek cross, with a prolonged choir.—I am, &c.,

E. E. S.

Intercommunication.

QUESTIONS.

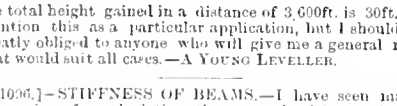
[1091.]—ANCIENT WRITING MATERIALS.—Can any of your correspondents inform me of a short account of ancient writing materials?—C. P. E.

[1092.]—LIQUID INDIAN INK.—Could you, or any of your correspondents, inform me of a way to preserve liquid Indian ink, so as to prevent its drying up?—T. E. B.

[1093.]—IRON PIPES.—I want to carry an iron main water pipe over an 8ft. opening. Will any of your correspondents let me know what size it ought to be to be able to carry the necessary quantity of water? The main pipes are 18in. in diameter, but the one to cross a span of 8ft. must have larger dimensions, which is what I wish to ascertain.—ALPHA

[1094.]—BARK OF TIMBER.—Can any reader kindly tell me what is the allowance usually made for the bark of trees in the purchasing of timber, and does it differ with the age of the tree or not?—BAILIFF.

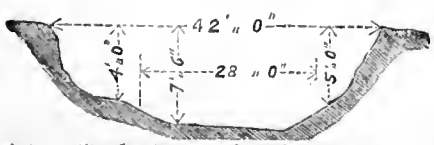
[1095.]—GRADIENTS.—What allowance should be made for the effect of inclines upon trains? How much is the resistance increased according to the steepness of the incline? Suppose I wish to calculate the additional resistance in the following case shown in the diagram, where



the total height gained in a distance of 3,600ft. is 30ft. I mention this as a particular application, but I should be greatly obliged to anyone who will give me a general rule that would suit all cases.—A YOUNG LEVELLER.

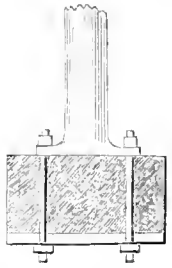
[1096.]—STIFFNESS OF BEAMS.—I have seen many rules given for calculating the strength of beams, but I am not acquainted with any referring to their absolute stiffness. In many instances, stiffness is required quite as much as, if not more than, mere strength. Would you oblige by ventilating this question in "Intercommunication"?—QUERIST.

[1097.]—WATERING OF RIVERS.—Given the section of a river, how is the quantity of water passing per minute to be ascertained? Let the section be as shown



what quantity of water passes in a minute, supposing the velocity measured by a float to be 25ft. per minute?—W. W.

[1098.]—SIZE OF BOLTS.—I am erecting some cast-iron columns, and they are fixed to concrete blocks by iron bolts (see sketch). What size ought the bolts to be? The



columns are 10in. in diameter, and are intended to carry the roof of a warehouse of large proportions.—CONTRACTOR.

[1099.]—AREA OF TRIANGLES.—I have measured the three sides of a triangle, and they are respectively 1,160ft., 965ft., and 945ft. I wish to obtain the area, but have been told that to do this I must first measure one of the angles. As I cannot use any angular instrument, would any subscriber let me know whether I have been informed correctly or not respecting the matter.—V. P.

[1100.]—A WASH TO CONFINE SANDSTONE.—Through your "Intercommunication," which I often read and find valuable information therein, I take the liberty to ask if you, or some of your readers, can inform me of a wash to confine the sand or powder coming from freestone when a syringe is used to water plants affixed to a wall? I have constructed a conservatory, the inside of which is wholly lined with Doulting stone, and creepers of various kinds will be running up wires close to the walls, and when the syringe is used the plants are covered with the white sand or powder. I have been persuaded to use a solution of alum, soap, and soft water. Will you kindly give me what information you can on the subject?—W. H. FOWLES.

[1101.]—CONCRETE BUILDINGS.—As I am about to erect a few working men's houses, I propose doing so in concrete. Am I at liberty to use any mixture for building such, and to proceed in any manner I choose? I know that Mr. Tall has a patent apparatus; I never saw such; but I have ideas of my own that I am sure will succeed. Any information on the above subject will oblige—A NORTHERN READER.

[You can use any mixture of concrete you please, but you must be careful that your mode of erecting does not interfere with the rights of any patented apparatus. Your best course would be to make yourself acquainted with the different patents taken out, full particulars of which the inventors would doubtless give. Mr. Tall's pamphlet can be had by sending 12 postage stamps to his address in London.—ED. B. N.]

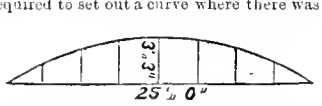
[1102.]—DOUBLE GLAZING.—How is double glazing to be effected in a single sash, so as to make and keep the inner sides of the glass perfectly clean?—A. PAYNE.

[1103.]—MEERSCHAUM.—I am a wood carver by profession, but find I can profitably occupy my leisure time by carving meerschaum pipe heads. Can any of your readers inform me where blocks of the material may be obtained, and whether there is any work which treats of the subject?—IRON MASK.

[1104.]—APPRAISER'S LICENCE.—I should esteem it a most particular favour to be enlightened on the following, viz:—Born a builder's son, I have practised all my life (business life) as an estimator, draughtsman, and quantity taker. Quarrelling some twelve months back with my then employer, I started in the same town on my own account, and have found plenty of employment in draughtsmanship, quantity taking, measuring up work, &c., &c. Now the query. If employed as above, when of course I am looked to to price or value the work so taken off or measured, do I require an appraiser's licence? I practised in all these capacities when (twelve months ago) I was clerk to a contractor. Now why should I not be enabled to do the same for (say) three or four different employers? At any rate, the uncertainty of my position makes it necessary to put the question. I do no more than every qualified clerk performs every day with impunity. Does the position of clerk or own master alter the case? for if so, I must have a licence at once.—C. H. KING.

[1105.]—CENTRIFUGAL FORCE.—Will any of your readers be kind enough to inform me what is the meaning of angular velocity, and how it is measured?—STUDENT.

[1106.]—SETTING OUT A CURVE.—I should feel obliged if some one of your numerous readers would kindly give me the following information:—Supposing it were required to set out a curve where there was not sufficient space to describe it from the point of radius; is there any method to find a number of points through which the curve could be drawn.—A MASON.



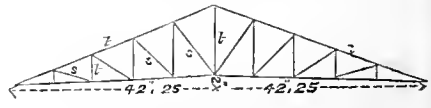
[1107.]—TOOLS FOR WOOD CARVING.—What is the cost of a set of small tools for wood carving, and where is the best place for obtaining them?—L. S.

[1108.]—FUNDS OF TRADE SOCIETIES.—I have heard that an act was passed during the last session of Parliament to protect the funds of trade and other societies. Will you oblige by informing me of the fact and indicating the provisions of the act?—W. R. T.

[The following is a copy of the act itself:—"Whereas it is expedient to provide for the better security of the property of co partnerships and other joint beneficial owners against offences by part owners thereof, and further to amend the law relating to embezzlement: Be it enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows: 1. If any person, being a member of any co-partnership, or being one of two or more beneficial owners of any money, goods or effects, bills, notes, securities, or other property, shall steal or embezzle any such money, goods, or effects, bills, notes, securities, or other property of or belonging to any such co-partnership or to such joint beneficial owners, every such person shall be liable to be dealt with, tried, convicted, and punished for the same as if such person had not been or was not a member of such co-partnership or one of such beneficial owners. 2. All the provisions of the act passed in the session of Parliament held in the eighteenth and nineteenth years of her present Majesty's reign, intituled 'An Act for diminishing expense and delay in the administration of Criminal Justice in certain cases,' shall extend and be applicable to the offence of embezzlement by clerks or servants, or persons employed for the purpose or in the capacity of clerks or servants, and the said act shall henceforth be read as if the said offence of embezzlement had been included therein. 3. This act shall not extend to Scotland."—ED. B.N.]

REPLIES.

[1051.]—STRAIN ON WROUGHT-IRON TRUSS.—Many thanks to "Calculator" for the trouble taken in replying to my queries. We agree very well as to strains of compression of rafter, and tension of tie rod at ends, &c.; but in the struts and queen rods we differ considerably. Does he not err in taking the whole load as acting on the struts and queen rods of one half the truss? It appears to me that only one half ought to be taken; but even then I do not make the strains so great. I presume, by "the



T are Struts, or in Compression.
S are Ties, or in Tension.

first strut nearest the end of rafter, &c.," he means the longest one nearest the middle of truss. I should feel much obliged, while on the subject, if he would give me the corresponding strains of the different parts. Supposing the truss to be arranged as in sketch, to compare the relative advantages of the two forms, I cannot see what bearing on my question the remarks of "R." have.—CONSTANT SUBSCRIBER.

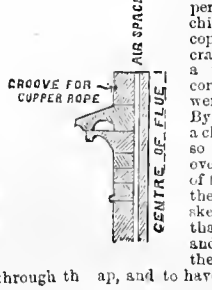
[1051.]—Would you please make the following correction in my formula, which appeared in the BUILDING NEWS of October 16? You will find it is put—

$$S = \sqrt{H^2 + \frac{W^2}{16}} = \frac{W}{4}\sqrt{\frac{S^2}{R^2} + 1},$$

Which I think, if you refer to my communication, is

$$T = \sqrt{H^2 + \frac{W^2}{16}} = \frac{W}{4}\sqrt{\frac{S^2}{R^2} + 1}. \qquad R.$$

[1059.]—FACTORY CHIMNEY FLUES AND SHAFTS.—I thank "H." for his kind endeavour to enlighten me as to chimney flues and shafts, although I consider his answer very unsatisfactory and inconclusive. I also think that he might have couched his remarks on my sketch in milder terms, and I trust he will find that my notions of masonry and equilibrium are neither queer nor ridiculous. I certainly had notions of my own before putting the question; but I also wanted the opinions of others. I have had to do with the construction of several mill chimneys, and live in close proximity to many lofty ones, and my observations of them lead me to offer the following suggestions. The smoke does not generally soak through the thickness of the walls so as to cause blackness on the outside, but it may be seen curling over from the summit of the chimney downwards, thereby disfiguring the exterior. Some time since I had the opportunity of examining stones and bricks from an old chimney then being pulled down. The smoke had permeated the brickwork which lined the lower part of the flue about 2in., while in the capstones, which went through the wall, the blackness had only penetrated ½in. on the inside, which formed the flue, and merely blackened the stonework externally. There are two chimneys within a short distance of me at this moment, one of which may be seen with the smoke drawing many yards down the sides, while the smoke from the other gets clear away. I am not able to account for this phenomenon. Unfortunately the wall line in the diagram given to illustrate my question was represented through the cap by a strong line instead of a dotted one; consequently it gave it the appearance of a joint instead of an imaginary line, forming, I fear, a stumbling block to "H." I have carried out the principle of the cavity on the outside of the wall line of a chimney cap, the profile of which was given me, and had it been carried out by bedding and overhanging the capstones, the whole concern would have inevitably have toppled down, the superincumbent weight being on the outside of the wall line, whereas by hollowing the overhanging portions of the stones the weight was thrown back on the thickness of the wall. Although I have ascertained, since I received my friend's answer, that lead was used to bind stones together in Pompey's Pillar, yet, as I am doubtful as to the properties of lead as a girdle for chimney tops, I would suggest copper rope instead; for iron cramps are well known to have a tendency to force away by corrosion the very stones they were intended to bind together. By permission I will introduce in a clearer form my first diagram, so as to show that the hollowed overhanging portions form part of the solid masonry resting on the bed of the wall. In this sketch I also show the air space that generally encircles the flue and is carried about half way up the shaft, to be continued forwards through the cap, and to have holes left at the bottom of



the shaft for the admission of cold air, which becoming rarefied would ascend probably with sufficient force to keep the smoke well up about the chimney cap.—L. M.

[1069.]—PATENTS FOR INVENTIONS.—Certainly not. The proposition put forward by "C. Watson" would be an infringement of the Patent Laws, which expressly forbid anyone to make or manufacture an article similar to the one protected by their agency.—PATENTEE.

[1074.]—RISE OF AN ARCH.—Square half the span of the arch, divide by the rise, to the quotient add the rise, and divide by 2 for the radius. This rule is founded on Euclid, book 3, problem 35.

$$\frac{1}{2}\left\{\left(\frac{25}{2}\right)^2 \div 3.25 + 3.25\right\} = \text{radius.}$$

$\frac{1}{2}$ (156.25 ÷ 3.25 + 3.25) = ,,
$\frac{1}{2}$ (51.3) = ,,
25.66ft. = ,,

"Carpenter" would find Euclid very useful in practice, as well as pleasant in theory.—R

[1074.] I must apologise to "Carpenter" for having omitted 3in. from my geometrical solution. I set the dimensions of "Carpenter" to small scale, at which the radius came so near the width of opening that I too hastily concluded the arch was described in the usual way—H.

[1074.]—"Carpenter" will find the radius of the arch he describes, where span and height only are given, by adopting the following rule: Square the half of chord line, divide by height of rise; add height of rise to product and divide by 2. The product is the length of radius, nearly 25ft. 8in.—BALCARRAS.

[1074]—"Carpenter" can obtain the length of radius by

$$\frac{C^2}{V} + V,$$

using the following formula:—R = $\frac{\quad}{2}$ in which R is the radius, C half span, and V versed sine or rise, applied to his case, will be =

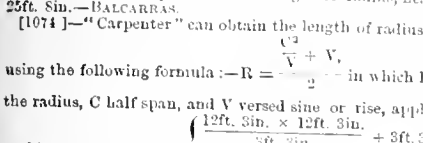
$$\sqrt{\frac{12\text{ft. }3\text{in.} \times 12\text{ft. }3\text{in.}}{3\text{ft. }3\text{in.}} + 3\text{ft. }3\text{in.}}$$

= 25.61ft. = 25ft. 7¾in.—H. S. P.

[1074.] In the various replies to "Carpenter's" inquiry for method to obtain radius of arch, two or three different lengths were given as radius to the arc, 25ft. span, 3ft. 3in rise. It will, perhaps, be some satisfaction to "Carpenter" and others to know that I set out the arc full size and found the radius required to be 25ft. 8in., as shown by "G. W. Usill" and others.—W. B. H.

[1075.]—LIMITS OF DEVIATION.—In reply to "Farmer," the limits of deviation within which a railway company may vary the centre line from the position defined on the deposited plans is 100yds. on either side of centre line for country district, and 10yds. for town or closely built districts. This does not, however, define the width of their survey for plan on which centre line may be laid.—H. S. P.

[1076.]—PRESSURE UPON VALVES.—Although not directly apparent, the question of the pressure of valves is a simple case of calculation, depending upon the laws of the lever. Thus, in the accompanying cut, let the value of W be 10lb. What pressure of steam would it require to lift the valve? Let the arms of the lever be as shown in the cut, the length of one being 3in. and that of the other



6in.; then the pressure to lift the valve may be determined from the following proposition:—Calling the required pressure P, we have P : 10 : : 6 : 3, and consequently multiply extremes by the means we find P × 3 = 10 × 6, and $P = \frac{10 \times 6}{3}$ = 30lb. At a pressure of 30lb., therefore, the valve would begin, technically speaking, to blow off.—ENGINEER.

[1077.]—CONTENTS OF SPHERES.—The following is the shortest rule I know to find the contents of a segment of a sphere:—

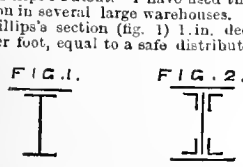
Let r = radius of base of segment, and h = height.
.5236 h (3 r² + h²) = solidity.
.5236 × 2.25 (3 × 4² + 2.25²) = ,,
1.1781 × 53.06.5 = ,,
62.51in. = ,, R.

[1077.]—The shortest rule I know of that will enable "A. B." to obtain the solid contents of part of sphere from the data given, is this: Solidity = .5236 × h² × (3 d — 2 h); or, in the case given, = .5236 × 2¼in. × (8in. × 3 — 2¼in. × 2) = 51.089 cubic inches. In the above, h equals height of segment, and d its diameter.—H. S. P.

[1078.]—EXTRA WORK.—"Builder's" course is perfectly clear. If the architect employed by the gentleman valued and certified for the extra work, he should summon the gentleman at once for the amount, subpœna the architect as a witness, and any jury will give him a verdict.—X. S. Y.

[1079.]—SIZE OF GIRDER.—The most economical form of girder is Phillips's Patent. I have used them with perfect satisfaction in several large warehouses. I would recommend Phillips's section (fig. 1) 1.in. deep, weighing about 50lb. per foot, equal to a safe distributed load of 23

FIG. 1. FIG. 2.



tons, being 3 cwt. per square foot of floor. An ordinary built up girder would require to be at the very least of section (fig. 2) web, 12in. by ⅜in., plates 5in by ⅜in., angles 2½in by 2½in. by ⅜in., weighing about 60lb. per foot, being 10lb. more than Phillips's.—ARCHITECT.

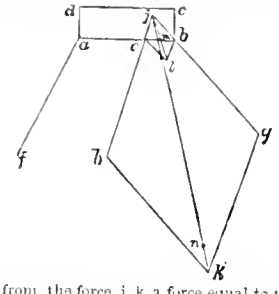
[1082.]—LIQUID GLUE.—Pour naphtha upon shellac until of a creamy consistency, and keep in a bottle, never allowing it to remain uncorked for any length of time. This glue will unite iron, wood, glass, &c., is quite waterproof and dries in a few minutes.—C. P. L.

[1082.]—To common glue add gently a small quantity of nitric acid.—R.

[1085.]—LAYING WROUGHT IRON JOISTS.—The joists ought to be laid as shown in "Carpenter's" sketch No. 1; because wrought iron having great tensile strength, and the load being placed upon it, would have a tendency to bend it and draw the wing asunder, just the direction in which wrought iron is the best able to sustain a strain; and, of course, just the reverse with cast iron. "Carpenter" has omitted the size of the joists, so that I cannot calculate the safe load; if he will give the dimensions I will do it for him.—L.

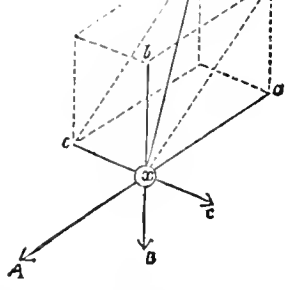
[1086.]—RESOLUTION OF FORCES.—"Student" must first find the resultant of two of the forces, say A B, which he will do by the "parallelogram of forces," a principle with which, as a student of mechanics, he is doubtless acquainted. His next step is to resolve the remaining force C, and resultant just obtained, into a second resultant by the same principle. This second resultant represents both in force and direction the three forces A B C.—J. J. C.

[1086.]—A force equivalent to two or more forces acting at different points on a solid body may be obtained by the use of the following proposition, called the parallelogram of forces:—If two forces be represented in magnitude and direction by the sides of a parallelogram, an equivalent force will be represented in magnitude and direction by its diagonal. Let a b c d be the body, and a b e the points in which the forces a f, b g, e h, act upon that body; produce e h and b g until they cut one another in j, and from h draw h k parallel to b g, and from g draw g k parallel to e h; then the diagonal j k represents a force equal to the two forces h j, g j acting upon the point j; but by the question the forces act upon the points e b respectively, so that



if we take from the force j k a force equal to that part of the resultant of the forces e j, b j, which lies within the body, we shall obtain a force equal to the forces e h, g b. From e draw e l parallel to j b, and from b draw b l parallel to e j; then from j draw the diagonal j l, cutting a b in m; cut off the length j m from the line j R; then m n is a force acting upon the point m, equivalent both in magnitude and direction to the two forces e h b g. The next step is to determine a force equal to the forces a f m n, which is done in the same manner as before. The diagonal is called the resultant of the forces represented by the parallelogram, and they are termed the components of the resultant force.—S. HURST.

[1086.]—As your correspondent is a "Student of Mechanics" he is of course aware of that primary law, the parallelogram of forces. Any number of forces can be compounded by this same law; for instance, as regards student's figure, let the body x be acted upon simultaneously by the three forces A B C, whose directions are expressed by the arrows, and their magnitudes by the lengths $x\,a$, $x\,b$, $x\,c$. Let him first compound any two of them (as A and B) by completing the parallelogram $x\,a\,b\,d$, by which he will find that the direction of their resultant is $x\,d$, and that its magnitude is to their magnitudes as the length $x\,a$ is to the lengths $x\,a\,x\,b$. He may then compound this resultant with the remaining force $x\,c$ by completing the parallelogram $x\,d\,e\,c$, the diagonal of which, viz., $x\,e$, will represent both the magnitude and direction of the general



resultant of all three forces; so that a force of the magnitude expressed by this length $x\,e$, and acting in an opposite direction to A B C would balance these latter forces. In this problem it matters not whether the directions of the forces lie all in the same plane or in different planes. In the latter case the three lines $x\,a$, $x\,b$, $x\,c$ would form the three edges that meet at one solid angle of a parallelopiped; and by completing this solid figure (as shown by the outer dotted line of the figure) its diagonal $x\,e$ will represent the resultant. Therefore, whether we regard the lines of this figure as they really lie flat on the paper, or as the projection of a solid parallelopiped the law is equally true. The same process is of course applicable to any number of forces, whether in the same plane or in different planes.—W. L. BERNARD.

WATER SUPPLY AND SANITARY MATTERS.

IT is anticipated that by the close of the year the first section of the operations of the company which has been formed to collect and distribute the Liverpool sewage will be completed. The section embraces the distribution of the sewage over a tract of sandy land in the neighbourhood of Ince Blundell. The Company intend ultimately to carry forward their operations to the borders of Southport. It is estimated that if the whole of the sewage of Liverpool were utilised and sold, a permanent annual revenue of £150,000 might be derived.

BUILDING AND LAND SOCIETIES.

THE second annual meeting of the Brighton and Hove Benefit Building Society, No. 4, was held on Friday evening last at the Town Hall, Brighton, the president, Mr. Alderman Bingden, in the chair. From the report presented by the secretary, it appears that this, the last established, is also the most successful of the original building societies of Brighton, 752¼ shares having been subscribed for, and 150¼ shares advanced on mortgage during the two years; the total amount of the securities being £12,148 10s. The chairman congratulated the meeting on the report, stating that 32 members had been assisted in the purchase of houses by the society in sums of from £38 to £1,007, and that 208 members had by their savings in the society during the past two years become entitled to a bonus on withdrawal of 12s per share. The report and balance sheet were unanimously adopted, and the officers for the ensuing year were elected.

WAGES MOVEMENT.

THE masons' strike at Aberdeen has caused the more energetic prosecution of a scheme already in progress for the formation of a co-operative company. The rules are now registered, and, a considerable number of £1 shares having been taken up, the company are prepared to commence operations. The architects are said to have promised them their countenance, and a fair number of jobs is hoped for.

The Coventry masons have given the masters notice of a new local code of rules, to come into operation on April 1, 1869. The hours of labour are to be 9 on Monday, 6½ on Saturday, and 10 on other days. That wages are to be 32s. per week, except during six weeks before and after Christmas, when they are to be 29s. per week. Sub contracting and piecework to be abolished, and no overtime to be allowed except on special occasions.

The dispute between the operative bricklayers of Liverpool and their employers is not yet definitely or satisfactorily arranged. Some weeks ago warrants were applied for against men who had interfered with some non-society men sent down from London by the Free Labour Association; and it was then stated that the officers of the trade society had given an undertaking that the non-society men should be permitted to work without molestation or hindrance. This undertaking seems to have been disregarded, for yesterday at the police court warrants for the apprehension of two men for illegal interference with the workmen in question were applied for. The solicitor who made the application said there was no doubt a formidable conspiracy in the town to drive the London men away. The warrants were granted.

LEGAL INTELLIGENCE.

A SURVEYOR'S CLAIM REDUCED BY THREE FOURTHS.—FROW *v.* THE BOSTON HARBOUR COMMISSIONERS.—The plaintiff, who is a surveyor and civil engineer residing at Holbeach, sued in the Boston County Court for 45 guineas rendered in November, 1866, in connection with a project for improving the outfall of the River Witham. His claim was for £47 5s for services rendered to the Commission, consisting in the preparation of plans, which, however, were not adopted, and in attendance both on the Commission and before a committee of the House of Lords. He called as a witness Mr. E. Millington, of Fleet, who said that, as a surveyor of great experience, he did not think Mr. Frow's claim at all unreasonable. The judge, however, thought differently, and decided that £12 12s., which the defendants had already paid into court, was ample remuneration for Mr. Frow's services.

A DISPUTED ACCOUNT.—HASTIE *v.* ELLIOTT.—The plaintiff, a slater, claimed, in the Newcastle County Court, of defendant, a builder of North Shields, £10 3s 8d., balance of account for work done. Plaintiff, at the request of Elliott, made a proposal for certain slating work at Bishop Buckland railway shed, amounting to £73. Defendant accepted the proposal, and the work was proceeded with. Before the ridge was gone on with, Mr. Bolland, clerk of the works for the North Eastern Company, informed plaintiff that Mr. Prosser, the architect, desired the substitution of a fireclay for a slate ridge, and a price was accordingly agreed upon—namely 2s 6d per yard, the price of slate being 3s. per yard. The difference was allowed, and certain sums of money were paid on account, leaving the balance now sued for.—The defendant pleaded that the fireclay ridge was stated at the time the alteration was agreed upon to be 2s. 6d per yard, while the contract price of the slate ridge was 4s. 6d per yard. The allowance claimed, therefore, was 2s per yard, or £8 14s for 87 yards.—Mr. Bolland, when sworn, said that great difficulty had arisen as to getting the slate ridge, and in consequence of the delay in getting it on, he suggested that fireclay should, with Mr. Prosser's consent, be substituted. Mr. Bolland said that a slate ridge would have had to be specially made to suit the peculiar roof, and that Hastie would have lost money on it at 4s. 6d. per yard.—Plaintiff, on the other hand, asserted that he should

be willing to supply any quantity of slate ridging at 3s. per yard —The items making up the difference between £8 14s. and the claim were settled, and the verdict was given for the defendant.

A CONTRACTOR'S LIABILITY. VESTRY OF BERMONDSEY *v.* MESSRS. LINDOW AND ANOTHER, THE EXECUTORS OF THE LATE WM. DETHICK. — Mr E. Thomas, instructed for plaintiff, stated that the action was brought for the expenses accruing to the reinstating of that portion of the carriage way extending from Drummond road to Unionbridge. The late Mr. Dethick began the work of the sewer in that place, which was completed by his foreman in September, 1867. The foreman (Mr. Walker) at that time waited on Mr. Elkington, the surveyor of the Vestry of Bermondsey, and stated that the road had been reinstated, and wished to surrender it into his charge. Mr. Elkington, inspected the carriageway or trench in question, and refused to take it as the representative of the parish under his charge, as not being made up to his satisfaction. A great deal of correspondence took place between the parties concerned, and on the 21st October, 1867, the Vestry came to a resolution to do the work themselves, and charge the defendants with the expenses of the same. That was done, and Mr. Elkington made out an estimate for the work, which said amount the defendants refused to pay. He contended that the Act of Parliament empowered the parish to do the work if it was not placed in the same state as before the commencement of the sewers. Mr. Elkington, the surveyor, was examined in support of the case for the vestry, as was also Mr. Ford, clerk of the works. On a suggestion by his Honour, a conference took place between the parties, the result of which was that defendants agreed to pay £10 more than they had paid into court, each party to pay their own costs.

IMPORTANT TO LOCAL BOARDS OF HEALTH.—On Saturday last before the Bucks magistrates, in special sessions at Slough, there were proceedings of considerable importance to local boards of health. Five residents of Slough, formerly members of the Slough Local Government Board, were summoned to show cause why warrants should not issue to enforce payment of £319 1s. 7d., surcharged against them by Mr. Barnes, the district auditor. It appeared that in the spring of 1866 the Slough Local Board opposed the bill of the Slough Gas Company in Parliament, and were unsuccessful (with the exception of one or two slight alterations), and the bill was passed. In the following June the five members of the board now summoned signed cheques for the payment of the sum named, being the costs of the opposition. The legality of these payments was challenged by some of the ratepayers on four grounds:—1, that it was an illegal expenditure by the local board of the money of the ratepayers as costs of opposing the Gas Company's bill; 2, that some of the members of the local board voting the money, and voting for a resolution in favour of opposing the Gas Company's bill, were members of a company of a like nature (an opposition gas company that had a bill in Parliament), and were, therefore, disqualified from voting; 3, that no such item of £319 1s. 7d appeared in the estimate of the rate out of which such payment was made; and, 4, that the resolution to oppose such bill was not made and passed in accordance with the bye laws of the local board. The auditor held that a local board has not any legal authority, direct or implied, to charge general district rates with the costs of opposition to a gas bill in Parliament; and that a local board, having a six months' retrospective power vested in it by the legislature to meet unexpected contingencies, could have no justification whatever to pay bills in June out of the proceeds of a rate made in the previous January, in the estimate for which they had not been included. The auditor accordingly disallowed the items which formed the £319 1s. 7d., and surcharged that amount upon the five members of the board who signed the cheques. An appeal was made to the Secretary of State and to the former clerk to the Local Government Board, but the appeal was dismissed by Mr. Gathorne Hardy, and the surcharge was confirmed. On a subsequent application to the Home Secretary for the remission of the surcharge, a local inquiry was held before Mr. Arnold Taylor, and upon that gentleman's report the Home Secretary refused to remit. The proceedings before the magistrates were taken under 21 and 22 Vic., chap. 98, sec. 60. After hearing the counsel on either side, the magistrates directed the issue of a warrant to recover the money at the expiration of a month, so that the defendants might, if so advised, appeal to the Court of Queen's Bench.

SCULPTURE FROM FRENCH CHURCHES.

WE this week illustrate three specimens of sculpture from different parts of France, Sens, Noyon, and Blois. We select these as being very characteristic examples of early date. Sens Cathedral contains many beautiful capitals of the type here illustrated, and the Noyon sculpture is not by any means inferior, the simplicity and elegance of the capitals being very striking. We have before drawn attention to the sculpture at St. Nicholas, Blois, in giving a lithograph of some of the capitals in a former number of the BUILDING NEWS.

Our Office Table.

A course of lectures on architecture will be delivered by G. G. Scott, R.A., Professor of Architecture, at the Royal Academy, on March 4, 11, 18, 25. A few tickets of admission are to be had at the rooms of the Institute, Conduit-street.

Mr. Holman Hunt, writing from Florence, says that unless speedy means are taken for the preservation of Titian's "Venus," it will soon be past restoration.

The entrance gateway of Burlington House, though in the course of being pulled down, is not to be destroyed. The Duke of Devonshire having declined it, we understand that its stones and bricks are to be piled up in Battersea Park for a time, until her Majesty's Government can agree as to its future destination. It would in our opinion be a much wiser thing to sell it for old material.

At the weekly meeting of the Metropolitan Board of Works on Friday last, Mr. Hows moved the appointment of a committee to conduct the business of the Board connected with parks and open spaces near the metropolis; but to this the chairman put a formal veto that the Board could not delegate its powers to any committee. Mr. Hows afterwards modified his motion, limiting it to the question of parks and open spaces being referred to a committee of the whole Board, a motion which was seconded by Mr. Westerton. An amendment was moved to this motion, which was put and negatived; after which Mr. Savage moved that a select committee of twelve members should be appointed for the purpose of planting and laying out of the parks, subject to the approval of the Board, and opening them for the health and recreation of the inhabitants of the metropolis in the spring of 1869. This was seconded, but after a long discussion it was negatived on a division by 16 to 10.

A correspondent writes to ask if some kind of interest is not at work to cause the commissioners for the new Palace of Justice to create sixteen additional cases for compensation. It is intended to form a communication with the Temple—either by bridge or subway, or both—and to enable them to do this they are about to serve notices upon the landlords and tenants of seven shops on the south side of the Strand, and nine houses in Thanet-place, also a block of buildings in the Temple abutting upon the end of Thanet-place, making, in all, a destruction of more than twenty houses, when, by moving the communication 20ft. farther west, an entrance could be effected to the Temple by the destruction of two places of business only, and would open into an open part of the Temple, thus obviating the necessity of taking four or five large houses in that expensive locality, in addition to sixteen places of business in the Strand and Thanet-place. The houses, &c., intended to be taken are those immediately adjoining Temple Bar on the west side and south side of the Strand.

A valuable paper by Mr. T. Van Herstelle' contribnted to the *Dietsche Warande*, as the first of a series, gives a brief account, with measurements, of a number of ecclesiastical buildings lately built or restored in the Netherlands. They are arranged alphabetically; and a certain number of them are illustrated by ground plans and transverse sections. Among the churches thus described are the parish churches of St. Laurence and St. Dominic, at Alkmaar, from the designs of Mr. Cuypers. The Church of St. Gertrude, at Jabeck, is illustrated by a ground plan; and that of Wijek (Naastricht) by a section. The parish church of the Name of Jesus, Oeffelt, has a most unusual and most unadvisable ground plan of choir. Its choir is an octagon in ground plan—added on to a nave which does not equal it in breadth. What is the advantage of this abnormal design? The parish church of Vechel is quite a cathedral in plan and scale, with an ambulatory round the chevet and an apsidal Lady-chapel projecting at the east end.

On Monday a public meeting was held in St. Mary's National School, Lewisham, for the purpose of organising classes for instruction in geometrical, mechanical, and architectural drawing, under a science teacher certificated by the Department of Science and Art. The Hon. and Rev. H. Legge occupied the chair. Mr. Buckmaster attended from the Science and Art Department, and delivered an address, in which he encouraged the young men to earnest work, and said that success in life depended more on continued effort than extraordinary natural gifts. A vote of thanks was accorded to the chairman and Mr. Buckmaster. The classes will commence at once.

Another considerable estate is now on sale in building plots between Redhill and Reigate, and a pair of neat villas already in course of erection on one of the lots. This neighbourhood, possessing as it does such extensive common lands and parks and salubrious air, seems likely ere long to become a most popular place of residence.

A rather singular accident was caused by the high wind which prevailed on Saturday evening last at the Church of St. Thomas, now in course of erection at Trowbridge, Wilts. One of the stone arches, 50ft. in height, in the interior of the building, intended for the support of the roof, and which had only been completed on the previous day, was discovered on Sunday to be leaning against the scaffolding which surrounded it. Not a stone in the structure was displaced, the arch being as true from the broken joints on either wall as when it stood erect. Had the scaffolding given way and the heavy mass had fallen to the ground, there is no estimating the loss Mr. W. Smith, the architect and builder, would have sustained; as it is, stone by stone the structure is being taken to pieces.

It is stated that in Germany timber rendered fireproof by saturation with silicates is extensively used for flooring planks, doors, and staircases.

The Exeter Court of Arbitration has issued the following advertisement:—"Exeter Board of Arbitration and Conciliation in the Building Trade. Umpire, E. Petersdorff, Esq. A Board of Arbitration and Conciliation having been established in this city, consisting of the following employers and workmen, viz., Messrs. Huxtable, Kingwell, Hubber, Lethaby, Westlake, and Martin, employers; Messrs. Wilcott, Halland, Delve, Reynolds, Chestor, and Hooper, workmen; feel it their duty to call upon all employers not at present connected with the Builders' Association, and upon all the artisans not connected with the several trade societies, to join at as early a period as possible in order that, should any dispute arise amongst them, the Board may have the power to arbitrate and settle the same, feeling assured that it will be the best means of placing the relations of capital and labour on a more satisfactory basis, and tend to promote a better feeling between employer and employed. Signed on behalf of the board, W. Huxtable, Chairman; J. Wilcott, Vice-Chairman; W. Kingwell, E. Reynolds, Hon. Secretaries."

Patents for Inventions

CONNECTED WITH THE BUILDING TRADE.

345 J. LIVESEY. AN IMPROVED MATERIAL THAT MAY BE USED AS A SUBSTITUTE FOR GLASS. Dated January 31, 1868.

Here the material employed is wire gauze, perforated zinc, or other open work, with the meshes or spaces filled in with a transparent composition, such as copal varnish, silicates, or other suitable transparent substances used alone or in combination with suitable gums or other materials, which are capable of withstanding the effect of atmospheric changes, and it may be manufactured wholly or partly plain or in colours. Molten glass may also be run or rolled into the interstices.—Patent completed.

351 R. C. SMITH. IMPROVEMENTS IN THE ARRANGEMENT OR CONSTRUCTION OF SINKS, ETC. Dated February 1, 1868.

This invention consists in forming the trough with a vertical ledge or projection on the back and two ends, whereas the front side is formed with a lip or overhanging ledge, so that the destruction of the fixings connected with such apparatus may not occur by means of the water overflowing on all the four sides as at present; the liquid in the vessel or trough, when full, up to the level of the front lip only, then overflowing the vertical edge on three sides of the trough, may be covered with timber or other material to give it a more finished appearance.—Patent completed.

387 T. W. WALKER. IMPROVEMENTS IN THE MANUFACTURE OF BRICKS, TILES, SLABS, AND OTHER LIKE ARTICLES, AND IN THE MATERIALS AND MACHINERY OR APPARATUS EMPLOYED THEREIN. Dated February 5, 1868.

The patentee claims, first, the general construction, arrangement, and combination of machinery or apparatus for the manufacture of bricks, tiles, slabs, and other like articles, as described and illustrated by the drawings. Second, the combination with the pistons or plungers of machines for compressing bricks, tiles, slabs, and other like articles of a self-acting expanding packing, arranged and operating substantially as described. Third, the moulding and compressing of bricks, tiles, slabs, and other like articles on a bed, plate, or table, by the aid of a mould box or frame and piston or plunger, substantially as described. Fourth, the peculiar composition or compound for the manufacture of plain or ornamental tiles and slabs, as described. Fifth, the production or manufacture of ornamental tiles by punching or perforating holes or openings through such tiles according to any desired pattern, and filling in such perforations at the time of laying the said tiles with mosaic work, or with other tiles of a more or less ornamental character, as described. —Patent completed.

404 J. HONEYMAN. IMPROVEMENTS IN ARRANGEMENTS AND APPARATUS FOR TRAPPING AND VENTILATING. Dated February 6, 1868.

This improved pipe trap may be made in earthenware or metal. It is formed with four openings, two of which, for the connection of the pipes leading to and from it, are at opposite ends, and are directed horizontally. The two

other openings are in the top, one on each side of the tongue or dipping part, whilst the bottom is hollowed out with an easy curvature to form the usual recess to retain water, the contact of which with the tongue forms the seal or trap. The top opening on what may be termed the drain or sewer side of the tongue is for the escape of foul air into the external atmosphere, so as to prevent accumulation of pressure which would force its way past the trap, and this opening may communicate directly with the surface or with pipes or flues carried to any height. The top opening on what may be termed the house side of the tongue gives access for thorough cleansing of the trap, and also in one modification admits fresh air by the house pipe into the house. The trap may be buried at any convenient depth below the surface, and communication with the top openings may be obtained by means of direct vertical pipes.—Patent abandoned.

415 M. O'DONNELL and T. ARKILL. IMPROVEMENTS IN RAISING AND LOWERING VENETIAN BLINDS. Dated February 7, 1868.

According to one arrangement, the inventors mount an axis upon the fixed top lath or bar (or otherwise) of a venetian or other blind. Upon one end or other part of this axis they fix a pulley, by preference of larger circumference than the axis around which the cord or line for actuating the axis and raising the blind is wound. The lifting line or tape (one or more of which may be employed) attached to the bottom lath of a venetian blind is attached to the axis, so as to wind thereon in the opposite direction to that of the cord around the pulley. Below the pulley a lever click is suspended on axis, so as to cause the pointed end or tooth on one of its arms to enter or fall into the teeth of a ratchet wheel fixed on the pulley. The cord wound on the pulley passes downwards through an eye or loop on the lower end of the other arm of the lever click. The act of pulling the cord to unwind it from the pulley raises or moves the lever so as to release its end from engaging with the teeth of the ratchet, at the same time causing the axis to revolve, and thus wind up the lifting line or cord thereon, but directly the cord over the pulley is released, the end of the lever re-engages with the teeth of the ratchet, thus arresting the rotation of the axis and retaining the blind in the position to which it was raised. The lowering is effected in like manner by disengaging the click from the ratchet, and allowing the weight of the blind in its descent to wind up the cord upon the pulley whilst held in a position to prevent the click from engaging with the ratchet.—Patent abandoned.

422 W. R. LAKE. IMPROVEMENTS IN LOCKS. (A communication.) Dated February 7, 1868.

This invention relates to locks of that class which are generally used on the front doors of dwelling-houses, and in which the latch is operated by two knobs, one on the outside and the other on the inside of the door, the outside knob being constructed in such a manner that it can be thrown in or out of gear with the latch. The invention also relates to certain improvements in padlocks or locks of any ordinary construction. The said invention consists, first, in arranging an adjustable screw in the end of the spindle in such a manner that, by the said screw, the length of the spindle and the position of the knob can be regulated to suit the thickness of the door. Second, in enclosing in the knob or handle the mechanism which serves to throw the knob in and out of gear with the latch. Third, in arranging a nut on the spindle in combination with a movable stump and tumblers in such manner that, when the tumblers are set, and the stump made to drop into the notches thereof, the knob is thrown in gear, and the door can be opened from the outside, but, if the stump is withdrawn, the knob turns freely on the spindle without having any effect on the latch. Fourth, in arranging a safety stop in combination with the knob and washer which form the socket for the said knob and with the tumblers contained in the knob, in such a manner that, when the said tumblers and the knob are brought into the required position, the stop can be made to lock the outer knob and prevent it being turned while the inner knob continues to act on the latch. Fifth, in arranging a cam in combination with the movable stump, and with the stop and tumblers in such a manner that, by turning the said cam, the stop and stump can be thrown out of or in gear with the tumblers, provided the tumblers have been brought in the required position. Sixth, in arranging an abutment between the keyhole and safety stop in such a manner that the stop cannot be reached or its position disturbed by an instrument introduced through the keyhole. Seventh, in the peculiar arrangement of a lever stop in combination with a series of loose tumblers.—Patent completed.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Royal Institute of British Architects.—Opening meeting of the session, 8. Address by the president, W. Tite, Esq., M.P.
Society of Engineers.—"Modern Gasworks at Home and Abroad," by Henry Gore, 7.30.
Entomological Society, 7.
TUESDAY.—Anthropological Society, 8.
THURSDAY.—Linnean Society, 8.

Trade News.

TENDERS.

EDMONTON.—For building factory warehouse, &c. Mr. J. W. Reed, architect:—

Hawkes	£1795
Humphreys and Son	1720
Carter and Sons	1670
Eaton and Chapman (accepted)	1616
Emery and Co.	1580
Linzell	1495
West	1473

STROUD.—For the erection of two shops and dwelling houses in Gloucester-street, Stroud, for Sebastian S. Dickinson, Esq. Mr. William Clissold, architect:—

Harper (accepted)	£976

BLETCHINGLEY.—For building new infirmary, rain water tank, &c., at the Workhouse, Bletchingley, for the Guardians of the Godstone Union. Alex. R. Stenning, architect:—

Knight	£3900	0	0
Morris	3800	0	0
Worsell	3891	0	0
Cooper	3600	0	0
Galyer and Moore	3550	0	0
Sherwood	3540	0	0
Cooke	3535	0	0
Grover	3495	0	0
Barnes	3400	0	0
Kesterton and Head	3293	0	0
Smart	3250	0	0
Webb and Sons	3250	0	0
Daniel	3200	0	0
Henshaw	3164	0	0
Till	3150	0	0
Macey	3109	0	0
Colls and Sons	3080	0	0
Bayes	3072	0	0
Nightingale	3063	0	0
Knight	3054	0	0
Regis	3050	0	0
Johnson (too late)	3049	0	0
Woodward	2900	0	0
Constable and Baker	2800	0	0
Gage	2510	17	6

BRIGHTON.—For the erection of a new warehouse and offices, Queen's road, Brighton, for Messrs. Latham and Sons. Benj. H. Nunn, surveyor:—

	Warehouse.		Offices.
Reynolds	£3237	...	£468
Kirk	3190	...	817
Nash and Co.	3182	...	769
Parsons	3143	...	747
Cheeseman and Co.	3140	...	800
Matthews	2974	...	750
Nightingale	2973	...	823
Lockyer	2906	...	710
Sawyer	2887	...	670
Anscombe and Newman	2803	...	741
Dean and Dickenson	2750	...	637
Kemp	2710	...	740

GREAT YARMOUTH.—For erecting new Congregational church, Gaol-street, Great Yarmouth. Mr. J. T. Bottle, architect, Great Yarmouth:—

Wright	£2984
Cooper	2962
Leggett	2860
Brown and Bailey	2834
Hood (accepted)	2826

LONDON.—For the erection of a shop, and alterations to premises, 176, Walworth-road, for Mr. E. Belcher. The drawings were furnished by Mr. Pierse Arthur:—

Langdale	£800
Day	750
Talbot	712
Weston	690
Brett	630
Lane	595
C. Davis (accepted)	610

LONDON.—For altering, repairing, and painting the buildings of the Borough Market, Southwark, for the Trustees of the Borough Market. Messrs. Henry Jarvis and Son, architect:—

Baguley	£2557
Thompson	2140
Hart	1292
Henshaw	1175

LONDON.—For rebuilding house and shop, Newington Causeway, for Mr. A. Bunnett. Messrs. Henry Jarvis and Son, architects:—

Hart	£825
Thompson	830
Henshaw	820
Carter and Son	797
Richardson	795
Taylor	793
Colls and Son	740
Baguley	721

SUTTON.—For the erection of four shops, and repairs to cottages, at Benhill street, for A. Dyett, Esq. J. A. Bunker, Esq., architect, 27, King William-street, Strand:—

	Shops.				Repairs.				Deductions.
W. Hatton	£680	9	6	...	£95	19	3	...	£6
E. Dawson and Son	622	0	0	...	96	0	0	...	10
Cuff	487	0	0	...	70	0	0	...	10
J. Hall	478	0	0	...	60	5	0	...	5
Totter and Ferrage	470	0	0	...	174	0	0	...	10

TIVERTON (Devon).—New mansion at Knightshayes for H. Heathcote Amory, Esq. William Burges, Esq., architect, Buckingham street, Strand. Quantities supplied by E. W. Crocker, Esq., Southampton-street, Strand:—

			Extra if in Henley stone.
Davis, Taunton	£17,000	...	£2,250
Williams, Canton, Cardiff	16,950	...	1,685
Myers and Son, London	16,749	...	600
Dove Brothers, London	15,995	...	5,400
Pollard, Taunton	15,980	...	2,000
W. and J. Webb, Birmingham	15,960	...	500
Escourt, Gloucester	15,520	...	3,450
Call and Pethick, Plymouth	14,646	...	250
Fatcher and Son, Salisbury	14,000	...	—

COMPETITIONS.

INDIA.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

MELBOURNE, NEAR DERBY.—For designs for a new Wesleyan chapel. Mr. W. H. Adcock, Melbourne, near Derby.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

HASTINGS.—November 16.—For the purchase of ashes, cinders, marine stores, and refuse of every kind. G. Meadows, clerk, Local Board of Health, Hastings.

COLCHESTER (Essex).—November 6.—For erection of officers' quarters, &c. Commanding Officer, Royal Engineers' office.

SPILSBY (County of Lincoln).—November 7.—For alterations and additions to the house of correction. Clerk of the Peace, Spilsby.

WISBEACH.—November 4.—For making and fixing about 4ft. elliptical cast iron culverts. W. Adams, C.E., Wisbeach.

OWLERTON, NEAR SHEFFIELD.—November 4.—For the erection of a new church. Messrs. Blackmoor and Mitchell, Withers street, James street, Sheffield.

DOVER UNION.—November 6.—For the erection of new buildings, &c., for the infirmary. W. Cross, Clerk to the Guardians, Buckland.

LEWISHAM (Kent).—For the erection of six cottages at Hither green. Messrs. Messenger and Grundy, architects, 1, Robert street, Adelphi.

TUNBRIDGE.—November 22.—For the erection of a villa. Mr. S. Cooper, 10, Laurence Pountney lane, E.C.

LEICESTER WATERWORKS.—December 8.—For the construction of a large storage reservoir, &c., and for the erection of an engine and boiler house, and other works. J. H. Williams, secretary, Waterworks offices, Bowling Green street, Leicester.

ST. MARY CHURCH, TORQUAY (Devon).—November 13.—For the erection of new gasworks in the Barton road. Grant Wollen, clerk to the local board.

PENZANCE.—November 28.—For the improvement of the harbour of Mousehole, in the parish of Paul, near Penzance, in Cornwall. Rodd and Cornish, solicitors to the Commissioners, Penzance.

CHATHAM.—November 6.—For improving the drainage of Brompton Barracks. Commanding Officer, Royal Engineer Office, Chatham.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

Frederick Beech, Hornsey-road, stonemason, November 5, at 2—Stephen Cavie, Tunbridge Wells, builder, November 6, at 2—James Richards, Palmerston-road, Plumstead-common, painter and glazier, November 5, at 12—James Canham and Robert Guiver Canham, Cambridge, builders, November 10, at 11—Thomas Hutchings, Montpelier road, Peckham, contractor, November 9, at 11.

TO SURRENDER IN THE COUNTRY.

William Cox, Tutbury, builder, November 6, at 12—John Edwards, Taunton, painter and glazier, November 4, at 12—Albert Thick, Woolston, Hants, builder, November 4, at 12—John and William Weeks, Painton and Dartmouth, builders, November 4, at 12—Giles Beard, Horton, Gloucestershire, timber dealer, November 6, at 11—John Lee, Primrose hill, near Huddersfield, stonemason, November 13, at 10—James Peters, Bristol, carpenter and builder, November 6, at 11.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

December 10, G. Warriner, Bedford-row, engineer—December 8, H. Keen, Mevrick road, Battersea, builder.—December 7, C. Goldsby, London Colney, Herts, builder.—December 8, E. Phillips, Leighton Buzzard, timber dealer.—December 10, W. Burnham, Chipping Wycombe, builder.—December 11, J. Dungey, Middleton street Clerkenwell, gas fitter.—December 11, T. W. Taylor, Colchester, builder.—December 11, T. Sheen, Holborn hill, ironfounder.—December 11, J. Baker, Toddington, plumber.—November 27, R. Court, Aston, near Birmingham, builder.—November 4, G. Beard, Horton, Gloucestershire, timber dealer.—November 4, J. Peters, Bristol, builder.—November 5, J. Wale, Leicester, builder.—November 18, T. Byard, Newent, contractor.—November 6, J. Somerset, Liverpool, joiner.—November 3, W. Lunn, Balderton, bricklayer.—November 17, O. R. Rowlands, Bangor, joiner and builder.—November 16, W. Playford, Woodbridge, sawyer.

SCOTCH SEQUESTRATION.

David Lindsay, Glasgow, builder, November 4, at 12.

PARTNERSHIPS DISSOLVED.

Carey and Garnett, Halifax, stone masons.—Speakman and Gerrard, Eccles and Swinton, builders.

THE BUILDING NEWS.

LONDON, FRIDAY, NOVEMBER 6, 1868.

THE ADDRESS OF THE PRESIDENT OF THE INSTITUTE OF BRITISH ARCHITECTS.

THE President, in his address at the first ordinary general meeting of the session, on Monday evening, and some of the speakers who followed him, touched upon sundry questions of considerable importance to the profession, upon which we would make a few remarks. The principal one was that of competitions, which is a vexed question indeed. Mr. Tite took occasion to review the proceedings in the case of the recent great competitions for the National Gallery and the Law Courts, which, though they may now be considered as settled beyond appeal, yet furnish a warning that for the future the regulations laid down and the conditions imposed and accepted should be more strictly and justly adhered to, if the most able men in the profession are to be expected to devote their time and their talents to the solving of architectural problems of such public importance. In those particular instances, as one of the speakers said, "It is time now to let the dead bury their dead;" and, as all seemed to agree that the result had been so far fortunate that the hands into which those two projected buildings have fallen are of first-class and acknowledged ability, and as Government has wisely abstained from trammelling them in their ideas, so that they are unfettered and free in every respect, a work in each case may be expected which will be an ornament to the metropolis. There are other public buildings to follow, and we would echo most earnestly the anxious desire expressed by Mr. Layard that the eyes of all concerned should be kept open, so as to prevent the occurrence of any gross blunders with regard to them, for the opportunities are such as have never before arisen, and may never arise again. The opening of the Thames Embankment must have rendered it evident to everyone that the sites it affords are those upon which the public buildings that are needed should be erected, and that if proper advantage be taken of them, the stigma passed upon London, as "the ugliest city in Europe," may once and for ever be swept away, for we unhesitatingly declare that no city, not even Venice, can boast of such a water frontage and such a noble stream passing through its centre. Alas! that the railway stations which abut upon its banks, and the bridges which cross it, should have been taken in hand just too soon, for had they been projected later than the completion of the embankment, not even engineers would have dared to have perpetrated such eyesores as they have done in its proximity. We must, in passing, take exception to the pungency of the strictures of Mr. Tite upon the Blackfriars Bridges; in our estimation, though open to strong architectural censures, we do not believe that they can in any way compete with the intense ugliness of those leading to the Charing Cross and Cannon-street Stations, nor be such defiant contradictions to the proprieties of metal design as that at Westminster. Time will shortly show, and we only trust that we are not taking too favourable a view of them; we also hope that the President is not mistaken in his anticipation that the long range of pavilions of St. Thomas's Hospital will hereafter be ranked among the few architectural successes of which London can boast.

Some very strong remarks, but not a whit stronger than the occasion deserves, fell from Mr. Godwin and Mr. Charles Barry as to certain competitions for various parochial infirmaries, hospitals, and other buildings now on foot. These seem reprehensible, not only on account of all names of eminence in the profession having been passed over in favour of untried men, but from the fact that the magistrates and authorities seem to have banded together to beat down the proper professional remuneration. As this is a subject which is under consideration of the council of the Institute, we look to that body for prompt and vigorous action in the matter. Many of the competitors who have acceded to the terms offered, which are insulting and degrading to the profession, are members of the Institute, and amenable to its discipline, and no half-measures can be dealt out to them. As it is, competition is the ruin of the architectural profession, and most injurious to the young men, the very class which it is supposed to benefit. They are brought by it into practice before they are fit, and though intoxicated by an early, seldom a deserved, success, they soon find out that one swallow does not make a summer, and that the system is a hard one which compels them to continual fighting and gambling to maintain the position to which it has raised them; and yet they cannot be surprised if the public use the weapon against them which they themselves supplied. We would ask Mr. Hope to take these points into consideration, for to him, as an amateur, the excitement of competitions may supply interest and amusement, and what may be death to us, may be only fun to him. Thus, when he asks "How is a young man without competitions to make himself known?" we might reply that we believe there are not quite so many architectural violets blushing unseen as he seems to suppose, and that if there were, the annual exhibitions would soon expose their fragrance, so that they need not long waste it upon desert air.

Another subject touched upon was the speedy completion of the new galleries for the Royal Academy, in respect to which no information was given as to whether any greater facilities are to be conceded to the architectural exhibitors than they have been used to—we can scarcely say—enjoy in Trafalgar-square. This is really a point which the Institute should agitate on behalf of the profession.

The only other remark made which we desire to notice was one by the President, deprecating the too rigid following of former styles, as being apt to degenerate into fashions: in this he was supported by Mr. Layard. Now, while there is much to say on this head, there is far more danger likely to result from the licence engendered by the opposite course. We are continually hearing of new styles, and of meeting the requirements of the day, but the efforts yet made which can claim any special novelty as Victorian are no improvements on the established styles. For our part, we would say, "Give us either good Gothic or good Classic, but none of your eclectic jumbles." Any requirement, modern as ancient, can be fulfilled in either. If they fail to be so, the fault is that of the workman, and not of his tools, of the architect, and not of the style which he employs.

THE ARCHITECTURAL MUSEUM.

THE council of this exceedingly valuable institution have just issued an announcement of the near completion of their new premises, which are situated in Bowling-street, Westminster, and they have invited their subscribers to inspect the home that has been there provided for the fine and unique collection of casts about to be removed from South Kensington. Much, they say, still remains to be done in the way of ornamenting the structure; nevertheless, almost the whole of the intended decorations have been liberally promised by various art manufacturers and workmen, and these are all expected to be completed and fixed in their places in time to permit of the opening of the Museum to the public, which ceremony is proposed to take place early in the coming year.

We heartily congratulate the council and subscribers on this highly successful result of their strenuous and praiseworthy efforts, for although the funds are at present exhausted, and an additional thousand pounds is needed in order to pay the balance due to the contractor for the building, we feel confident that the appeal they are compelled to make to the public for this amount will not long remain unanswered. The difficulties which have been encountered in the establishment of the Museum upon its present footing have been exceptionally great, and if the council had not at last boldly resolved almost to overstep the bounds of prudence in incurring this considerable debt, the whole scheme must have fallen to the ground, and the entire collection of casts would have been lost or dispersed.

It is, therefore, due to them under the present circumstances to make this perfectly clear, for which purpose, although the facts are familiar to many of our readers, we will give a short résumé of the history of the Museum. It cannot be denied that considerable impatience has been not unnaturally felt by many of the subscribers for some years past; this has arisen from their not having been able to see a sufficient or even any very tangible result for the long-continued sacrifices they had made in its behalf.

The Architectural Museum was founded in the year 1851, in order to supply means for the study of the architectural ornament of past ages, with the view of improving that of the present time. By obtaining and arranging casts from the finest ancient examples—English and foreign—it was intended to assist architects in designing, and workmen in executing, ornament, and to spread among the public a love for and knowledge of such artistic workmanship. In the first place, premises were hired in Cannon-row, Westminster, and the efforts made were so far successful that a large and valuable collection was got together, which was partly given and partly purchased. As this increased it outgrew the capacity of the structure in which it was housed, and the building, which was a mere timber shed, liable to destruction by fire at any moment, did not seem to be a fit and safe depository for contents of such value.

At this crisis, an offer having been made by the authorities at South Kensington to find space for it in their galleries, and the funds at the disposal of the council of the Museum being too small to admit of the payment of a heavy rental, negociations were entered into which ended in the transfer of the collection to that locality. The benefits conferred upon the two institutions at that time were mutual, for the Museum gained time in its infancy for development and growth, and was freed from the burdens which at that early stage would assuredly have proved beyond its strength, while the then unfilled galleries at Brompton received no mean addition to their attractions. Complete independence was stipulated for by the council of the Museum, and gracefully conceded to them, together with the free use of one of the theatres for the delivery of the series of lectures which they had established. By degrees, however, the objects of the two institutions were found not to be identical, for the one appealed to and strove to attract and gratify the general public, whereas the other was specially designed for the advantage of students—the one courted popularity and display, the other sought comparative retirement and repose. The latter thus found themselves denied the quiet and facilities they needed, while the former discovered little in the collection of architectural fragments of sufficiently striking interest to arrest their more cursory gaze. Under these circumstances, and convinced that South Ken-

sington was not the position likely to render their institution as useful as it ought to be to the working classes, for whose especial benefit it was intended, the council of the Museum sought long and anxiously either for existing premises suitable to their wants or for a site upon which they could erect such. The difficulties they encountered in this search were extreme, and required great energy to surmount. But at last they have been overcome, and the Museum may be said to be now placed upon a permanent and satisfactory footing. To give credit where it is due, we believe we are correct in attributing this successful result mainly to the indefatigable exertions and energy of Mr. Joseph Clarke, the honorary secretary, to whom also is to be principally attributed the design and superintendence of the building, for which he and Mr. Ewan Christian have kindly acted as joint architects. The thanks of the subscribers and all concerned should also be warmly accorded to the contractor, Mr. R. E. Roberts, who has executed the work in a most satisfactory manner and in a most liberal spirit, and we trust that he will soon meet with substantial "acknowledgments" in the shape of the payment of the large balance which still remains due to him.

Such is the history of the Museum. It now behoves us to speak of the material home that has been provided for it—of the collection itself we will defer any remarks till it has been transferred and arranged therein.

The site is a plot of ground within about two minutes' walk of Westminster Abbey, and may be approached from Great Smith-street, or from Dean's yard, the southern exit from which leads directly to it, and from which it is only a few steps distant. For the practical utility of the Museum this is a most excellent position, as it is in fact in the heart of the very district in which most of the art workmen and carvers of the metropolis reside.

The site contains upwards of 5,000 superficial feet. The frontage towards Bowling-street is about 40ft., and is occupied on the ground floor by the entrance in the centre and a small shop on either side. The façade is three stories in height, the two upper ones communicating with the galleries of the main building. The body of the structure is behind this façade, and is of the simplest charater, economy having been strictly kept in view. It consists, in fact, of but an outer shell of walling covered by a light iron roof, the greater part of which is covered with glass. A range of wooden posts divides it as it were into three aisles, the centre being open to the roof, while the sides have two tiers of galleries. The staircase is to be at the further end, rising from the centre and branching right and left. There is a considerable additional space or second court at the south-west angle somewhat similarly treated, from which two small rooms are partitioned off for the accommodation of the curator and porter of the establishment.

The only portion of the building which displays, or indeed which admitted under the circumstances, of architectural treatment and design is the street façade, which we now proceed to describe. The general material is ordinary red brick, with the gauged arches of rubbed superior bricks of the same colour, but there is considerable relief obtained by the use of stone, polished granite, tiles, and other materials. The main feature is the triple division resulting from the entrance archway and shop on either side. The wings are, we think, somewhat unfortunately made more prominent than the centre; they are comprised within lofty arched recesses, which are continued up to the top of the façade just below the cornice. These are pierced as windows only to the first floor, the space above being occupied by bands of ornament and circular panels within the arches. The mode of decorating these flanking arched recesses is, we think, happy, and the finest part of the whole. We will describe them again more in detail. The shops below are weak in comparison and little in harmony with all above. When will a shop be successfully treated? We fear other precedents must be sought than those at the Architectural Museum.

The entrance archway and the two-light window above, with its richly carved solid head under the comprising arch, are again separately effective and able, but the greatest defect in the composition, to our mind, is its stoppage at a lower level than the arches of the flanking recesses, and the consequent loss of the prominence which the centre of every such composition should have. It is but fair to say that this has been sought by other means, and that the statues and canopy on either side of the entrance will go far to redeem it in this particular. A square carved panel occupies the central space of the walling above the entrance, and a horizontal carved stone cornice with a parapet above, which has a series of arched recessed panels over each of the principal divisions of the front, completes the whole.

It will be seen by the above description that the design contains some unusually important and striking features, and an examination of their details will still further heighten the impression thus gained. Unfortunately, those parts from which most may be expected are so incomplete that it is hardly fair to judge of the effect of the whole in their present state, and we must defer any criticism as to their artistic excellence until they are finished.

The square panel in the centre which we have referred to may be taken as the post of honour, and is to be filled with the figure of St. George, carved in Sicilian marble by Signor Fabbricotti, from a design by Mr. Redfern. Next in prominence is the head under the comprising arch of the two-light central window of the first floor. It is a clever composition, in which several circular bosses are interwoven with rich foliage carving. One circle contains the design of the seal of the Museum, and those around it are to present portraits of the architect of the Parthenon, the architect of St. Sophia (Anthenius, of Tralles, in Lydia), and William of Sens.

The five polished red granite shafts of this window and those flanking it, which add greatly to the general effect, are gifts by Messrs. M'Donald, Field, and Co., and of Messrs. Fraser and Son, of Aberdeen.

The statues which are to occupy the positions on the brackets and under the castellated canopies in front of the central piles, in a line with the above shafts, are to be from the chisel of Mr. Earp and Mr. Farmer respectively.

Some oak tracery above the entrance door is given by Messrs. Rogers and Booth, of Gosport, and the carving of it by Messrs. Rattee and Kett, of Cambridge.

The circular panels in the heads of the flanking arched recesses are to contain busts in pale red terra cotta of William of Wykeham and Sir Christopher Wren, by Mr. Blashfield.

Below these are to be bands, 10ft. long by 3ft. high, by Messrs. Harland and Fisher, in their new painted encaustic tiles, representing processions, and these are set between bands of glazed red tiles with projecting green bosses, by Mr. Godwin, of Lugwardine. These bands are effective and rich, but they alarm us with visions of the plague of boils to which we shall be subject now that such facilities are presented to our present generation of boss-loving architects. Then the whole of the windows are to be filled with stained glass by various art manufacturers—three lights by Messrs. Clayton and Bell, two lights by Messrs. Lavers and Barraud, and one light by Mr. O'Connor, all of which are to be fixed in casements, which have been presented by Messrs. Burt and Potts, while quite a keen competition took place for the honour of giving the revolving shutters for the shops, Messrs. Clark and Co. having been successful in obtaining the opportunity, Messrs. Bunnett's offer having been sent later than theirs.

For the decoration and fitting up of the interior other liberal presents have been made and accepted, but the only one we could see in the present unfinished state of the building was a portion of the flooring which is being paved by Messrs. Maw with their enca tiles. Messrs. Minton contribute tiles for the centre of the larger court. Those for the lesser court will be by Oppenheimer, of Manchester; and another portion is to be laid with similar materials, from a design furnished for the purpose by the Rev. Lord Alwyn Compton, by Mr. W. Godwin, of Lugwardine. Walker, of Burslem, and Rust and Co. also make other presents of tiles. The walls of the lobby are to be decorated in part from cartoons furnished by Messrs. Clayton, Bell, and Co., and executed in mosaic by Dr. Salviati, partly by Messrs. Rust and Co., and partly by Messrs. Harland and Fisher, while other internal decorations will be furnished by Mr. Charles Hudson.

The Museum will be enriched with a considerable quantity of ornamental wrought-iron work from the workshops of many spirited manufacturers. Thus a balcony, whence lectures will be delivered, is to be given by Mr. Skidmore, and other articles will be supplied by Hart, Hardman, Peard and Jackson, Brawn and Downing, Richardson, and Slade and Ellson.

Many other articles of equal utility and cost, if less ornamental, will be contributed, among which we may name the sun-burner by Messrs. Strode and Co., staining and varnishing by Mr. Swinburne, a large stove by the London Warming and Ventilating Company, a washing apparatus by Mr. Jennings, while some furniture has been promised by Messrs. Cox and Son, and by Mr. Chapman, an art workman.

We think that the munificence and enthusiasm displayed by the above list of donations are most gratifying, and show an appreciation of the objects of the Museum on the part of the leading art manufacturers which almost guarantees its success; and we cannot doubt for an instant that a place for study which will be not only well-furnished with first-class examples, but replete with comfort, and positively sumptuous in effect, and which is planted among the very homes of the art-workmen, will be extensively used and enjoyed by them. We fear that the perusal of the list may create some disappointment to numbers who, had they been aware of such an opportunity, would have hastened in like manner to do what lay in the power of each towards the adornment or furnishing of so useful and popular an institution. We sympathise with such in their disappointment, for large though the structure is, it is not large enough for the display of every gift in kind that would have been lavishly conferred upon it. It is therefore positively a boon that there is so considerable a deficiency in the fund for defraying the cost of the actual building, to which such may still contribute in proportion to their means. There is not an architect who will not benefit if not directly by the Museum, will do so at least indirectly by the education it will furnish to those upon whom he depends for the execution of his designs; there is not a manufacturer of any article of general utility to whom it is not an object that the workmen under him should improve in intelligence and artistic power. The public who will employ the manufactures so improved are likewise strongly interested in the success of the Museum; so also are the workmen themselves, since, according to the use that they make of the advantages herein offered them, they will find their services at a premium, but on the other hand if they neglect them they will soon find themselves, in these days of increased international communication, left behind in the keen competition for employment which has become universal. We anticipate, therefore, that numerous architects, art manufacturers, and art workmen will at once hasten to enrol their names among those

of the subscribers. Of the public many also will doubtless swell the list, but to them we look rather for the future patronage of the artistic productions, the expected result of the movement of which this Architectural Museum is one of the most substantial and visible embodiments. Thus far we have addressed ourselves to the building and the more immediate and pressing necessity of providing for its cost. It must not be forgotten, however, that to maintain the efficiency of the Museum and to carry out properly the programme of the council, the exertions of its friends must not be relaxed. We believe that the authorities of the Department of Science and Art will liberally take upon themselves the removal of the present collections of casts and specimens and the fixing of them in their new home; possibly they may add to it some of their own casts of details, as their efforts are now more devoted to obtaining copies of entire works of art, and it is hoped that they may assist in the preparation of a catalogue of the contents of the Museum.

Further loans and gifts of casts have been promised by the Royal Institute of Architects, by Mr. Scott, Mr. Brucciani, and Mr. Octavius Hudson, and many others may be expected when it is known that there is ample room for their reception. The next point of importance, that of taking steps to make the collection serve its purpose of practical teaching, is, we learn, now under consideration of the council. Their past efforts in this direction have comprised the delivery of courses of lectures upon subjects connected with art, architecture, and art manufactures, together with offers of prizes "for the most meritorious specimens of stone and wood carving, metal work, glass and decorative painting, modelling, drawing, &c., in order to encourage and individualise the art workmen of the day." We hope that they will soon find themselves in a condition not only to follow out this programme, but even to develope it. To do this, however, they must have their annual subscriptions increased to about £600; they now only amount to about £300 a year, which they truly say is "a very small sum where the interests of so many are concerned." Earnestly wishing the Museum all the success desired and deserved by its council we now take leave of it in the hope of being able on a future occasion to refer to it when completed and in working order.

EDUCATE! EDUCATE!! EDUCATE!!!

IN these electioneering times we find even our placid selves catching the popular fever and breaking out into notes of admiration, and though the cry with which we head this article is shouted loudly at us from the broadest posters over all the country, and rampantly talked of from every platform, there is something else to be said about it which we have not yet heard. One want is much felt, one branch of elementary education in need of cultivation, and an addition is sadly required to those "three R's" which have been supposed to combine all that is necessary for human knowledge, and of this want we hear nothing. If to the workman there is a branch of knowledge which to him is more than another power it is the knowledge of how to draw, and yet it is strange to find how perpersistently this knowledge is looked upon as too good to give him—to give him at least, as healthy food. We see it doled out to him in little doses as a luxury, and he is taught to look upon it as such, and thus both the gift and its recipient are spoiled thereby. It is true we have provided a very costly machinery, which we have tinkered up from the Brompton Boilers to the Palace of Arts and Sciences at South Kensington. True, we have created many snug berths and built some very nice houses for its stokers and pokers. It is true we have branch establishments all over the country, with masters and assistant masters and certificated pupils, &c., &c., &c., but it doesn't work. The machinery, in fact, is much too cumbrous, and the worst of it is it won't make the article wanted.

Let us confess the fact, we have begun at the wrong end; we were so very sanguine about crowning the edifice that we forgot all about the foundations, and the wisest thing we can do now is to begin again in a better manner. Our first and greatest mistake was in providing separate schools and establishments for the teaching of drawing. Instead of looking upon it as an ordinary branch of elementary education, instead of treating it as a parallel to the art of writings or the art of grammar, the art of drawing has been looked upon, not as a necessary part of, but as an especial addition to ordinary knowledge, and the absence of it has not been esteemed ignorance. The very severance of it from the common curriculum of study has fostered this idea, and the consequence has been very serious. The acquisition of the rudiments of the art under the present system too often turns out a bane rather than a blessing, and the most conceited and worst class of workmen we know are those who have been unfortunate enough to win a prize at a Government school of art, They are puffed up with the wonders they have done and henceforth think themselves so much above their fellows that they scorn to be "artisans," and think themselves "artists," They soar to flights for which they are not fitted, and, Icarus like, fall in consequence too frequently to drown their senses and their aspirations in discontent and gin and water. This, alas! is no fancy sketch; many and many a career is summed up in this short sentence, and many and many an intelligent and able workman has been utterly ruined by this mistaken system, and the hundreds of thousands of pounds we have spent under the auspices of the Incubus who sits in South Kensington have worked more harm than good to the class who most needs our aid.

We will see what all our costly apparatus has done, and what part of it has been truly useful, in order that we may separate the tares from the wheat now that the wheat is fully ripe. South Kensington—it is somewhat ominous, by the way, how we speak of it as a separate power, an *imperium in imperio*, a state apart from "My Lords the Committee of Council on Education;" even its lawful title of the Department of Science and Art doesn't express it—South Kensington, then, has done great and excellent service by collecting what soon will be the finest museum of industrial art in Europe. By bringing together in its various loan collections many precious reliques of the art industry of the past, illustrating the study of the history of civilisation in the most brilliant manner, it has converted many a bric-a-brac collector from the mere hoarder of "auld nick-nacketts" to the scientific researcher in many a forgotten process, many a defunct handicraft, and leading to the revival of many a long-lost art. For this it deserves our warmest praise, and this we accord to it with the most grateful feeling, trusting that it may long continue to do such good work; nor do we begrudge the cost—though it is somewhat large—of what has thus been done.

Its passive instruction has been excellent, but *ogni medaglia ha suo reverso*, and its active teaching is execrable. Established at an enormous outlay with the idea of benefiting the arts of design—if there are such things—it has taught drawing to that portion of the middle classes which learned it before, and who look upon drawing as an "accomplishment." Its students are almost entirely composed of this class, attending until disgusted with its soulless routine, and then falling off to be replaced by others with the same result. Some few of the upper half of the middle classes who have not to work very hard nor very early for their living go on a little further and become a nuisance to their friends, and perhaps one here and there does something rather good. But very little comes of it all, and very little help do the industrial arts get in this way from South Kensington. An intimate connection with many branches of art workmanship has revealed to us how very few who have gone through a course of Government Art Training are employed in designing for art manufacturers. Some few undoubtedly there are, and here and there an able man, but it is very questionable if these would not have been much better without the forcing process they have undergone. As a rule, the best manufacturers seek higher aid than this, and notably that of architects. Owen Jones, Digby Wyatt, G. T. Robinson, W. Burges, E. W. Godwin, and many others have rendered far more aid to that improvement which has taken place in our industrial arts than the shoals of half-educated young men who, turned out of this would-be manufactory of artists, have found their whole life to be a commentary on that pregnant line of Pope's—"a little learning is a dangerous thing." Nor if we examine the results of the departmental training in the higher walks of art do we find anything worthy of all this expensive and cumbrous machinery. As we have recently had occasion to remark in these columns, there exists among us no special training for the artist; and the English painter, sculptor, or architect would sum up his career in those memorable words of Topsy, "spect I grow'd." The lack of any adequate scholastic training for the higher branches of art undoubtedly influences a baneful effect upon its growth, but in comparison with the enormous importance of the elementary education of the working classes this falls into comparative insignificance. It is at this important epoch, when so many men are honestly thinking of doing good by getting into Parliament, that we would especially urge the consideration of this question, and as every man nowadays must have a "mission," we should hail with acclamation the endeavours of some energetic and very persistent man who would wrestle with South Kensington. What is required is that the enormously expensive encumbrances which surround it should be lopped off, our special schools of "design"—heaven save the mark!—be done away with, and elementary drawing made to form a portion of the daily education in all our subsidised schools. Let the drawing-book and the copy-book take their place side by side, and, above all, let intelligent observation be more cultivated than neat execution. Not the least of the many evils of the present system of Government teaching is its cramping insistency on the fine wire-line style of drawing—the worst feature of the worst class of German training, which, by a strange fatality, it most persistently adheres to. Copies, supposed to be given to induce freedom of hand, are required to be executed in a style which forbids it, and objects having no especial interest to the pupil are imposed upon him *ad nauseam*. We would urge the attention of all interested in elementary education to the noble efforts and the wise direction made by and exercised in Belgium. Here drawing and writing are taught as necessities at the same time, and the first lessons are given with a piece of chalk on the black board. Rough, vigorous, intelligent outline is that which is demanded rather than mechanical precision. By this means free and prompt control over the muscles is acquired, rapid education of the eye ensured, and the legitimate end of drawing as a rapid means of description—an unmistakable shorthand—attained. In Switzerland, too, though drawing is not an obligatory portion of elementary education, the main end of the art of drawing is much better kept in view, and a recognisable representation is more sought for than high finish. In Prussia, where drawing is an enforced study on all, the schoolrooms are not hung round with neat moral texts (rubricated capitals and black letter illegible), but with large cartoons of figures, geometrical combinations, and draw-

ings of the common objects of daily life, whilst the primer or *handfibel* of the children contains small and detached portions of these as lessons in drawing. By this system the elements of composition are inducted and the syntax and prosody of the art of drawing taught with those of the art of grammar. We do not think we need do more than point out the increased range of observation thus gained as one of the causes why so much more progress has been made in Belgium, in Prussia, and in Switzerland of late years than with us. Contract after contract is leaving us. English civil engineers no longer find work abroad. The increased intelligence of their workmen outstrips ours in the race, and our country is losing its prestige, its power, and its trade. Meanwhile we have spent egregiously and suffered long. We sincerely hope that in the re-reformed Parliament now being elected there will be found some who will think seriously and do well for the workman, some who will recognise that the true wealth of his country lies in the intelligence of her people. Should they be found, we can promise them much present obloquy, but much future gratitude if they will struggle long and hard to strangle that fictitious fostering which has poisoned—not nourished—the elementary art-education of this country; and we would impress upon their minds the fact that the truest patriot is he who most helps the people to help themselves. Archbishops, archdeacons, and archpresbyters, of all kinds, have lately lectured the poor workman about getting drunk, but the only way to prevent the demand for fictitious excitement is to give to the mind a wider range, a greater faculty of observation, and thereby a greater source of pleasure, than can be obtained by debasing means. With this faculty of observation will come the power of reflection and comparison, and the increase of these mental qualities will obviate many evils now caused and endured by the working classes; and for these reasons we would urge the adoption of the best means of cultivating them. Compulsory education will come. Factory acts enforce it in part, but meanwhile we would urge the introduction of the art of drawing into every school, and for this important branch of learning we raise the cry we began with—Educate! Educate!! Educate!!!

TIMBER IN ALGIERS.

THE worst evil to which colonists can be exposed on settling in a new and undeveloped country is the want of water, and the next worst is the dearth of wood. Although the climate may not necessitate the use of a fire for the purpose of simply raising the temperature, yet the exigencies of the preparation of food will demand its constant employment. Any country that is well wooded and well watered, even if the soil be but moderately fertile, is calculated to answer the expectations of the emigrant, and in the long run reward him for the time and money he may lay out upon its amelioration. It was for a long time supposed that Algeria possessed no forests of any importance, and it was not until the London Exhibition of 1851, and that at Paris four years subsequently, that the supposition was proved to be a popular delusion. The display at the latter Exhibition of over three hundred different descriptions of timber corrected the false impression commonly entertained, and demonstrated that the French colony, especially the department of Constantine, was rich in timber and forests. Neglecting small wood, the total area of timber-producing land may be taken at five million acres. This vast extent of ground is covered by no less than 140 different descriptions of trees, of which 60 at least are suitable for employment in the various manufacturing and industrial arts. Only a few of these, comparatively speaking, have been actually utilised. They include several varieties of oak, the pine, thuya, cedar, citron, walnut, juniper, elm, mastic, and ash trees. Similarly to all other materials these woods may be classed under three general heads or principal divisions. The first of these includes all those adapted for purposes of actual construction, which may be properly termed large timber; the second, the woods suitable for joinery and house carpentry; and the third, those fit for cabinet and inlaying work. All the varieties of oak answer well as a constructive material, but the green oak and the specimen termed zeen are particularly esteemed. When the Turks occupied the country, previously to the expedition under Lord Exmouth, they built their war ships of the latter timber. It is at the present time largely employed for shipbuilding, and also for railway sleepers. One objection raised against it, and one to which every kind of wood is liable, is that in drying it warps considerably. This objection is, however, more specious than real, and can be easily mitigated, if not altogether obviated, by the adoption of proper preventive measures. In point of density and toughness these woods are superior to those of a similar description grown in Europe, and could replace them with great advantage. Their price felled in the forest is about 1s. 3d. per cube foot. In addition to these two kinds, there is a third extremely well adapted for the manufacture of furniture and the interior fittings of houses, such as wainscotings, panelling, and flooring. The appearance of this wood is very handsome; its colour is a deep red, black at the heart, with brilliant rings and a fine close grain. It takes a splendid polish, and retains varnish with great permanency.

From the earliest times, especially in Oriental countries, the cedar has been justly esteemed as occupying one of the foremost places among trees adapted for the construction of buildings. The request in which it was held in the days of Solomon, not only by him, but by other nations, is known universally. Both the provinces of Algar and Constantine are abundantly supplied with this magnificent produce of the forest, which frequently attains a height of 70ft., and a girt at the base of over 18ft. These unusual dimensions render it very serviceable in heavy carpentry, where balks of long lengths are required, and for which it is equally well adapted by reason of its other favourable properties. It is resinous without being sticky or gummy, and is readily worked by the hatchet, the saw, and the plane. For ornamental purposes it is invaluable, since, in common with all fragrant and scented woods, it possesses the advantage of being unassailable by insects. Its price, in the rough, is nearly sixpence per cube foot. Another Algerian tree, the Alep pine, reaches to an altitude of 60ft., and were our supplies from Russia and Norway to fall short, or to be cut off by any unforeseen contingency, we should be able to obtain any quantity we might require from the French colony. The price of this African pine is about the same as that of the cedar, and it is extensively employed in shipbuilding, and also makes capital posts for carrying the electric wires upon. The olive is another wood peculiarly suitable for furniture of an ornamental character. Some of them have diameters at their base exceeding 10ft. Both the elm and the ash grow to great size and perfection in Algeria, and can challenge honourable comparison with their European congeners. The price of the other ornamental woods mentioned at the commencement of our article varies from fourpence to sevenpence the cube foot.

The tree the best adapted, by virtue of its special qualities, for cabinet work, is the thuya. No other wood can compare with it for the beautiful manner in which it is marked and the richness of the veins presented by the trunk. Its grain is fine and close, rendering it susceptible of an exceedingly high polish, and it affords every variety of tint, from a bright crimson to the rosy colour of freshly felled mahogany. About 2s. per cube foot is the price of this highly ornamental wood in the rough. Not content with the timber that is indigenous to the country the colonists have introduced others from different lands. Some years back the blue gum, *eucalyptus globulus*, was imported from Tasmania. In its native soil this tree grows to almost a gigantic size, and, in addition to possessing all those qualities rendering it a serviceable constructive material, it is endowed with the peculiar property of emitting an aromatic odour, which, it is stated, exercises a purifying influence upon the surrounding atmosphere. From the above particulars it may be fairly presumed that the opening up and working of the Algerian forests, which at present are scarcely touched, will ultimately prove a source of great profit and emolument to those who have the capital and enterprise to commence and prosecute the necessary operations. France alone consumes annually nearly seven million cubic yards of timber. A third only of this quantity is obtained from its own forests, and she is, therefore, compelled to rely upon foreign sources to supply the remainder of her demands. There is no doubt that were the colonists to establish a timber trade upon an extensive scale, they could not merely supply the mother country at a cheaper rate than Russia and Norway, but would in all probability come in for a large share of our own importations in that branch of commerce. It is astonishing how rapidly any well-organised description of traffic developes itself under proper management and liberal conditions. The northern portions of Europe have long had almost a complete monopoly of the timber trade, so far as their own productions are concerned, and it is time that other countries possessing equal natural resources of a similar character should make an effort to rival them, and send into the great national markets the produce of their own forests and plantations.

ARCHITECTURAL ASSOCIATION.

ANOTHER session of this association was commenced on Friday evening last by a *conversazione*, which was very fully attended. A fine collection of embroidered needlework, by Brangwyn and Co., of Bruges; a display of Venetian and Bohemian glass, by Salviati and Co.; specimens of a new tile decoration for walls (referred to by the president); two sections of the old box front of Her Majesty's Theatre; and several series of well-executed sketches all contributed to the interest of the meeting. The following new members were elected:—

H. Marsh, W. Hilton Nash, James Williams, J. O. Butts, Owen W. Davis, Robert Blackmore, S. D. Pettit, Luke Ward, G. Y. J. Blackburne, A. Edwards, R. L. Cox, W. L. Bernard, R. Whichelow, T. C. Yates, R. P. Wood, T. Benskin, W. Frame, A. G. Winsor, W. Penstone, W. H. Saunders, George H. Hunt, R. S. Besant, E. Evans Cronk, W. J. Cuthbertson, Berman Swinstead, Walter Miller, Charles C. Petley, John Calder, W. H. Espenett, and C. Greaves.

The following prizes were then awarded:—

The Architectural Association's prizes for the best essay upon the influence of art upon literature or the history of stained glass:—First prize, Mr. Lewis F. Day; second prize, Mr. C. H. Boyes.

Prizes offered to the Class of Design for the best series of sketches contributed in the class:—First prize, Mr. Walter Evill; second prize, Mr. Walter L. Spiers.

Prize offered to the Class of Construction and Practice, for the best summary of subjects treated in the class:—Mr. C. Bell.

Prize offered to the Figure-drawing Class for the best series of studies in the class:—C. H. F. Lewes.

Prize offered by the Architectural Union Company for the best series of measured drawings from existing buildings:—Mr. W. Henman.

Mr. Tite's prizes for the best design for a church to seat 800 persons in a street of lofty houses:—First prize, Mr. Walter L. Spiers; second prize, Mr. Arthur Hill.

Mr. T. Roger Smith then rose, and in a somewhat lengthy speech highly eulogised the labours of Mr. J. Douglass Mathews (who has been one of the honorary secretaries during the last five years), and concluded by presenting to that gentleman in the names of the subscribers (about one hundred in number) a handsome épergne and a number of valuable works on architecture.

Mr. Douglass Mathews, in thanking the doners, said that in receiving their testimonial he felt that he was taking much that belonged to others, for to his colleagues was due much that he was credited with.

THE PRESIDENT'S ADDRESS.

Mr. WILLIAM WHITE, F.S.A., F.R.I.B.A., commenced his inaugural address by congratulating the Association upon the work that it had done and the success it had achieved during the past year. The influx of 120 members during the year, and the selection of 35 more at one meeting, showed that the Association was in a flourishing state. It was refreshing to find an Association in these days of which it could be truly said that the work it did was greater than the noise it made. The work which the Association had to accomplish was great, and to the accomplishment of that work it was devoting all its energies. Nothing could be a greater work than that which encouraged mutual improvement amongst those who had only themselves to rely upon for their education in that technical knowledge which was indispensable to them. If he expressed any misgiving as to their choice of president this year, it was not because he had any lack of interest in the work, but because he might not be able to afford exactly that kind and that amount of help to the work which their confidence had a right to claim and expect. An opportunity lost was lost for ever; an opportunity seized and used was a sure stepping-stone to further advancement. This thought afforded an opportunity for urging upon the junior members especially of the Association the advantages which they would derive if in the discussions upon subjects treated of at the general meetings they would not let slip any opportunities of gaining and of giving instruction, such as asking questions of those who gave addresses or read papers, and suggesting reasons for or objections to any argument or fact brought before them. This might be the means of bringing out some further truth or illustration throwing additional light upon the matter. The Association was essentially one for mutual improvement and encouragement, and this should not be lost sight of. If any investigators or teachers in any branch of art did not enjoy the members' confidence, yet, as George Herbert says—

> Do not grudge
> To pick out treasure from an earthen pot.

Something might be learnt from everybody, and an accumulation of small items of knowledge might prove of great value. But besides being an association for mutual improvement it was also, to a very great extent, one of mutual co-operation for the purposes of education. The various classes were happy in their selection of able professors in their several departments of study, and the formation of these classes was the most hopeful sign of permanent success. The very idea of *mutual* education implied in some respects a weakness of system and of position but one degree removed from *self* education. An establishment of students without a body of professors and without a college was in itself an anomaly. It showed the greatest possible desire amongst learners to obtain knowledge, but it showed that no authorised sources were open, or at all events no sources which were equal to the demand made for them. And it was not quite free from the pernicious effects almost inseparable from any system of licentious self-government. This was exemplified in the working of the Class of Design in several particulars. It almost necessitated an expenditure of unremunerative labour from the attempt made to ignore or reverse the good old maxim, "Out of nothing nothing comes." Pragmatical attempts at design were sometimes induced before the store of either practical knowledge or æsthetical power was sufficient for the task, and it was destructive of the formation of individual character. It was like the universally-deprecated evil of allowing a child of ordinary capacities to extemporise on the piano whilst still unpractised in the scales, still uninitiated in counter-point, still unversed in the works of the best composers. This was denounced as a practice the most destructive possible to future knowledge and power in music, and it might be the same with the art student. Without deprecating the attempts made for mutual improvement, he (Mr. White) would endeavour to give an intelligible rule and reason for the guidance of future students. In some such way as that instanced the mutual improvement system showed an unwholesome state of things, to remedy which the best efforts should be made. It might take long to prepare any permanent or satisfactory scheme, but the idea of it must be kept steadily in view—it might be for years—until it was fairly started on a proper footing.

The wide question of art education demanded the best attention. For a true and permanent development, it was of but little use for anyone independently to follow his own devices as to what was right and wrong, but all ought to aim at perfection in some one given direction. And, in order to this, education ought to be systematised, and to a considerable extent centralised, in the same manner as the higher branches of education generally are centralised in our universities. But so long as one teacher led in one direction and another in an opposite direction, so long as there was no common consent as to the first principles of design, our work must be feeble and our progress slow. Upon the student was thrown the burden of weighing the claims of rival views and opposing theories when his energies ought to be more exclusively devoted to the acquirement of knowledge and of expertness in a course of ascertained results. Some sort of convention in art was not only desirable but essential to a healthy condition and to a successful development. That mere whim was not a leading motive in any age preceding the decline of its architecture was evident from the fact of the wonderful agreement in each successive era of the way in which all architects, even with a difference of detail, followed the same manner in the treatment of its ornament when reproducing any typal variety of natural formation. In these days any such conventional treatment would be regarded as destructive of that spirit of originality which gave a character to all true art. But by learning to be truthful we might fairly hope in due time to go on and be original. If originality was made our first goal it would be long before we arrived at truth. Just as pretentiousness in a building was destructive of its character when any approach to poverty was shown in the thinness of its construction or in the unfitness of its material, so also was originality destructive of character if it had not a basis of truth whereon to rest. Originality exhibited the highest development of the imaginative faculties, but the originality of a feeble imagination or of an untutored mind would offend either by its pretentiousness or by its poverty. In these days of morbid craving for something new and striking, and of ardent desire to avoid tameness, the snare into which all were likely to fall by aiming at that to which they had no real claim must not be forgotten. At the same time, students must beware of committing themselves to an education too exclusively technical, remembering always that architectural art embraced the truly æsthetical as well as the essentially structural. Whilst guarding against a spurious originality we had equally to guard against a despondency at the slow progress made towards a good and enduring standard of practice and taste. Drawings could be made *ad libitum*, but early opportunities for the display of great things in durable material were comparatively few. It was only when built that the true expressiveness of a design could be properly realised.

The claims of a liberal education in order to qualify an architect for his work were hardly recognised as they ought to be. The cultivation of mind and refinement of taste which such education alone could give were amongst the wants of the present age. In the desire to impart an early knowledge of the technicalities of the art, care should be taken lest valuable time for early training should be lost. There was no fear of failure in the practical and scientific branch of the profession; but in the midst of a money-making age it was of the greatest consequence that there should be a deep and widely extended under-current of poetic feeling and unselfishness which should impart tone and power to what would otherwise degenerate into a merely practical and commonplace display of magnificence or of luxury. Forms suggested by the study of the ancient edifices of Athens or of Rome, or of the more recent period of the middle ages, might be taken as a basis of design, or, it might be, some compound of the two great eras of architectural development, in all cases of course being largely influenced by modern requirements and by all the resources which science had opened up. But let this be done ever so studiously and conscientiously, the model would not be approached in spirit and feeling if this great under-current was wanting. The intellect must be educated and the imagination cultivated, or the minds and feelings of others could not be impressed. What was the origin of the great Gothic revival? Who was it that first of all inspired the nation with a desire to understand and appreciate the genuine beauties of our national mediæval architecture? Was it Grose or Britton, Pugin or Ruskin, Rickman or Scott, or the host of others who had more or less vividly brought forward the forms and features of the works of our forefathers? No. They supplied a demand which had been created by a far different machinery. It was to such men as Sir Walter Scott that we were indebted for sowing the seed which had grown up, and was now bearing plentiful fruit, by bringing into popular notice and estimation the associations which gathered round the neglected and ruined remains of England's greatness in the middle ages. But it was urged that it was the buildings, not literature, which influenced Sir Walter Scott. This, however, was only another phase of the same mistake. It was literature and the careful study of ancient authors which called his attention to the buildings, and taught him to love and admire their beauties, at that time hidden from his fellow countrymen. When a merit was made of denying or depreciating the connection of poetry with architecture, or the influence of literature upon it, it was a sad evidence of a great national deficiency. It would be wrong not gratefully to recognise the work which Mr. Ruskin had done by throwing into popular form many of the principles of design which pervaded mediæval works. Well did he say, in speaking of modern attempts at revival and architectural education, that what was wanted was not so much to teach men to design *from* principles—which was an impossibility, for design could not be taught—as to educate the nation into a poetic frame of mind. It was urged, on the other hand, that the remains themselves, and the delineators of them, led to the present revival of Gothic architecture. Though true, this was but a small portion of the truth. It was the engine *minus* the steam. If it were the whole truth, it would be impossible, on the one hand, to account for the fact that those very buildings had exercised little or no influence upon the architectural mind of England for the last three hundred years until the present century, although before the eyes of the nation during the whole of that period, many of them in a far better state of preservation than they now were. On the other hand, the revival of the so called Classic art in England took place on the revival of Classical literature. Literature and the study of ancient remains represented the two great influences which were ever bearing upon architectural expression and practice. The study of precedent would naturally have the most direct and immediate effect upon form and style; but literature, though indirect and more slow in its operations, was none the less sure and deep in its influence upon the feeling and spirit which always underlaid that form if it was to express more than a practical purpose in its conception.

The report of the Society of Arts upon the subject of technical education was deserving of special attention. This was taken up warmly by the late president, Mr. Phené Spiers, in conjunction with Mr. [illegible], who were deserving of the thanks of the Association for the great attention which they gave to the subject, and for their supplementary report calling particular attention to the necessity of a liberal education for the architect, and of proper drawing classes for the purpose of perfecting his education. During the present year, the importance of the study of art as a material branch of a liberal education at our universities had been brought before the world by the noble bequest by the late Felix Slade, F.S.A., of £35,000 for the sole purpose of endowing professorships and scholarships at Oxford and Cambridge, but chiefly in London, University College being named as one of the recipients. There was hope, therefore, of some speedy improvement, for the scheme had to be matured within two years from April last. Long before this bequest was made the Professor of Architecture in University College, Mr. Hayter Lewis, had drawn up a scheme for the extension of the study of the fine arts as a branch of general education for all classes. A more comprehensive scheme than that implied by the bequest had been adopted by the Senate, and would doubtless have been carried into execution by the council had not the Slade bequest checked the development of the scheme for a time by bringing increased force into play. A proportionately large scheme had already been suggested, and to a certain extent matured, by an influential member of the council of the college. The scheme, though thrown out as a mere sketch, was excellent and well considered, but it was seriously to be questioned whether it was in accordance with the intentions of the testator. A still graver question, however, arose whether it would be practicable and acceptable to the public, as competing against and clashing with the old-

established educational system of the Royal Academy, the *prestige* of which ought not to be divided by a rival body, whatever might be the imperfections attaching to its present working. What a noble supplement might be made of Mr. Slade's bequest if it were used rather as a nursery to the Royal Academy to force that institution to take more active measures for the fullest development of its resources for the education of the masses of art students generally. Whatever course events might take, the legacy might have most important bearings for the members of the Association, as opening the door to a higher system of education in the fine arts than could now be acquired. It remained to be seen whether architects might not, after all, be left out in the cold dark—whether all that they had been craving and clamouring for as the very keystone of their position was to be simply ignored or gracefully recognised by those who had the disposal of the fund. Happily there was no need to put the question to the Association whether or not it considered the study of painting, sculpture, and drawing from the nude and from the model as integral parts of an architect's proper education; nor yet whether these branches of art were the guardian angels which condescended to take their young *protege* called Architecture under their patronising wings. The Association had already shown by its several classes—so ably conducted and so well attended, established by mere co-operation amongst those who were deserving of far higher opportunities—the recognition of the absolute need of these studies as an integral part of architectural education; whilst its very foundation (the members out of which it arose having been a drawing association) is witness to the fact of its maintaining the position of architecture as embracing and holding together in one all its subsidiaries. He (the president) would lose no opportunity of bringing forward before anyone who might have influence with those concerned the claim of architecture to be regarded not as a fine art, but as *par excellence the* fine art. A liberal education necessarily implied a longer course of study than was usually given to architectural students. It would prevent many from entering so early into practice for themselves. Under the present state of things a man considered himself turned out a finished architect long before he was properly fitted for the work. Great as was the value of literature to the architect, it must not be supposed to take the place, in the very smallest degree, of the study of existing architectural remains. It must be regarded only as a golden lamp by which to read the lesson taught by such remains. The student must carry with him an intelligent and appreciative mind, as well as pencil and paper, to enable him to listen to and learn from the true though silent eloquence of the old work. But he must make himself well acquainted with every form of preceding art by reducing it to line and shadow upon paper, for the purposes of comparison and analysis. More might be done than had been to supplement the good which had already been effected by travelling studentships, by members associating together, under proper leadership and management, to work a given district in a systematic way. The amount of observation thus concentrated on one locality would give everyone the advantage of the inferences to be drawn and the lessons to be learnt from such study, and the results would be in many respects much more wholesome than those gained by the isolated study of such work by each member separately. It was not necessary to make foreign countries the first to be visible. It had been too much the custom to make a first rush to Italy, as the great nursery of the arts, as, in truth, it was. He (the president) would rather say:—Begin at home as a centre, and gradually extend your survey as opportunity serves. Let your tastes be formed at home; let your first impressions be derived from your national position and instincts, but let your knowledge be extended to the utmost limits accessible to you. A further source of mutual interest and improvement might be opened out, supposing the arrangement for it to be possible, if all members could be induced to produce their vacation studies at an annual meeting of the Association. A fund of information would be not merely collected, but disseminated, as to the existence and locality of works which were best worth seeing; it would extend our sphere of observation and study; it would give to us to some little extent the advantages of each other's ideas upon some of the most interesting features of preceding design; and it would be an additional inducement to take more pains to work out sketches in an accurate and intelligible manner by a comparison with what others do. I have now carried my remarks to too great a length to allow of entering into other topics of interest, to which perhaps I ought to have referred at length, such as the disputed authorship of the designs for the Houses of Parliament, the new works of the past year, the Law Courts competition, and the Architectural Exhibition, which latter is still carrying on successfully the work at which it aims. I can therefore only conclude by calling attention to the collections which have been kindly lent us for this evening's entertainment. I would especially mention the beautiful collection of needlework exhibited by a firm at Bruges, and also a new process for permanent and indestructible wall decoration. The process consists in placing the tiles together and then painting the subject, after which the tiles are taken apart and burnt, forming an enamelled surface. This enamelled surface when done on glazed tiles, such as those exhibited by Messrs. Lavers and Barraud, is capable of the highest delicacy of finish. The other specimen of the same kind, exhibited by Messrs. Harland and Fisher, on ordinary plain tiles, is capable of less elaborate finish, and it therefore forms a less expensive mode of decoration. The sketches by Mr. Phené Spiers and other drawings and paintings have, I hope, afforded an attractive portion of the evening's enjoyment.

Professor Kerr said that the discourse to which the members had just listened had been so full of subject for reflection that to dwell upon it in any degree at that late hour of the evening would be an impossibility. The Association had done good work in the profession of architecture, and was able, if fairly tried, to do good work still. When he said that, he meant that it might do even better work than it had yet done. His connection with the Association dated from the very commencement. The Association had probably done more in respect to the education of the young mind than any other society which the profession possessed. Certain it was that the Royal Academy and the Royal Institute of British Architects had a more stately designation, and fulfilled more stately functions; but he had always thought that this particular Association, being an association of young men for the exclusive purpose of promoting practical education amongst each other, was one which could not fail, had not failed, and would not fail to be productive of immense advantages. He had often said before that some of the cleverest architects—although not necessarily those whose names were the most prominent—owed to this Association their acquisition of cleverness of design. He was speaking of fifteen or twenty years ago. It would be out of place to mention names, but there were friends of his in the room who knew to whom he referred. He was sorry to find, however, that of late years the system of reading papers at the Association by members themselves had been on the decline. He could not imagine what could be the reason that this Association, numbering now 530 members, could not produce a dozen good papers in the course of the year. He could not help thinking that, if an effort was made, there were many in their midst who only required to be urged to produce papers alike creditable to themselves and the Association and the profession to which they belonged.

One of the secretaries handed the Professor the syllabus of papers, from which it appeared that more than half the papers were contributed by the members, and the Professor expressed himself glad to know this.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Inaugural Meeting, Session 1868-9.

On Monday evening last the inaugural meeting of the Institute was held at Conduit-street. The minutes of the last meeting having been read and confirmed, the deaths of Messrs. D. T. Alison and G. R. Burnell, Fellows, were announced. Mr. Menzies Marshall, of 22, Old Burlington-street, was elected an associate, and a list of recent donations of books was read, which included valuable contributions by Mr. Tite, in addition to his recent munificent bequest for the library.

THE PRESIDENT'S ADDRESS.

Mr. Tite, M.P., in rising to deliver his inaugural address, apologised for not having it prepared and printed as usual, pleading in extenuation the time occupied in electioneering matters. Concerning the Institute, he said that its success was manifest and increasing. The total number of associates, fellows, and honorary members in May this year was 623, and of fellows (the more important element) in 1858, they only mustered 146, but at the present time they mustered 262. This was satisfactory, inasmuch as it showed that the main element of the success of the profession in life was increasing. There were few architects in London who had not joined the Institute and endeavoured to further its objects. It was pleasing to find that the finances were satisfactory. During the past year the library had been added to in an infinitely valuable manner. One of the last paragraphs of the report of the council, dated May 4, contained the following passage, in which he heartily concurred:—"The council are glad to be able to report that the new arrangements with regard to the appointment of paid officers made during the previous session has worked satisfactorily, and the honorary secretaries have been thereby relieved from the more onerous duties of the office, and have, in consequence, been able to give attention to many matters which have previously been left in abeyance." Though in the early days of the Institute Mr. Fowler worked exceedingly hard, the business of the Institute so greatly increased that no one actively engaged in professional pursuits could be expected to find time to give attention to the work. During the past session the papers read, though few in number, had been of very great interest. Mention might be made of that by Professor Ansted on the relations between geology and architecture, and also that by Mr. Digby Wyatt. The discussions which followed these papers were very important. The last paper was that by Mr. Charles Barry, which dealt with the improvement of structural architecture, as exemplified in Dulwich College, by the use of terra cotta. Having had some experience in the use of terra cotta, he (Mr. Tite) would caution his hearers as to its employment. Where terra cotta was used in the ante-fixæ of the great church of St. Pancras it failed in a good many instances. Again, the statue of the Prince of Wales at Brighton, composed of this material, now presented a pitiable spectacle, one arm and one leg having fallen or been broken off. Young architects should be extremely careful that the material was well and homogeneously burned, and in introducing a new material of that kind they ought not to be too ready to adopt that with which they had not an entire acquaintance. Referring to the great competitions for the National Gallery and the new Law Courts, he said that the many incidents in connection therewith were of the greatest importance to the profession, and he would, therefore, ask the secretary to read short summaries of the entire proceedings in these two competitions. [This having been done, the President proceeded.] In Mr. Beresford Hope's inaugural address to the Institute the year preceding his (Mr. Tite's) nomination to the presidency, he made the following remarks:—

> I was just observing that there were certain complications attaching to the competition for the New Law Courts. These were of an administrative character, and owed their origin to the fact that the Government had handed over no inconsiderable portion of the control (which in the case of most public buildings would have been shared between the Treasury and the Board of Works) to a special commission, created by Act of Parliament, and comprising a large infusion of the legal element. These gentlemen set to work with a very sound principle strongly before them, and, as was not unnatural, rode that principle a little hard. They assumed that the successful architect (or architects) ought to have made himself practically acquainted with the working of the different courts of law, and the inference which they drew from this undeniable proposition was that it was needful for them to be excessively restricted in the number of competitors chosen, in order to prevent the business of the courts from being interrupted by the frequent visits of curious investigators, and so they drew the line at six. This was palpably in the eyes of all men, except the Commissioners themselves, an extravagant application of their principle. Not to allude to any other objection this restriction manifested considerable confusion as to the artistic obligation, contracted with the national honour, to produce the best obtainable building. However, it required a vote of the House of Commons to overcome the reluctance of this most respectable junta.

What Mr. Hope then predicted followed exactly. At the same time, the result, on the whole, was not unsatisfactory. The calling in of two professional judges—men of the greatest possible eminence and practical skill—was exactly the course to remedy the difficulty, and the appointment of Messrs. Pownall and Shaw was satisfactory to all. It was said that the plan of Mr. Barry and the elevation of Mr. Street were the best. These two gentlemen, by putting their heads together to erect the building, would have satisfied the nation and acted upon a principle for which there was plenty of precedent. But

such was not the result. Discussion was indulged in, and ultimately Mr. Barry was awarded the building of the National Gallery and Mr. Street the New Law Courts—a result which did not appear very much to please anybody, and which appeared so extremely difficult to consider, because each gentleman had equal merits, and the solution which he (Mr. Tite) ventured at the time to suggest to the House of Commons appeared a reasonable one. That suggestion was made on the motion of Mr. Julian Goldsmid, and was as follows:—That inasmuch as it was perfectly well known that the Law Courts as designed would occupy much more space than that accorded them, they should be divided, one to be located on the Thames Embankment, and the other in Lincoln's Inn Fields, and that the one should be entrusted to the care of Mr. Street and the other to Mr. Barry. That suggestion was opposed in the House, and thus the matter ended in a somewhat unsatisfactory manner. He was unwilling to pursue the subject further, except to say that unless the strictest adherence was kept to the conditions it was hardly to be expected that men of honour and talent would join in such competitions. The result might be satisfactory in the present instance, for one or the other of the gentlemen concerned would be sure to erect a creditable edifice. At the same time, if there was no disappointment on the one hand, nor inconvenience on the other, he should still regret that some more satisfactory result had not been obtained. If competition was to be indulged in, it ought, it must, and it would be done only successfully, usefully, and wisely by the strictest obedience to the original agreement under which gentlemen went into these competitions. Turning to another subject, he congratulated the Institute on having obtained the valuable assistance and friendship of Mr. A. H. Layard, who purposed during the session giving a paper upon the "Art Decorations of Venice." In an address of his (the President's) in 1862, he said that in the House of Commons architects were not particularly well received. At present they were held in much greater estimation. He would strongly recommend young architects not to confine themselves to one style. It was of no use being merely a Gothic or a Classic architect; but an effort should be made to understand both styles They should not be led away by the mere fashion of the day. The difficulty of the present day was that everything must be Gothic. Gothic was excellent when well applied, but it was not very agreeable when not so applied. This style was carried a little too far in the present day. He had done as much in the Gothic way as most men. He was one of the first men who attempted a railway station in that style. Whether he had succeeded or not a visit to Carlisle would decide. It didn't go very well with the platforms and roofs, but very well indeed with the interior and the refreshment rooms. He congratulated Mr. Scott upon the development of that style as witnessed in the new Midland Railway Station at St. Pancras. One could not sufficiently admire the skill displayed in the construction of the roof, as also the propriety of the decorations belonging to it. It was a building in every way worthy of the nation and the time. He would now advert to a subject upon which it was painful to dwell. One of the deaths announced is that of Mr. G. R. Burnell, who was a great personal friend of his (the President's). He was well known as an architect and civil engineer of several great undertakings, and made his mark in the ranks of professional literature as a profuse and accurate author. Amongst his other works he contributed important series of articles to the BUILDING NEWS, principally upon roof construction. After briefly alluding to the death of Mr. Alison, Mr. Tite referred to the Thames Embankment as a work worthy of ancient Rome, and of which Englishmen might well be proud. That work had been carried out so far in a comparatively short time, but whether regarded from the beauty of the material, the excellence of the workmanship, or the utility of the work itself, it marked itself out as one of the greatest features of the age. Powers had been recently obtained for its continuance up to Battersea, and probably efforts would be made to continue it on the other side. He was gratified at the progress made in the new St. Thomas's Hospital, opposite the Houses of Parliament, which was being erected from designs by Mr. Currie, upon the plan of the Lariboisière and other great French hospitals. It would accommodate 600 sick persons, and as a piece of architecture would be just as creditable as it was as a work of humanity. After an allusion to the progress of architecture in the City, the President said that he recollected the Bishop of Oxford speaking some three or four years ago in the Egyptian Hall of the Mansion House on the subject of the re-decoration of St. Paul's. He said that he had been looking at Evelyn, who stated that "he had passed through London, and thought it the ugliest city in all Europe for its size." He (Mr. Tite) hoped that we were removing the great blot on our national education and means, and that soon we should have London worthy of the great nation of which it was the capital. He could not say quite as much for the bridges which were now spanning the Thames in all directions. Old Blackfriars Bridge had ceased to exist, and of the structure now taking its place he might apply the words of Evelyn, and say that it would be the ugliest bridge in all Europe for its size. However, it would bring increased convenience, and add to the comforts of Londoners. In conclusion, Mr. Tite thanked the members for their attention, and for the honour they had conferred upon him in electing him to the post of President.

Mr. BERESFORD HOPE, M.P., in moving a vote of thanks to the President for his address, paid a high tribute to his personal merits, although he could not endorse all that he said. He would, however, say that he thought the constitution of the Institute very peculiar, inasmuch as the mover of a resolution could not vote thereupon, and were any so wild as to get up and move a counter proposition to that which he had put forward, he would, by the rules of the Institute, be unable to support his own motion. He thought it time that a reform should be effected in certain matters connected with the Institute. Then, again, there was another rule, worthy only of four hundred years ago, relative to memberships and fellowships of the Institute. £25 made an honorary fellow, and architectural eminence only made a member, so that in the opinion of the Institute £25 was of more value than architectural eminence. If the profession was to be honoured and respected, reforms must be effected at the Institute. As to competition, how was a young man to make his talent known without it? Those who decried competition should at least be able to bring forward some other plan by which the interests of all would be served. In reference to some question concerning the profession which he was to have brought before the House last session, he said that he had not done so for several reasons; but, if returned to the new House, he intended to introduce the question as a branch of a more comprehensive scheme—viz., the appointment of a public Minister of Art, Architecture, and Science, who should absorb the offices of the First Commissioner of Works and other officers—a minister who should be responsible to Parliament. He agreed with the President in saying that it was the duty of the architect to study all styles of art.

Mr. G G SCOTT seconded the resolution, saying that so far as he was personally concerned he was satisfied with the results of the competition, and he thought he spoke the general feeling of the profession.

Mr. GEORGE GODWIN, in support, said that while it was advisable to let bygone competitions be bygones, he must remark that there was at present a great number of competitions which appeared to be managed in a very remarkable manner. He especially alluded to those for erecting asylums in the metropolitan district for the imbecile poor. He wanted to know who named the six or twelve gentlemen who were selected to compete. In one or two cases at least the best that could be said of the young men brought into these competitions was that they were untrammelled by anything like former work or former connections, and would make their *début* as architects of these asylums. Some of them would doubtless distinguish themselves, but older men should not be passed over.

Mr. CHARLES BARRY suggested that the architects of the asylums referred to were selected from motives of economy. The terms offered were such as no member of the Institute could conscientiously accept. The subject of competitions was, however, under the consideration of the council.

Mr. A. H. LAYARD, M.P., in supporting the vote of thanks, referred to the fact that the Government was about to erect the largest series of buildings that had ever been undertaken at one time. These comprised the new Law Courts, the National Gallery, a greater portion of the public offices, and a building in the neighbourhood of South Kensington for the natural history collections of the British Museum. He would offer no opinion as to whether these buildings should be in the Gothic or in the Classic style. He wished that those words were forgotten, and that attention was turned more to the cultivation of a true English style. It concerned the national honour that these buildings should be erected in a style and in positions worthy of us. They had a magnificent site in the Thames Embankment, and opportunities were now afforded of erecting a series of public buildings unequalled in grandeur by those of any other country. He trusted that the Institute would direct particular attention to these buildings with a view to prevent the perpetration of errors. The decision of the House of Commons concerning the National Gallery had not been satisfactory, but it was idle to think of altering it now.

Mr. BERESFORD HOPE put his motion, which was carried by acclamation.

The PRESIDENT, in responding, said that the Royal Academy would be ready to receive the pictures in April next, when a large increase of wall space would be given to the profession.

Mr. PARKER briefly called attention to the proceedings of the British Archæological Society at Rome, after which the meeting adjourned.

ASSOCIATED ARTS INSTITUTE.

THE opening *conversazione* of session 1868-9 took place on Saturday evening last. The walls of the room were adorned with many fine paintings and sketches, and in the way of statuary Mr. W. Whale's group, "The Slaughter of the Innocents," for which the last gold medal at the Academy was awarded, and a bust of the poet Montgomerie Ranking (who is a member of the Associated Arts Institute), by Mr. F. Scarlet Potter (one of the secretaries), were exhibited. Some sea pieces, by Bellamy, and some fine sketches, by Mr. R. Phené Spiers, attracted much attention. Particularly noticeable, however, and forming a principal feature in the proceedings, was the exhibition of a series of water-colour sketches of exteriors and interiors of old abbeys, castles, churches, and mediæval buildings, the productions of the late Sir Richard Westmacott. These were much admired, and allusion was made to them in the president's opening address. Madame Talbot Sherer, and other ladies and gentlemen, tended greatly to the evening's enjoyment by displaying their musical abilities.

Professor Westmacott, the president, in commencing his address, said that an opinion might now fairly be given upon the condition and prospects of the Institute, seeing that it was now in its fifth session. He was very glad to say that these were very promising. They must all be aware of the difficulty of organising new societies, more especially when they had so much in relation to others that already existed, and the only advantages to be gained by the creation of a new institution of the kind was to give it some specific distinction. The purpose of this institution was sufficiently distinct to warrant the promoters of it in carrying it out as they had done. That purpose was to direct artists in all branches of art—painting, sculpture, architecture, and engraving; to lend its assistance to the furtherance of all schemes which were of general interest to all engaged in the pursuit of art, upon the principle that though every branch of art might be practised separately, each of its particular sections tended to a perfect whole; and, taking this view, the communication of ideas and the interchange of opinions might lead to results which should produce those harmonious wholes and combinations which all the arts together ought to effect. That was no new or impossible or Utopian theory, because they knew from existing examples that this union and combination of artistic opinion had already been very successful, and had led to great results. More especially did we see this in the best periods of Greek art, which embraced a system of beauty which had never before existed in any other school. Art, as they all knew, was far too difficult for it to be supposed that individuals could, as a rule, excel in every branch. There had been, however, remarkable instances where excellence had been attained in several directions, such as Michael Angelo, Raphael, and others. Bernini was an artist who had a great mind for combinations, and produced very remarkable works. It was told of him that in his time a fête was given in Rome, when he designed the theatre, painted the scenes, wrote the drama, composed the music, and executed the

statues for the staircases and the difficult parts of the building. Although Bernini's works were not such as could be put before artists as examples, he was possessed of remarkable power, and such a possession was a rarity. It must be admitted as a depressing fact that out of the thousands and thousands of persons who devoted themselves to the pursuit of art, very, very few were able to leave works behind them which would live. But this fact in itself placed art in a very high position, for it showed that it was impossible to give too much time to it if excellence was sought to be attained. It was almost impossible for any individual to hope to excel in all branches, seeing that it required the whole energy of a lifetime to excel in one. It was not unnatural under these circumstances that young men especially should endeavour to organise some system by which they and their brethren might talk together over the difficulties of art. With such an object this association had been formed. They ought to feel, and they must feel, that those engaged in particular sections of art ought to work in concert, and to show that although every individual had to attain excellence in his own particular branch, all those parts were parts of one whole, leading to one great result. Those who knew anything about the history of art knew that such combinations of artists as that institution existed in mediæval times in the guilds and brotherhoods of art, where individual feeling was absorbed into association, and self was lost sight of in a corporation. The results of this association and abnegation of self were seen in some of the great works on the continent even now. The artists sacrificed their own views in order that some great purpose might be carried out. They sacrificed at this shrine of combination all personal feelings of jealousy and greed of gain, which had often seriously diminished the strength of art. He thought that it was precisely this want of the renunciation of self that characterised the art of the present day. It had this advantage, certainly—that we saw a great deal of originality in art, arising from each artist pursuing the bent of his own inclinations; but they must all admit that there was a great want of association in art in all that they did. If a Greek architect was required to execute a great work, the Parthenon for instance, he called to his aid all the resources of this principle of combination, and the artists of the middle ages worked in precisely the same spirit: and that it was that produced the art of those periods. Although there were prejudices which arose against societies of that kind, it was but fair to state how the Institute guarded against them. It was thought in some quarters that these associations very often ended where they began—in talk. The Institute was not a debating society. Its members never met until their work of the day was finished, when they met to exchange opinions. There was no objection to this, provided that the members guarded against any abuse of it. Throughout life people were met with endowed with different gifts; and in a meeting of that kind were to be found many gentlemen who could literally give valuable information to their friends from their own practical knowledge of art. There was another class of members who had time and opportunity to study the literature of art, and another class who had been in the habit of studying the canons of criticism. From all these various classes of members which the Institute embraced much was to be learnt, for there was no single intellectual exercise that might not be brought profitably and advantageously to the service of art. There was another peculiarity in that Institute which was highly creditable to its founders; it held out its arms to give a welcome to amateurs, and was only too glad to show that there was no petty professional exclusiveness that could shut the door against anyone who as a student of art was eligible for membership. Mr. Potter, the secretary, had furnished him (Professor Westmacott) with some statistics which showed that the Institute was in a healthy state. The present was the fifth session. At the opening in 1863-1, the number of members was 9. Now, in 1868, the members numbered 114. There were few societies that made such small calls upon the powers or the time of artists that could be said to show greater signs of vitality. The subscriptions of the members, though only 5s. per annum each, had been more than sufficient for the wants of the Institute. It was, however, proposed to increase the amount of the subscriptions, not with a view of making a purse, but it had been thought that when artists of distinction or experience were so kind as to address the members and give them discourses on art or on subjects connected with art, it might be advantageous, with the new means at the disposal of the Institute, to have these printed and delivered to the members. There was another reason why it would be desirable to record the proceedings of the Institute. In case there should be any members who attended only to hear their own voices, they might be a little deterred from making long speeches from the fact that "there's a chiel amang them takin' notes, an' faith he'll prent it." The meetings would, for the future, be held fortnightly, and papers upon art subjects would be read at alternate meetings only. There would be an exhibition of sketches once a month, from subjects announced on the programme of the Institute. Elaborate drawings were not expected, although true artists would, of course, send in nothing but works of art. On the evenings of these exhibitions there would also be discussions upon questions bearing upon and influencing the growth of art. In conclusion, the Professor adverted to the series of sketches (sixty in number), by the late Sir Richard Westmacott, which he had had great pleasure in lending for the evening. They had never before been publicly exhibited, but when it was considered that they were the works of a sculptor he felt no shame in showing them, for there were few men who could produce such a series of sketches. An eminent architect had said that they were remarkable for the breadth of treatment which characterised them—breadth of treatment in an art (architecture) which their author did not profess.

NEW CHURCH OF ST. LUKE, MILLWALL.

THE new Church of St. Luke, Millwall, of which we give a view and plan in our present number, is the development or rather fructification of the work of the Mission established in the district of the parish of Poplar, and which has been in operation for the last three years with the most beneficial results. Hitherto the services of the Church have been performed in a temporary building situate in the West Ferry-road. This will presently be superseded by the new and permanent church now in course of erection on a site adjacent, given by the Lady Margaret Charteris. That lady has further assisted the work by a liberal money contribution, in which she has been followed by many other well-wishers to the undertaking.

The new church, which is from the designs of Mr. E. L. Blackburne, architect, of Bernard-street, Russell-square, is calculated to afford accommodation for 600 adults, all upon its floor space. Its style is an early phase of the Pointed Gothic. Its plan comprises a chancel, having a vestry with porch, &c., on the south side, and an organ room on the north, respectively marked D and C on the plan; a nave and north and south aisles, with tower and spire at the east end of the former; and an ambulatory and porch at the western end, marked in like manner B and A on the plan. The materials employed are Kentish rag stone random-laid, with coursed bandings of the same for the exterior face of the walling, and stock brick, relieved by yellow malms and white Suffolk bricks in the arches and stringcourses, &c., for the interior. The freestone work for doors, windows, nave columns, and arcades, &c., will be the best Bath and Ancaster stone. The roofs and other portions of the timber work will be clean deal, varnished. The seating and other similar furniture will also be of clean deal, varnished. The pulpit and reredos will be of stone, the font, of course, the same. The floor of the chancel will be paved with ornamental tiles, as will also the nave and aisle passages, &c. Such parts of the area as are covered by the seats will be boarded. The windows will be glazed with tinted cathedral glass in quarry patterns. The roofs will be slated, and the ridge finished with an ornamental cresting in tile. Mr. Howard, of King-street, Covent Garden, is the contractor for the whole of the works.

NEW METHOD OF LAYING TIMBER IN ASPHALTE.

IN the annexed cuts, in figs. 1 and 2 we have a longitudinal section an elevation, and a cross section of a new method of laying joists and other timbers in asphalte or bitumen. The invention has been recently patented by M. Rigoulot, the object being to ensure a greater degree of solidity, with a less expenditure of labour. The timbers intended to be laid down upon the substances mentioned are in the first place grooved longitudinally by machinery upon that face which is intended to lie upon the asphalte. The groove in cross section (see fig. 2) represents a swallow's tail,

FIG. 1.

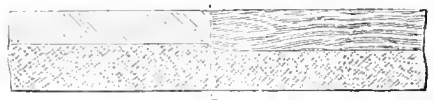

FIG. 2.

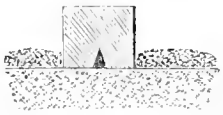

and the consequence is that when the wood is placed upon the hot bitumen, the latter penetrates and fills the groove, affording a great increase of support and strength to the timber. Half of fig. 1 represents a longitudinal section of a joist, showing the bitumen filling the groove, and the other half an elevation. Another advantage of this method is that it dispenses with all nails, screws, and other fastenings. Moreover the wood can be laid with greater rapidity than under the ordinary system. There is, of course, the cost of grooving the wood to be taken into account, but this is more than counterbalanced by the saving in labour and materials.

READING DESK AND CHAIR, CHAPEL NESTFIELD, DARLINGTON.

THE chair and reading desk which with details forms the subject of one of our illustrations was designed by Mr. G. G. Hoskins, of Darlington, for the United Methodist Chapel at Nestfield, Darlington, which building has just been completed from his designs. The furniture is of red deal, with pierced sides and ends, and stained and varnished, the chamfers being stained a darker tint than the rest of the work, thus causing the mouldings to stand out in bold relief. The cost of the chair was £6 6s. 6d., and the desk £5 11s. 6d.

NEW STEAM GENERATOR.

THE *Leeds Mercury* has pleasure in drawing attention to a new steam generator, in the using of which explosions are entirely obviated, and where, moreover, economy of space is a desideratum, its compact and portable form must ensure its speedy adoption. We refer to the new patent boiler and superheater, by the well-known firm, the Messrs. Howard, of Bedford. Two of these boilers, now working at Messrs. Illingworth and Ingham's, timber merchants, Wellington-street, we have seen. They are tubular, commencing over the fire with a series of horizontal tubes, a vertical series rising from these joins to another horizontal series at the top; these latter and top of the former becoming the superheater. The bursting pressure of each of the tubes is at least 2,000lb. to the square inch, and tested to a bursting pressure of 500lb. to the inch. In the event of the bursting of a single tube (a very unlikely occurrence) no dangerous accident could ensue, the result being only equal to the opening of a valve, with a rush of steam and water into the heating chamber, a sudden lowering of the steam pressure, and possibly the extinction of the fires. The two boilers are each 35 horse-power nominal, or collectively 70 horse-power, and only occupy a space of 12ft. by 10ft. by 6ft. 6in. Priming, the original evil connected with this principle of construction, has been entirely overcome, and the evaporative power of the boilers is something uncommon, 11lb. of coal evaporating 10lb. of water. A working pressure of steam can be generated from cold water in twenty minutes from the time of starting the fires. So that apparently from every point of view this invention seems successful.

At Nottingham a Board of Arbitration has been formed of six master builders and six operative joiners as arbitrators, and an architect as umpire. The president is a builder, and the vice-president an operative; and one of the secretaries is a builder, and the other an operative. The other branch trades have not yet fallen into the plan.

SMOKEPROOF ARCHITECTURE.

IN prospect of the erection of the new Law Courts, some of the daily papers have very properly insisted on the necessity for using such building materials only as will resist the action of a London atmosphere. There must be no repetition of the lamentable failure at the Houses of Parliament. But this is not all. It is not enough that our chief national works should be free from premature decay if they are still liable to be blackened and defaced almost beyond recognition. Of what use is it to select costly stones, and fashion them with infinite labour, when a very few years will hide every tint and every detail under a veil of soot? Design is almost wasted under such conditions, and elaboration is fairly thrown away. Three-fourths of the money spent in ornament on our new City buildings would have been laid out to far better purpose in improving the materials with which they are built, and thus making their design a permanent instead of a transitory thing. Under these circumstances some of the journals above referred to have advocated the extensive use of terra cotta: and the relative merits of this and some other substances may be worth examining. With regard to durability, terra cotta seems to vary considerably. It has certainly acquired a high reputation, but this is chiefly based on its performances in more favourable localities than London. The very best description may probably prove more durable than most kinds of stone, but the inferior ones—as anyone may see at some of the stations of the Metropolitan Extension—begin to scale off and disintegrate after a very short exposure to the air. On the effects of frost, supposing water to find its way into the interior of hollow terra cotta blocks, it is needless to dilate. This is a source of failure which care might prevent, though care of this kind is not always certain to be employed. The unpleasant variations in colour to which this material is liable form a more serious failing. Nothing is more common than to see, in the different blocks which make up one feature, all shades between white and reddish brown, the whole vividly recalling the different stages of baking exhibited by the loaves in a shop window. By more caution in burning, and more firmness in the rejection afterwards of bad specimens, this evil might be diminished, of course with a corresponding increase in expense. But the fact remains that under no circumstance is terra cotta equal in colour and texture of surface to good stone. It is unfortunate, therefore, that manufacturers should still attempt to make it an imitation of stone. Red would be a better and more characteristic tint for it than the dirty white which is most usual; but red terra cotta is at present rarely used.

Our object in noticing these weak points is by no means to discourage the use of terra cotta generally. Difficulties of manufacture may be and doubtless are being surmounted. Ancient buildings in abundance show how much may be effected with the material in question; and several modern ones, including the new Courts at the Kensington Museum, owe much to its introduction. It is, in fact, the highest form of brick decoration. Terra cotta dressings are to a brick building what freestone dressings are to a rubble one. And as brick is the natural groundwork for the great bulk of London architecture, terra cotta is extremely appropriate for its ornamental features. It needs to be used with care, for it lends itself with unfortunate readiness to that love of display which is the canker of modern art. There is the disheartening prospect of seeing the same details used over and over again to weariness, till what was striking and effective at first becomes thoroughly sickening by repetition. This, after all, is the great danger to be guarded against when terra cotta is introduced into our street architecture; and architects will be wise to avoid cast ornament and to have the chief points of their work modelled. But, to follow more closely our main subject, Will terra cotta resist the action of smoke? The truth seems to be that its power of doing so varies greatly according to its quality; that in nearly every case soot will adhere to it, but not in such a way that it is incapable of being washed off. This is an improvement, so far, on Bath or Portland stone, and it is something to have buildings that may be restored—for a month or two—almost to their pristine freshness whenever the proprietors will go to the expense of having them cleaned. But this, it is to be remarked, is a very different thing from having buildings that remain always bright. Our present blackened structures of Portland stone might be washed into a mitigated shade of brown if anyone cared to do it. The late cleansing of Temple Bar shows how much might be done in this way, and yet there stand City churches and halls in such a state that one could hardly say whether some parts of the walling were originally of chalk or coal.

Terra cotta, then, seems worthy of far more extensive use in our street architecture, but it is after all a material for second class rather than for first class work. Both in colour, texture, and excellence of workmanship, good masonry will always remain superior to it. But it has, or ought to have, two advantages over ordinary masonry. It is less liable to decay, and more capable of being cleansed. Is there, however, nothing that will combine these properties with those that are wanting? One need not look far for a reply. Without going beyond the limits of the British islands, we have an abundant supply of marbles and granites, of almost any colour, which can be so far polished as to resist all adhesion of soot, and which are all but unassailable by decay. Some of them are extremely beautiful, and their beauty, unlike that of common stone, could be lasting and unalterable. It is true that they are costly to work: permanence always involves labour, but what is once executed in them will remain. And, after all, which is the most extravagant—to put a given amount of workmanship where it will be practically annihilated in a year or two, or to put double the quantity where it will last unimpaired for century after century? A country as rich as England can surely afford to build its public works, not for ephemeral display, but for permanent use and grandeur. But it is not so much a question of more money as of more wisdom in laying out the money. The Houses of Parliament, now blackening and decaying before our eyes, might have been built of granite and marble for the sums spent to fritter away their surface into panelling. If the use of durable materials did nothing but check the eruption of meaningless ornament now epidemic, it would be well worth advocating. Mr. Ruskin says somewhere that there would be more good painters if colours were a guinea a cake; and on a similar principle, there might be more good carving if carved cornices were a guinea an inch. Architects and sculptors, too, would then put a little more thought and purpose into what was to be paid for so dearly. And if the style of building here suggested—the only one at present known which smoke and dirt will not deface—should have the trial it deserves, it can hardly fail to cause a most healthy reaction in our architecture. People would then think twice before inserting elaborate features, which, like a great many commonly adopted, are neither useful nor ornamental. Designs would become, so to speak, more terse, more concise, expressing more than now with much less apparent effort. They would gain in "temperance," and therefore in force, and so would become worthy of the permanence which their materials would confer.

The subscription for Leigh Hunt's tomb is sufficient for the purpose, and Mr. Durham will at once proceed to finish his design for it.

NORWICH BOROUGH LUNATIC ASYLUM.

THE Corporation of the city of Norwich some time since invited Mr. Brown and Mr. Phipson, architects, to send in plans for the new Lunatic Asylum which they intend to build. This was done, and the council have at length, acting on the report of the select committee, who were mainly guided by the reports of Drs. Robertson and Campbell, selected those submitted by Mr. Phipson. The building, which will probably be shortly commenced, will cost £33,000, or about £5 per head. Mr. Phipson's design is a combination of the pavilion with the old system, and his description states that the building will not pretend to any architectural effect.

MODERN GASWORKS AT HOME AND ABROAD.

ON Monday evening an elaborate paper on this subject was read at a meeting of the Society of Engineers by Mr. Henry Gore, consulting engineer. Among the varied applications of scientific discovery to the purposes of daily life, few, if any, have obtained greater importance than that which relates to the manufacture of coal gas. Scarcely a city, town, or village of considerable size in this country, on the continent, or in the United States of America, remains unsupplied with this indispensable agent in our industrial and social existence. Its use is rapidly extending in more remote regions, for, strange as it may appear, there are many peoples and communities who, though persistently resisting useful applications of practical science as dangerous innovations, are yet eager to avail themselves of the use of gas as a source of artificial light and heat. Even religious prejudices of the most obstinate character have succumbed to this desire, and we now behold the Christian church, the mosque of the Mahometan, the Hindu, Buddhist, and even the Chinese temple, each illuminated by this simple yet beautiful light.

In the earlier years of gas-lighting the illuminating power of gas was not regarded as a question of any great importance. The coal or material most easily or cheaply obtained was used, so that rich or poor gas was produced just as the works happened to be nearest to ordinary or cannel coal. When opposition was raised to the companies, it was always on the ground of price. Opposition to high prices led to the establishment of the Great Central Gas Company for supplying the City of London. The two fundamental principles upon which this undertaking started were a low price and a low standard of illuminating power.

To carry these proposals into practice required that the works should be constructed upon a system involving some important modifications and changes in the machinery and apparatus: and a process of manufacture was adopted, the main feature of which was to obtain quantity, quality being only a secondary consideration. The principle laid down in the case of the Great Central Company has been more or less applied throughout the country, and the result has been that the constructive details of gasworks have been carried out almost exclusively with a view to obtain the largest possible quantity of gas from the materials used for its production. Furnaces affording the greatest heat, retorts exposing the largest carbonising surface, condensers and scrubbers making the strongest ammoniacal liquor, purifiers of large capacity and surface for the oxide system of purification, monster gasholders, and last, though not least, street mains of the dimensions of small tunnels—these, and perhaps some other matters, are the concomitants of cheap gas as introduced at the period above referred to. Subsequent events, however, have shown that the consumers have become dissatisfied with their bargain. An agitation which originated some years ago still continues for a repeal of the condition as to quality, and the legislature has so far interfered as to raise considerably the standard of illuminating power; the important question presents itself whether, in meeting this change, it may not be requisite to modify the present mode of constructing gasworks, especially in those localities where mixed coals are used for producing gas of the quality required by these new regulations.

In large works, and with clay retorts, the system of through setting with double mouthpieces is unquestionably the most economical both as regards fuel and durability. But this arrangement is open to grave objections. If the

retorts are used for the generation of gas of high illuminating power, the increased surface over which the gas passes after it is eliminated from the coal exposes it to the chance of decomposition and the consequent deposition of its carbon. That this goes on to a very great extent is evident from the amount of solid carbon or graphite found on the inner surface of the retorts. In through retorts this deposition is due mainly to two causes; in the first place, in charging the retort with coals either by the scoop or shovel, the centre of the retort scarcely ever receives its due portion of coal, and as this part is always the hottest it follows that the gas generated from the thinner stratum of coal is exposed to intense heat, and a portion of it is speedily decomposed, liberating the hydrogen and depositing the carbon, thus forming a deposit which rapidly increases and soon renders the retort useless, unless precautions are taken from time to time to remove the carbon. Another cause of this deposit is the want of uniformity in the pressure in the two hydraulic mains; a slight resistance in one main or the other causes the gas to take the course offering least obstruction, and as the particles of gas thus pass over a larger amount of heated surface, they are exposed to the greater risk of decomposition. Several expedients have been suggested to remedy this evil; one is to use a valve to each ascension pipe so as to dispense with the dip pipe when the retort is working; another is to have only one hydraulic main placed over the centre of the ovens and both mouthpieces connected to it by a single dip pipe. The material of which the retort is made will exert a very important influence on the production of gas of high illuminating power. The high temperature at which clay retorts are worked tends to produce a very large quantity of carbonic oxide and hydrogen, by the decomposition of the olefiant gas and hydrocarbon vapours. It is frequently asserted that by the use of richer cannel coals the excess of non-illuminating gas is rendered highly luminous by becoming saturated with the hydrocarbons given off from the richer coal; but this is only true to a limited extent, inasmuch as the mixture undergoes rapid deterioration, consequent on the liquefaction of a large portion of these hydrocarbon vapours. The two forms of condenser most generally in use are the tubular, or series of pipes, and the annular. Whichever of these forms is adopted a large extent of surface is indispensable, in order that the separation of the mechanical and non-chemical impurities contained in the crude gas may be gradual. In the generality of works as now constructed, the gas, after leaving the condenser, is subjected to the process of washing, either by means of the old-fashioned wash vessel or the modern contrivance called the scrubber; the object in either case is still further to purify the gas from any remaining particles of tar, heavy oils, and ammonia. Many very conflicting statements have been made in reference to the effect of water in removing some of the light-giving constituents from coal gas. Several chemists have asserted that water exerts but a small influence in diminishing the illuminating power of coal gas. Some engineers, on the contrary, say that water produces a very injurious effect.

On the first establishment of gasworks some very absurd opinions were expresed as to the form, construction, and capacity of gas-holders. The restrictions proposed as to the dimensions of these vessels are certainly very amusing when recalled and contrasted with the monster creations of the present day. The demand for gas, consequent on the reduction of price, has led engineers to construct gas-holders the capacities of which are measured by millions instead of hundreds of thousands of feet, as was the case formerly; attempting to answer satisfactorily the ever-recurring question of economy. The larger the gas-holder the cheaper its cost at per thousand feet of its contents; but it is a question for serious consideration whether, as a matter of safety, these enormous depositories are not open to grave objections. So long as the quantity produced in the course of manufacture was the essential object of our manipulations, the effect on the quality of gas by its storage was only of secondary importance; but if, as we are by recent events led to believe, a much higher standard of illuminating power is to be imposed on gas manufacturers, the advantage of these enormous gas-holders may not prove so obvious in the future as they appear at present; for, besides other reasons that will suggest themselves to the mind of every competent gas engineer, the fact that the storing of gas (especially such as contains any considerable amount of hydrocarbon vapours) is sure to result in an appreciable diminution of its illuminating effect is, of itself, a good ground for objection against the construction of injudiciously large gas-holders.

In selecting a site for works, the following are among the most essential desiderata:—Sufficieney of area, a low level, a good supply of water, good drainage, and easy access. Even in some modern works these important conditions are sometimes most palpably neglected; as a general rule, however, they are complied with. In the earlier times of gas engineering it was thought desirable that the supply should be as near as possible to the centre of the consumption, but modern practice removes our gasworks to remote distances, and some enthusiastic persons have even suggested the removal of the manufactories to the centres of our coal districts. Wild as this proposal seems, it might possibly be realised if *gas* and not *light* was the product to be supplied; but if the public demand *gaslight*, and not *light gas*, then the proximity of the works to the locality of the consumption must be a vital element in the economy of gas manufacture. The longer the distance through which the gas has to travel before reaching the burner of the consumer, the greater will be the loss of illuminating power; hence it follows that a company supplying gas from works three or four miles from the district or place where the gas is to be consumed willl have to use a much larger proportion of canne or other light producing material to produce and supply gas of equal quality with a company only a mile from its consumers. It is very questionable if the advantages said to be gained in a sanitary point of view, or the greater economy effected in the delivery of raw materials, and the distribution of residual products, as coke, tar, liquor, &c, will at all compensate for the increased outlay in mains and the attendant loss of illuminating power.

In designing gasworks for new countries, it is a great error to be guided solely by home practice, especially in reference to retorts and furnaces. The number of retorts in a setting should never exceed five, and, even in the largest works, settings of threes should always be provided. The demand for gas in some of these countries is not at all uniform, especially in the case of public lighting; special festivals and the exercise of police and municipal authority frequently interfere to affect in an important degree the quantity of gas required. To meet such exigencies, it often happens that it would be better to light up two beds of threes than one bed of fives, or *vice versa*. Simplicity of arrangement in the setting of retorts is also of the utmost importance, so that the bricklayers' and other work may be performed by comparatively unskilled operatives. The employment of native labour is an essential element in the success of all gasworks abroad.

It is of the greatest importance in hot dry climates to keep the gas-holder cool during the hottest part of the day. It is the universal stipulation on the part of the gas companies that the public lamps shall not be lighted when the moon is visible, and the practice is to reduce the stock of gas in the gas-holder at such times as low as possible, consistently with safety, relying on the retorts to meet any sudden extra demand. During the summer or dry season, the evaporation caused by the heat of the sun's rays is so great that an immense quantity of aqueous vapour is formed in the gas-holder, which is carried forward by the gas into the mains and fittings, causing great annoyance and trouble. Painting the roof of the gas-holder white and several other expedients have been tried to get over this difficulty, but the only one attended with any success has been sprinkling the roof with water by means of a rose jet. Notwithstanding all that could be done, a very considerable amount of water is from time to time deposited in the mains and fittings, and it requires constant and careful attention to avoid inconvenience to the consumer.

For foreign gasworks, especially for warm or tropical climates, the author would suggest the desirability of the greatest simplicity in the design and construction of the requisite buildings, and the absence of all complication in the machinery and apparatus. The buildings, if not used as storerooms for valuable goods, should be merely roofed sheds, supported on iron or even wooden pillars. All enclosing walls should, as far as practicable, be avoided. Care should be taken to provide ample covering for coals, but with sufficient ventilation. An abundant supply of water is essential, with appliances for raising streams or jets to a considerable altitude. The tanks of gas-holders, if required to be made of iron, are better of wrought-iron than of cast, particularly in countries exposed to earthquakes. If the engineer is not well assured of the nature of the ground, he should shrink from designing a brick or stone tank for such countries. In laying street mains especial care should be taken to ensure a more than average depth below the surface, and a sufficient, but not too great, inclination or fall.

In carrying on the operations of a gas establishment in countries similar to those just described, the engineer will find his duties and responsibilities infinitely more arduous and onerous than those he would be called upon to discharge in the situation of a manager and engineer at home; it is therefore of the utmost importance to him that his works and apparatus should be as simple as possible consistently with due efficiency. Above all, let him employ to the utmost extent to which they are available the labour and the materials of the country. In doing this he may have to pluck up deeply rooted prejudices, probably to place in abeyance well-grounded opinions, the soundness of which he may have thoroughly proved under other but widely different circumstances; this he should be ready to do with cheerful alacrity and unreserve. Assuredly he is most certain in a foreign country to achieve success in engineering and manufacturing enterprises who acquires the most thorough knowledge of, and influence over, the inhabitants of the country, and masters most completely an acquaintance with the character and capabilities of its productions; who can enlist the hearty co-operation of the people, and lay the native products under contribution to subserve his purposes; who, in a word, most completely adapts himself to the peculiarities of the circumstances, influences, and objects which surround him in the new world in which he is placed.

SCHOOLS OF ART.

THE distribution of prizes gained by the pupils in the Oxford School of Art during the past year took place in the Townhall on Thursday week. More than the usual interest was felt in the proceedings, as the Lord President of the Council (the Duke of Marlborough) had consented to take the chair, and hand the distinctions gained to the recipients. In the course of his remarks the Duke said he hoped to see a greater number of schools taking advantage of those loans which were made from the Central Museum. There were about ninety-eight schools of art in this country, and he regretted to say that only twenty-one of them had availed themselves of the opportunities afforded in this respect. One advantage enjoyed by students in art schools was the grant of "aid" of £3 for "free studentships" in the artisan class. By a recent minute, an addition of £5 was also given for the payment of pupil teachers. A step in advance had also been made with regard to the payment of masters. The Department was really anxious in every way to promote the efficiency as well as the enlargement of its schools of art, and he trusted that not only the Government he had the honour to belong to, but succeeding ones, would have credit for their exertions, and that the money freely given would not be bestowed in vain.

Yesterday week the Mayor of Bristol distributed the prizes won by the competitors of the local school of art. The following is an abstract of the report which was read by the secretary:—The school is in a satisfactory position so far as the success of its students can be a test; nevertheless the debt of £655 and the decrease of annual subscribers continue seriously to fetter the expansion of the school. The annual examination of the second or elementary grade, was held on the evenings of the 12th, 13th, and 14th of March last, under the superintendence of members of the local committee, in accordance with the requirements of the Committee of Council for Art. The results of the examination, as awarded in London by the inspectors of the Science and Art Department, have been most encouraging. 111 exercises were satisfactorily worked; 16 students received prizes, and 7 obtained "full certificates" of the 2nd grade. The number of awards made to students of the school in the advanced stages amount to 13 prizes, and 5 honourable mentions; 19 works obtained the honourable distinction of being selected for national competition. It being popularly believed that the School of Art and Fine Arts Academy are one and the same institution, it is desirable to make it generally known that they are distinct and separate institutions; and as subscriptions are urgently solicited, it should be clearly understood that they are wholly devoted to assist in paying the working expenses of the night classes for artisans, who are taught at a nominal fee. The day classes are self-supporting, and do not benefit by any subscriptions in support of this school. The numbers in the day classes are 120; in the night classes or artisan class, 140.

The following is a hint for builders of new churches. We have from Valparaiso an extraordinary account of the election of a patron saint to one of the churches there, which was concluded on September 6. The *Mercurio* says the favourite candidate was "the Adorable Saviour of the World," who polled 19,946 votes; the Most Holy Virgin" had 4,132; sundry odd saints put in a poor show, polling in the aggregate 384 votes. After the election a Te Deum was sung and a sermon pronounced in celebration of the joyful event.

Building Intelligence.

CHURCHES AND CHAPELS.

The parish church of Croxall, near Tamworth, which has been closed for some months for alterations and improvements, was reopened on Tuesday week. The old square pews have been replaced by handsome oak benches, a new pulpit of Mansfield stone has been placed in the north-east corner, near the chancel arch. The organ has been removed from the west end of the church to a recess built for it on the north side of the chancel. The works have been done by Mr. Lilly, of Measham, from plans by Mr. Street.

A new United Methodist Free Church was opened at Keighley on the 16th ult. The style is Gothic, and the plan consists of a parallelogram, 86ft. by 48ft. within the walls, with an apsidal projection 20ft. deep at the rear for orchestra. The interior is divided into nave and aisles by iron columns, from which springs an arcade of seven arches on each side, which supports open hammer-beam trusses across the nave. There is a square tower at one corner, surmounted by an octagonal turret and spire, the total height being 125ft. The stained glass of the windows has been executed by Messrs. Edmundson and Son, of Manchester. Mr. William Sugden, of Leek, Staffordshire, was the architect, and the contractors for the several departments of labour were all local men. The total outlay is about £5,000.

On Thursday, October 15, a new iron church was opened at New Wandsworth, erected for Rev. J. S. Jenkinson, the vicar of Battersea, by Messrs. Francis Morton and Co. (Limited), engineers, Government contractors, and iron church builders, of London, Liverpool, and Glasgow, in a very satisfactory manner—the interior, with its side arches and clustered columns, its lofty open timber roof and handsome stained glass windows and plastered walls, being quite as elegant and comfortable as a brick or stone building. There is accommodation for about 500 persons, and the entire cost of the church, including gasfittings, heating brickwerk, drains, laying out and planting ground with trees, &c., was under £3 per sitting.

On Saturday afternoon the ceremony of laying the foundation stone of St. Paul's Church, High Town, Crewe, was performed by Mr. T. B. Horsfall, M.P. A suitable site has been secured, upon which will be erected a stone building in the Gothic style of architecture, from designs furnished by Mr. J. W. Stansby, engineer to the London and North-Western Railway Company. The estimated expense, including the price of the land, is between £6,000 and £7,000. The nave alone (the dimensions of which are 100ft. by 41ft.) is now being erected. As additional funds are received, the chancel, transept, and tower will be added. Accommodation will be provided in the nave for 700 worshippers, and, when the entire building is erected, for 1,000. The church is being erected by Messrs. P. and J. Parker, of Burnley.

St. Saviour's Church, Preston, was consecrated on the 29th ult. The plan consists of a nave and broad aisle, the latter containing a gallery. The completion of the exterior requires a tower on its upper stages. The architect is James Hibbert, Esq., of Preston.

St. Paul's Church, Blackburn, was reopened on the 1st inst., after restoration, which embraces the removal of the old pews across the gallery at the east end of the nave, the erection of new chancel, with large three-light windows, and two spacious entrances on either side, with wide stone staircases for access to the galleries. The roof, previously ceiled at the square, has been opened out to the collar beam, and the whole boarded, stained, and varnished, adding a great effect to the appearance and comfort of the interior. There are also 200 additional seats provided. The work has been executed from designs by Mr. James Bertwistle, architect, Blackburn.

A new Anglican Church is being built at Nazareth, in the Holy Land, at a cost of £2,000. The plans were originally designed by Mr. Schiek, of Jerusalem, and were subsequently revised by Mr. Stadlen, of Zurich. We willingly state that Mr. T. Brocklebank, of the Royal Bank Buildings, Dale-street, Liverpool, or his bankers, Messrs. Heywood and Son, would be glad to receive subscriptions towards its erection, as the extreme poverty of the natives greatly hinders the erection of this the only Anglican church in the district.

BUILDINGS.

On Wednesday, October 28, the foundation stone of a new Convalescent Home, at Meltham Mills, near Huddersfield, was laid by Earl De Grey and Ripon, with full Masonic honours. The building, which will cost £30,000, is the gift of Mr. Charles Brooke, jun., of the firm Brooke and Brothers, thread manufacturers, and is intended as an adjunct to the Huddersfield infirmary. The style of architecture of the hospital is of the Domestic Gothic character, with a few modern developments. The main front will face north east, and be about 190ft. long. The centre part of this will project a little, and will be devoted to the administrative department, and will contain on the ground floor a central entrance, with matron's parlour, surgeons' consulting rooms, and patients' waiting room. The wards branch out right and left for each sex, and consist, on the ground floor, of spacious staircases and corridors, which, being on the south side, will be agreeable for invalids in bad weather, leading to the convalescent day rooms and night wards for the infirm. The patients' entrances from the recreation grounds will be to the main staircases, under covered glass porticoes; extending further south-west is a dining hall, with the kitchens, pantries, and store rooms beyond. The buildings are to be constructed of Yorkshire stone, and will be erected from the plan and designs prepared by Mr. Edward Birchall, architect, of Leeds, and carried out under the superintendence of Messrs. Kirk and Sons, architects, Huddersfield.

On the 24th ult. the foundation stone of the new baths, the gift to the town of Staleybridge of Mr. and Mrs. Robert Platt, was laid by that gentleman in the presence of a very numerous assembly. The usual ceremony of presenting the trowel could not be adopted, as Messrs. Hunt and Roskell, who are preparing it, had been unable to complete it in time, and a rough model of it had to do the work as deputy for the very beautiful one in course of construction, and which will cost about £50. This has been subscribed for by some 5,000 inhabitants in sums varying from 1s. to 1d. each—a spontaneous expression of the people's appreciation of Mr. and Mrs. Platt's princely liberality. The building will front the church and market hall, and the centre of the entrance portico will be opposite the middle of Church-street. There will be an enclosed swimming bath 70ft. by 40ft., and an open one 80ft. by 40ft. for summer use. Private baths and Turkish baths are also provided, and all the latest luxuries in balneation will be adopted. The style of the building is Italian and of simple character.

Improvements are about to be made for the proprietors of the Albion Assembly Rooms, North Shields, by the addition of a new "first-class" staircase and retiring room, new second and third-class refreshment rooms, and an extension of the gallery accommodation, the last to admit of an increased admission of 500 adults. The refreshment rooms will be 37ft. by 22ft. and 12ft. high, while the ground-floor will be occupied as shops; the total height of the building approaching 50ft. The plans, which have been prepared by Mr. J. P. Spencer, architect, of Wantage and London, were passed by the Local Board of Health on Wednesday week, and the work will be commenced early in the ensuing spring.

One of the largest and most imposing buildings belonging to the Roman Catholics is about to be erected a short distance from Dublin, and is to comprise a college and a church. In addition to the usual offices there will be noble reception rooms, fifty-two private studies, and about seventy-five bedrooms. The principal or south front will have a magnificent façade, upwards of 300ft. long, from the centre of which will rise an equatorial observatory, forming a tower, with transept and observation rooms. At the eastern end of the college will be placed the church, access to the same being obtained from the college by an elaborately groined cloister upwards of 100ft. long. The church will consist of nave, chancel, transepts, baptistery, and a tower 260ft. high. A stream of water running near the college will be judiciously made use of by the architect for raising the two lifts which the college will be supplied with. The style of architecture employed is Decorated Gothic, and the whole of the designs are by T. W. James, Esq., architect, of Salterton, near Exeter, and Birmingham, whose plans have been selected in a limited competition.

Yesterday week the new Corn Exchange at York was inaugurated. The building is 74ft. long by 63ft. wide, and about 51ft. high. The cost is about £3,000. Mr. G. A. Dean, of London and York, is the architect, and Messrs. Weatherby and Rymer, of York, the contractors.

On Wednesday week the St. Edith's Home of Rest for the aged poor of the parish of Emscote, Warwick, was opened by the Lord Bishop of Dunedin. The architect was Mr. Robinson, of Leamington and Manchester, the builder was Mr. Smith, of Chilvers Coton, and the contract for the work was £800. The building is three stories high, its architecture Gothic, and it comprises a common room, a sitting room, kitchen, and bedrooms.

TO CORRESPONDENTS.

NOTICE.—Cases for binding the BUILDING NEWS, Vol. XIV., are now ready, price 2s. each.

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

RECEIVED.—T. E. D.—J. H.—R. S. and Co.—J. P. S.—C. E.—F. A. P.—G. T. R.—T. C.—E. T. Cox.—J. B. (Blackburne.)—E. and P.—W. M.—S. M.—G. S.

G. S. A. (Glasgow.)—The designs you refer to are spoken highly of by other subscribers, thus showing how hard it is to please all.

A WORKING MAN.—Suggestions from subscribers like yourself are always valued, and shall be borne in mind.

THOMAS WHITAKER.—We cannot understand your question. If you will put it more explicitly we shall have great pleasure in inserting it. Was the wall blown down during the erection of the roof? If so, do you wish to know whether yourself or the joiner is responsible? And, speaking of plans and specifications, what do you mean by "the original?" Do you mean the agreement or contract?

Correspondence.

CATHEDRAL ORGANS.

To the Editor of the BUILDING NEWS.

SIR,—The letters of "Ecclesiologist," "W.P.," "C. S. J.," and other writers are confirmatory of the view I have taken in common with the restorers or improversof St. Paul's, Westminster Abbey, and other of our cathedral churches in respect to the position of the organ. The dictum I affirmed in my letter, that the "organ in *itself* was subsidiary or subservient to sound," however much of a truism it may have appeared to "C. B. A.," has at least been acted upon, and therefore recognised by those well able to judge and who can connect a general law or broad principle with subsidiary duties. It would be absurd to impair the effect of the size and grandeur of one art by the mere means or mechanical vehicle of another (as an organ case), to say nothing of the relative superiority of architecture and instrumental music. The voice of antiquity as well as that of modern art concur in placing the organ somewhere at the side least obstructive in the general view, and it was only Puritanic zeal in a reactionary age that wholly discountenanced the usage and put the instrument on the choir screen to best effect the object of the day, viz., to convert the serviceable parts of our cathedrals into "panelled snuggeries." The division of the organ into two parts on both sides of the nave, instead of obstructing the latter, seems a good arrangement, and could be architecturally managed. Discarding a sentimental mediævalism on the one hand and an over scrupulous religiousness on the other, there is a proper subordination to be observed in art as in religious accompaniments.—I am, &c.,

G. H. G.

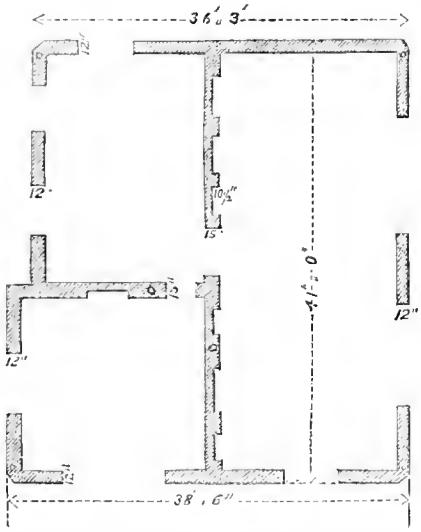
SIR,—I have been much interested in the correspondence relative to the position and effect of organs in cathedrals that has appeared in your columns. Without being a critic I may yet speak a word in favour of retaining, where possible, the effect referred to by "C. B. A." I have noticed it in York Minster, and admired it there. So far from lessening or interfering with the effect of the preceding music, it seemed the noblest finish to it, and "like the rush of angels' wings."

I trust I may be pardoned if I take objection to the way in which one or more of your correspondents have tried to throw discredit on certain effects by the use of depreciative epithets.

In music, as in other arts, there is wide scope, and nothing good in any should be thrown away. If softness and delicacy are best in their proper place, yet grandeur, sublimity, or pathos must sometimes have the sway. Is there no music in the sounding sea or in the sighing or occasional roar of the wind through the forest trees? If there is sometimes the simple note, shall there not also be the roar of the multitude, and the voice like "the sound of many waters"?—I am, &c., G. M.

CONCRETE BUILDINGS.

Sir,—With reference to G. Larden's letter in your last issue, I trust you will allow me to state the following facts, and contradict statements made by him. In the first place, the clerk of the works recommended by myself was one who had successfully carried out much larger works than that at Twickenham—viz., the concrete house at East Sheen of thirty rooms, with concrete floors and 12-inch walls; also one at Ealing with the same apparatus. The responsibility of construction does not rest with the clerk of the works, he being under the control of the architect. I enclose you a plan, showing at a glance the great



defects in carrying up the skeleton, 38ft. high, without floor joists or tie whatever (a very unusual course with any building), this being done on account of the delay in obtaining the iron joists from Belgium. You will notice circular openings for a 5-inch rain-water pipe, and the chamfering at each quoin, materially weakening a part where strength is so very essential; also the number of openings and recesses for fireplaces and cupboards in the party wall, formed to the proprietor's instructions, leaving a back of concrete only 4½in. thick, making the mainstay to the outer walls the weakest part of the building; also the number of wide openings in the front and back walls. Combining these defects with bad cement and bad foundations in the front, is the result to be wondered at? With respect to the work being under my superintendence or being in any way responsible, this I totally deny, as I do not in any case undertake the supervision of any building whatever. I also emphatically deny G. Larden's statement as to my being on the works when three stories in height, and hold him responsible for any step I may take to compel him to contradict this and other assertions. I visited the works once when 9ft. high, and then pointed out to the clerk of the works the serious defects at each quoin, and advised him to obtain the rain-water pipe and put in with neat Portland cement without loss of time to remedy this great defect, and which I fully expected had been attended to. The cement, some of the worst I ever saw, was purchased of a dealer instead of a manufacturer, because it could be obtained at 1d. per bushel cheaper. As to the ruins G. Larden speaks of, showing no blocks of concrete, but simply rubble as out of a gravel pit, this is not true. I and several practical gentlemen who visited the works during the pulling down of the house, noticed solid blocks of concrete from 3ft. to 5ft. long being broken in pieces by two labourers with their picks. I also wish to mention that I waited upon G. Larden with his architect, and proposed rebuilding the house in concrete, guaranteeing its safe erection under a penalty of £500, through his architect, on condition that the cement obtained be of a good maker, and the erection entirely under my supervision; but this he refused to do, and with respect to the arrangement made as to my taking back the apparatus at half its original cost, this I am quite willing to do as soon as G. Larden fulfils his agreement.—I am, &c., J. Tall.

Falstaff-yard, Kent-street, Southwark,
November 3.

Sir,—Seeing Dr. Larden's letter in your last week's issue as to the fall of a portion of his concrete house at Twickenham, I (now constructing a large warehouse 70ft. by 50ft. and 60ft. high, of the same material, with Mr. Tall's patent apparatus) visited Twickenham for the especial purpose of obtaining any information on the subject, and am happy to say that I had no cause whatever for anxiety, for it only required a passing glance to see at once the reason of the failure.

In the whole height of the building (about 40ft.) I could not trace a single tie or brace of any kind, *not even a joist*, and the only support to the main walls, the party wall, was recessed to such an extent as to be apparently useless for the purpose of a support, and the corners of the building I noticed not only cut off but deeply indented for a rain water pipe, materially reducing this important part for strength. The back and front walls, about 40ft. long, had numerous large openings from 9ft. to 10ft. wide in them for windows and doors. Combining these defects in construction with (as I was informed) a very inferior foundation there is no wonder at the wall suddenly collapsing. As regards one portion of the Doctor's letter, I must respectfully differ, that is, where he states "the ruin throughout showed no blocks of concrete, but simply were as rubble out of a gravel pit." I saw blocks from 4ft. to 5ft. long in a solid mass in the fallen part, but cannot vouch for the bulk of the structure which had to be pulled down. I should not have the least fear in carrying my warehouse up 100ft. high in concrete, and for satisfaction I have tested the lower part of my building by breaking out portions of the granite-like concrete, a specimen of which I send you. I had upwards of 200 tons of gravel and other material packed on the ground floor immediately the basement walls were completed, and I invite all interested parties to visit my warehouse and judge for themselves.

I have been very careful in the selection of my Portland cement, knowing that the success of the building rests principally with this material.—I am, &c., H. Goodwin.

Great Guildford-street, Southwark, Nov. 4.

SOUTH KENSINGTON SKETCHING CLUB.

Sir,—A letter appeared in your last week's issue under the above heading. It would have been better to treat it with the silent contempt it deserves but that others of the same stamp relating to matters at South Kensington, and evidently by the same writer, have already passed unnoticed. The attack made by "Justice" has met with universal condemnation among the students of the art schools, and the mildest expression of opinion has been that the writer "ought to be ashamed of himself." The students generally have been disposed to take no *public* notice of the letter, but I for one feel it my duty to make some reply, and, as I was a competitor and am thoroughly cognisant of the whole facts, I can speak with something like certainty. The competition was strictly private, being got up among the students in training and others in July last, and a meeting was held to arrange the terms, which were to be similar to those of last year—viz., all works (foreground and landscape) done in the vacation being eligible. There was a small subscription and the prizes were a sort of sweepstakes. To have the competition as fair as possible, there were two sections—A and B—the former for all comers, the latter set apart for general students only. Of this "Justice" has taken no notice. The head master and painting master, both of whom are artists, kindly consented to adjudicate, and the use of the life room was obtained. The so-called exhibition took place on Thursday, October 22, when the awards were made known. The drawings, &c., remained up until four o'clock, when, as the model was to sit in the evening, the students themselves took the works away. Everyone of the competitors saw the drawings with the exception of two of the evening students, and "Justice" was the only one dissatisfied with the fairness of the award. In section A, that more especially under notice, the first prize (water colour) was awarded to a foreground study, 12in. by 10in., not 6in. by 4in., as stated by "Justice." It *was* a cemetery monument, but with grass and well-drawn foliage, too—the cleverest thing in the display, and acknowledged as such by all but "Justice." The second prize was awarded to a carefully painted bit of country, 15in. by 12in., the work of a student in training much respected in the schools, who acts in such matters as our treasurer. The first prize in oils was carried off by a very excellent painting of the Thames beyond Putney, and not, as suggested, "a bunch of grapes and dead robin." The second prize again fell to our treasurer, and the allusion of "Justice" to trees, &c., ¼in. diameter, possessing neither power nor feeling, is simply nonsense. Each of the statements of "Justice" is either twisted to suit his purpose or palpably false. The wonder has been why such a letter suggested itself, and the reason is obvious that "Justice" had plumed himself upon success, and had moreover attached his name to each of his drawings, quite contrary to the rules; and, further, he had counted upon a *public recognition* of his talents.

The only grumbler has been "Justice" himself, though his letter would seem to show that he spoke in the interest of many. It has been too transparent a case of "Dog in the manger," and has only succeeded in bringing ridicule upon itself. The several spiteful insinuations against the training in an institution to which "Justice" owes his little fame are beneath notice, but I must say that the statement as to the masters "sneaking away" is a downright falsehood. Apologising for occupying so much of your valuable space, I am, &c., T. M. L.

Intercommunication.

QUESTIONS.

[1109.]—LAND SURVEYORS' CHARGES.—Will any of your readers kindly inform me, through your columns for "Intercommunication" how and at what rate a land surveyor is paid in the following instance?—Required to survey a tract of land about 100 acres in extent for the purpose of building. A map to be drawn out of the same divided into roads and plots. The management afterwards is to be left in the surveyor's hands, and all applications to be made to him.—X.

[1110.]—ANCIENT LIGHTS.—Can any of your readers inform me if I can stop up a window that has at some time been put in a wall which has been raised upon the end wall of my house and belonging to me, my house being two stories and my neighbour's three. He has built the end wall of his house upon my wall, and also put in a window overlooking my property. I now wish to raise my house, and cannot do so unless I can stop up the said window.—H. C.

[1111.]—STAIRCASE LIGHT.—Will you or any of your correspondents kindly furnish a subscriber with information as to how near an owner of adjoining property can build against a staircase window which has been uninterrupted upwards of 200 years.—G. C.

[1112.]—STRENGTH OF WALLS.—Will you allow me to ask your experienced readers if one of them will inform me how I am to calculate the thickness the walls of a building require to be to resist the outward thrust of the roof where there are no tie beams?—Inexperience.

[1113.]—VENTILATION STOVE AND LAMP.—Can any of your readers inform me if the ventilation stove and lamp of Mr. J. D. Morrison, Edinburgh, described in the Building News of August 21, p. 566, is patented, or if not patented where I can obtain descriptive drawings of the apparatus?—Ventilation.

[1114.]—MACHINE WORK.—Is it possible to obtain mouldings correctly worked out of *seasoned* material and of the quality ordered? My experience is that all mouldings obtained in my own locality are worked out of green stuff of the most inferior description, and so far from being true it is impossible to make a good fit at a mitre; if I wish to do my work in a respectable manner the only chance is by having recourse to hand labour instead of machinery. I shall be glad if any of your readers can inform me where a good honest article can be obtained.—One of the Olden Times.

[1115.]—GELATINE.—Will any of your readers be kind enough to inform me where I can procure the gelatine such as is used by modellers, and the price of it?—E.K.T.

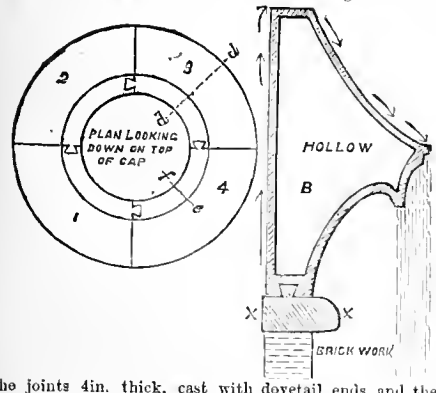
[1116.]—WATERPROOF WOODSHED.—Can any of your correspondents inform me as to the best method of making a woodshed waterproof?—R. H.

[1117.]—DISCOLORATION OF STONE.—I have a quantity of wallstone which has become much discoloured by lying in a field during the last twelve months. I should feel much obliged to any of your readers who could inform me how to remove (or partially so) this discoloration.—SUBSCRIBER.

REPLIES.

[1051.]—STRAIN ON WROUGHT-IRON TRUSS.—I cannot put my question more distinctly than I have done. I want to know if "Constant Subscriber" can assist me. When I was working out the strains I came to this formula as in this week's BUILDING NEWS, and, as stated in the issue of October 16, I could not understand the formula, and I should feel truly grateful if "Constant Subscriber" will explain it.—R.

[1059.]—FACTORY CHIMNEY FLUES AND SHAFTS.—Having read your correspondent's remarks on chimney caps, and of the very narrow chance of being turned topsy-turvy—indeed it was a miracle—I do not consider stone or brick capping at all suitable for such work, and more especially if they must be clamped, or as it were bound together like an old woman's waist. The accompanying sketch will show to "L. M." and all others doing similar work that cast-iron caps such as I have sketched would be far more preferable, and probably cheaper to use, than either of the former, B section being quite hollow in the centre, d d, the outer and inner rim being inch thick,



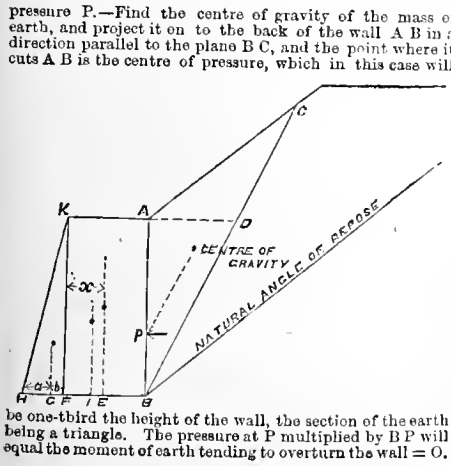
the joints 4in. thick, cast with dovetail ends, and the whole depth of cap caulked with lead. From f to e should be 14in. wide. The bed mould should be of iron, similarly dovetailed together, with dowels on the upper bed tailed into capping, see section X X. By moulding the caps in cast iron or other metal, a much larger projection could be given, the quirking and under grooving could have more acute angles, thus preventing soot and rain trickling down the face of the shaft. I have laid out my capping in four pieces, but there might be eight joints if requisite, for once set they would form one block. The iron work should be either galvanised or painted four coats in red lead.—FRANCIS HANSOM LUSCOMBE.

[1071.]—BAKERS' OVENS.—I should feel obliged if any of your numerous readers would kindly inform me the best way of constructing and heating bakers' ovens?—AMATEUR.

[1076.]—PRESSURE UPON SAFETY VALVES.—Should not "Engineer's" answer to this, in your last impression, be 20lb. instead of 30lb., as therein stated? He has also omitted to state that the assumed area of the valve in his reply should be one square inch. Thus we have—

$$P = \frac{10 \times 6}{3 \times 1} = 20\text{lb.}$$—AMATEUR.

[1080.]—RETAINING WALLS.—As "X + Y" does not appear to have received a satisfactory solution of his question as to the pressure of a surcharged embankment against a retaining wall, and a method of finding the thickness of such wall when battering either on the face or towards the bank, I have given the matter a little consideration, and beg to submit to him the result of my investigation. My diagram will be sufficiently clear to him without description. First, then, as to the pressure of earth against the wall. The portion tending to slip and to be retained is the triangle A B C. Its pressure against the wall will be its weight × tang. of angle A B C on $\frac{\text{W A D}}{\text{A B}}$. To find the centre of pressure P.—Find the centre of gravity of the mass of earth, and project it on to the back of the wall A B in a direction parallel to the plane B C, and the point where it cuts A B is the centre of pressure, which in this case will



be one-third the height of the wall, the section of the earth being a triangle. The pressure at P multiplied by B P will equal the moment of earth tending to overturn the wall = O.

To find the width K A of the wall, the height and inclination of batter being given—let w = weight of face of wall K H F, or $\frac{\text{K F} \times \text{H F}}{2} \times$ weight per cubic foot; a = distance H G, or two-thirds H F; b = distance G F, or one third H F; x = half additional thickness of wall K A; W = height of wall × weight per cubic foot. The centres of gravity of the two portions of the wall pass vertically through G and E, and that of the whole wall through I. The distance G I is proportional to I E, as the weight of K A F B is to K H F. Thus as $w + 2\,W\,x : b + x :: 2\,W\,x \times (b + x)$ $W\,x : G\,I$; or, $\frac{2\,W\,x \times (b + x)}{W + 2\,W\,x} = G\,I$. The entire weight of wall is $W + 2\,W\,x$, and its moment $\frac{2\,W\,x \times (b + x)}{W + 2\,W\,x} + a$, which multiplied together, gives $(2\,W)\,x^2 + (2\,W\,a + 2\,w\,b)\,x \times w\,a = O$, which reduced will give the formula

$$x = \sqrt{\frac{o - w\,a}{2\,W} + \left(\frac{a + b}{2}\right)^2} - \frac{a + b}{2}$$

The thickness of the wall K A = 2 x. The formula for wall with a batter towards the bank will be

$$x = \sqrt{\frac{o - w\,b}{2\,W} + \left(\frac{w}{2\,W}\right)^2} - \frac{w}{2\,W}$$

x in this case is also half K A. These formulæ give the earth and wall in exact equilibrium.—J. L.

[1082.]—LIQUID GLUE.—Recipe No. 1.—Orange shellac and rectified naphtha put together in a bottle will dissolve in less than 24 hours. It must be kept corked, or a film will be formed over the surface. Recipe No. 2.—Boil some glue in the ordinary manner in water, and while boiling drop in slowly nitric acid. The exact proportion of nitric acid I forget, but it may easily be found by experiment.—N. N. N.

[1083.]—WATER SUPPLY.—In answer to "Waterworks" I beg to inform him to fix one or two rain gauges in favourable situations, and the quantity of rainfall thus registered, multiplied by the surface area of gathering ground, will give him the amount of water available for storage. Allowance for overflow of storm water, percolation and evaporation to be deducted, particulars of which he can find in "Beadmire's Hydrology." Existing springs should be daily gauged, for, although the rain gauge may register a certain quantity, the springs may widely differ according to the geological strata. All springs in elevated regions are fed from the clouds, the regularity of flow depending upon the subterranean reservoirs. I am connected with waterworks, and would willingly render "Waterworks" further information through your "Intercommunication" or otherwise.—WM. WATTS.

[1094.]—BARK OF TIMBER.—In reply to "Bailiff," I beg to say that in twenty years' experience of the purchase and sale of round timber, the only rule I have ever known is 1in. to the foot on the girth. But the usual method of measuring round timber, although convenient, is so very far from correct that it is quite possible different customs may prevail in different localities. I once heard of a bailiff who wished to allow less than 1in. to the foot on young timber; but do not consider that he had any right to deviate from the rule above given.—HENRY CONWAY, builder, &c., Evershot, Dorset.

[1095.]—GRADIENTS.—The following table and formula, taken from "Molesworth," page 40, will, I think, supply "A Young Leveller" with the information he seeks:—

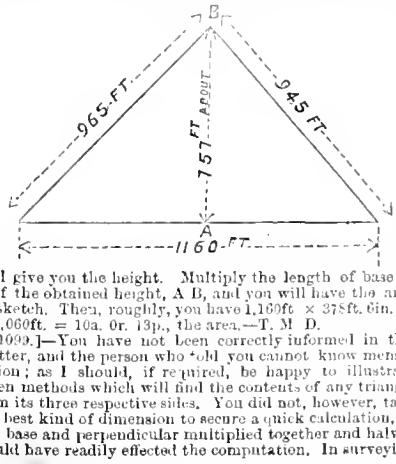
Rise per mile and resistance due to gravity alone.

Gradient of 1 in	20	25	30	35	40	45	50	60	70	80	90	100
Rise in ft. per mile	264	211	176	151	132	117	105	88	75	66	58	52
Resistance in lbs. per ton of train	112	83½	74½	64	56	50	45	38	32	28	25	22

Resistance due to gravity on any incline in lbs. per ton of train $= \frac{2240}{\text{rate of gradient}}$. Therefore, a rise of 30ft. in 3600ft. gives a gradient of 1 in 120, and $\frac{2240}{120} = 18.66$lb. per ton of train.—GEO. W. USILL.

[1097.]—WATERING OF RIVERS.—"W. W." has forgotten to give a vastly important item in his requisition, the *rate of inclination*, without which it will be impossible to ascertain the quantity of water discharged per minute.—GEO. W. USILL.

[1099.]—AREA OF TRIANGLES.—All you have to do is to draw the triangle out on paper to any scale; take one of the sides as the base (say the 1,160ft. one); draw the line A B (at right angles to base) from base to apex, which



will give you the height. Multiply the length of base by half the obtained height, A B, and you will have the area as sketch. Then, roughly, you have 1,160ft × 378ft. 6in. = 439,060ft. = 10a. 0r. 13p., the area.—T. M. D.

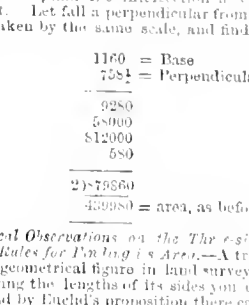
[1099.]—You have not been correctly informed in this matter, and the person who told you cannot know mensuration; as I should, if required, be happy to illustrate seven methods which will find the contents of any triangle from its three respective sides. You did not, however, take the best kind of dimension to secure a quick calculation, as the base and perpendicular multiplied together and halved would have readily effected the computation. In surveying it is customary to measure the three sides, and a line from a point in one side to another side or angular point, which line, on scaling the figure, proves the exactness of position of its angular points. The perpendicular is then deduced from the same scale to which the figure was plotted. Such a method I should recommend you to try in the present case. The first method to find the contents of the triangle in question which I shall describe is an old-fashioned method, but it is simplified much by Logarithm tables, the absence of which renders me unable to shorten the work. *Method the First* (by the old rule).—Firstly. Add together the sides, and halve the sum, from which deduct each side severally, thus:

1160	1535	1535	1535
945	1160	945	965
965			
2)3070	375	590	570
1,535ft.			

Secondly—Multiply the half sum and the differences continually together, and the product will be the square of the superficies. 1,535 × 375 × 590 × 570 = 187,382,637,500 = the square of the area in feet. Thirdly—Take the square root of these figures for the area,

$$\sqrt{187,382,637,500} = 433,080.3$$

= area in square feet, or 44,000 square feet, sufficiently true for practice. *Method the Second* (by the plotting scale).—From a scale of equal parts set out the base A B 1160. From the same scale take 965, and with the feet of



the compass in B describe the arc a a. From the same scale take 945, and with the feet of the compass in A describe the arc b b, and the intersection at C is the third angular point. Let fall a perpendicular from C on to A B = 758·5, as taken by the same scale, and find the area as follows:—

1160	= Base
758½	= Perpendicular.
9280	
58000	
812000	
680	
2)878860	
439080	= area, as before.

Trigonometrical Observations on the Three-sided Figure, and Further Rules for Finding its Area.—A triangle is the only correct geometrical figure in land surveying, because without altering the lengths of its sides you cannot alter its shape; and by Euclid's proposition there cannot be two triangles having two sides of the one terminated in one extremity of the base, and likewise those terminated in the other extremity, equal to each other. Trigonometry teaches the art of measuring triangles, and shows the relationship between their sides and angles; for it is evident that the angles must be proportionate to the sides when the greater angle is always subtended by the greater side, and the lesser angle by the lesser side. Again, the three interior angles of every triangle are together equal to two right angles, or 180 deg.; hence, the measurement of an angle is the number of degrees, &c., it contains, or so many equal parts of the circumference of any circle divided into 360 equal parts. There are various instruments used for taking angles, such as the plain table, circumferentor, prismatic compass, box sextant, and theodolite; the latter of which is recommended for accuracy, as it takes the horizontal and vertical angle at the same time. The following algebraic rule will be found useful in finding the area of a triangle from two sides and an included angle:—

Let A B and B C = two sides, and ∠ A B C = included angle.
∴ Log. A B + Log. B C + Log. sine ∠ A B C = x.
x — 15.301 = Log. of area.

Also, when one side and two adjacent angles are given:—
Let A B = base, and ∠ A B C and ∠ C A B the adjacent angles.
Then Log. A B + Log. sine ∠ A B C + Log. sine ∠ C A B = x.
Then Log. sine (∠ A B C + C A B) + 10.301 = y.
x — y = Log. of area.—ROBERT CARPENTER, accountant and surveyor.

[1099.]—"V. P." has been wrongly informed. It is not necessary to measure one of the angles of a triangle to ascertain the area. Rule: Add the three sides together, then take half the sum of the three sides, subtract each side severally from this quantity, then multiply this and the three remainders together, and take the square root for the area. Example: What is the area of a triangle whose three sides are 30, 40, and 50 chains?

$$\frac{30 + 40 + 50}{2} = 60 = \text{half sum.}$$

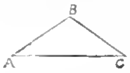
60	60	60
30	40	50
30 ×	20 ×	10 × 60 = 360000 chains.

Answer: $= \sqrt{360000} = 600$ chains = 60 acres.
"V. P." I think must have made an error in giving the length of one side of his triangle.—W. R. ATKINSON.

[1099.] "V. P." will find the rule for calculating the area of a triangle having three sides, given in BUILDING NEWS of September 11, which I will repeat:—"From half the sum of the three sides subtract each side severally, multiply the half sum and the three remainders continually together, and the square root of the last product will be the area."

1160 + 965 + 945	=	3070
3070 ÷ 2	=	1535
1535 — 1160	=	375
1535 — 965	=	570
1535 — 945	=	590
1535 × 375 × 570 × 590	=	193582637500
$\sqrt{193582637500}$	=	439080.3, area of triangle in feet.—R.

[1099.]—I see your correspondent "V. P." wishes to find the area of an unequal-sided triangle of certain dimensions. He might have found the rule by consulting any good mensuration. It is this: From half the sum of the three sides added together deduct each side separately; then multiply the half sum and the three remainders continually together; extract the square root, and the result will be the area. Example:



Let A B = 945ft. ,, B C = 965 ,, A C = 1160 — 2)3070 — 1535

	1535	1535	1535
	945	965	1160
Then	590	570	375

and 1535 × 590 × 570 × 375 = $\sqrt{2}$ 193582687500 = 439980.3ft. super. Answer—10 acres, 0 roods, 16.06 rods, poles, or perches.

I hope this will give him the information he wants.—GRAY.

[1106.]—SETTING OUT A CURVE.—The most accurate method for "Mason" to proceed to trace out a curve when there is not sufficient space to find the centre, would be as follows:—Let A B, Fig. 1, be the given length of curve, D C the height; make E F, Fig. 2, equal to the heights D C in Fig. 1. Describe the curves E G H. Then divide F H into as many number of parts as A D and

FIG. 1.

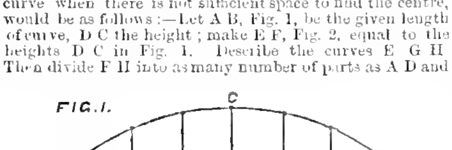

FIG. 2.

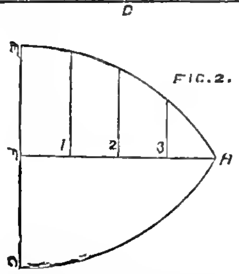
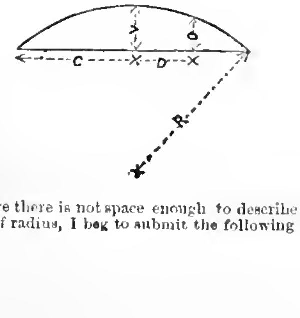


D B in Fig. 1. Square the ordinates, then take the various heights 1 2 3, Fig. 2, and set them at 1 2 3, Fig 1. Having obtained the heights, place nails in the several points, bend a slip of wood round these nails, care being taken to get it of equal thickness; then, by drawing a pencil along this slip, the required curve line will be obtained.—H HOWELL, Neath

[1106.]—In reply to "Mason," relative to setting out a

FIG. 1.



curve where there is not space enough to describe it from the point of radius, I beg to submit the following formula and calculation, which may be useful to him:—

$$O = \sqrt{R^2 - D^2} - (R - V)$$

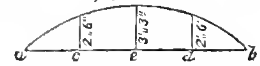
Where R = radius.
C = semichord.
V = versed sine.
D = distance of ordinate from centre.
O = any ordinate.

Example:
Let R = 25ft. 8in. = 25.66
D = 6ft. 3in. = 6.25 (say half semichord
V = 3ft. 3in. = 3.25 for example.)

Then $\sqrt{25.66^2 - 6.25^2} - (25.66 - 3.25.)$
$= \sqrt{658.4356 - 39.0625} - (25.66 - 3.25)$
$= \sqrt{619.3731} - (25.66 - 3.25)$
$= 24.88 - (25.66 - 3.25)$ [nearly.]
$= 24.88 - 22.41 = 2.47 =$ 2ft. 6in.

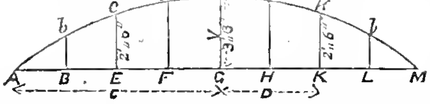
Therefore length of O is 2ft. 6in., and if "Mason" divides his chord or span into four equal parts he will find his rise a V at e (fig. 2) is 3ft. 3in., and the height of ordinate at c

FIG. 2.



and d to be 2ft. 6in., and if he wishes to prove the correctness of these heights if he will set out a line or chord 25ft. long and divide it into four equal parts (as in fig. 2) and set up 3ft. 3in. at e, and 2ft. 6in. at c and d, then from the point of radius describe an arc of 25ft. 8in. radius, he will find his curve will trace through the points measured from his chord. This should be done to a large scale. Of course if "Mason" wishes to have more points whereby to trace his curve he will have to increase the number of his ordinates, and in order to do this he must be careful that he accurately ascertain the length of D and use the same formula with the exception of the difference in length of D. For instance, let him divide his chord into eight equal parts (see fig. 3), and proceed in the same manner to ascertain

FIG. 3.



the heights of H h, F f, and L l, B b, as I have for those of K k, E e, and by this means he may trace his curve without the aid of a radius. There are other ways of setting out curves, but would hardly apply to so small a radius, and I think this formula is the most simple.—GEO. W. USILL.

[We have also received similar answers from "A Carpenter," "G. H., Swansea," and "A Joiner, Melton Mowbray."—ED. B. N.]

[1107.]—TOOLS FOR WOOD CARVING.—In reply to your correspondent "L S," the best tools for carving in wood are made by Addis, of London, at 9d each and upwards (without handles) and can be purchased from any respectable ironmonger in the provinces.—W. B. HALL.

BUILDING AND LAND SOCIETIES.

AT the sixth annual meeting of the members of the Fourth City Mutual Building and Investment Society, held on Tuesday, at the City Terminus Hotel, Cannon-street, a report was presented stating that the money advanced during the year amounted to £16,060, and the total amount of advances since the commencement of the society was £149,925. The balance remaining to the credit of the profit and loss account, after carrying forward £40,040 8s. 10d. for future interest on advances, and adding £100 more to the reserve fund account, was £4,373 7s 6d., out of which interest would be paid on the original investing shares (that is, shares taken prior to the new issue, which commenced on March 13 last) at the rate of 8 per cent. per annum. The number of investing shares now in existence is 1,840, which (when fully paid up) will give a capital of £110,400, and of which £69,878 12s. 1d. remained to the credit of the members on September 30; and the amount received on investing shares will necessarily decrease yearly as the shares become completed or paid up, thereby decreasing the number on which subscriptions have to be received.

WAGES MOVEMENT.

THE master builders of Leeds have given notice of their intention to adopt, on May 1 next, very extensive and important alterations in the rules of the various trades. Instead of 30s. per week they propose to pay ordinary skilled workmen amongst masons 7½d per hour; plasterers, instead of 30s. per week, 6½d. per hour; plasterers' labourers, instead of 22s per week, 4½d. per hour; and plumbers, instead of 26s. per week, 5½d. per hour: superior or inferior workmen each trade to be paid by special agreement. They also require the abolition of the rule or custom in the masons' society forbidding or interfering with the introduction or use of stone work at the quarry, or anywhere else than the place where it is to be used. Any rule or custom forbidding piecework or subletting amongst masons and plasterers they also require to be abolished. With respect to the bricklayers, bricklayers' labourers, masons, masons' labourers, plasterers, plasterers' labourers, and the plumbers, the masters require that in future all trade rules, disputes, demands, and differences shall be settled by conciliation and arbitration, and that proper courts shall be constituted for that purpose. They further state that they are prepared at any time, upon six days' notice from the men, to meet them to appoint arbitrators and select an umpire, and that they are willing to leave to the decision of the arbitration court, thus appointed, not only all future settlement of trade rules, demands, and differences, but also the settlement of all matters contained in the notice they have just given.

STATUES, MEMORIALS, ETC.

A BEAUTIFUL memorial brass, in the mediæval style, sunk in a black slab of Irish marble, has just been executed by Messrs. Hart and Son, of Brook-street, Hanover-square, in whose show-rooms it has been greatly admired as a fine specimen of modern art workmanship. This tablet is to the memory of the late and sixth Earl of Harrington, and is now being erected in Elvaston Church, near Derby. The slab, considering its size, being 8ft. 6in. by nearly 4ft., is remarkable for its purity. The inlaid brass is both rich and delicately worked, the exquisitely enamelled portions being very effective, the colours harmonising well with the general design. The whole is bordered by appropriate texts and symbols. Under the canopy is a full-length portrait of his lordship in collegiate attire, and below this are illuminated the arms of the family, and the words:—"In the vault under this church, by the side of his father and elder brother, lie the mortal remains of Seymour Sydney Hyde, sixth Earl of Harrington, born 27th September, 1845; died, before attaining his majority, on the 22nd February, 1866."

STAINED GLASS.

THE church of St. Mary the Virgin, Collaton, near Paignton, Devon, has recently been enriched by the addition of an east window, in memory of the founder. In the three principal lights are represented—1. Our Blessed Lord bearing the cross; 2. The Crucifixion, our Lord commending His mother to the care of St. John; and 3. St. John leading away the Virgin Mother. In the central compartment is introduced the figure of St. Mary Magdalene, and in the first compartment those of the other two Marys. The two quatrefoils above are filled with representations of angels, and the highest quatrefoil with the emblem of the Lamb of God. A small separate light near the roof contains the emblem of the Virgin. One special feature is the introduction of trees and flowers. In the first compartment the palm-tree appears, and in the last the sycamore. The window was designed and executed by Messrs. Ward and Hughes, of London.

A window has lately been erected in the church of the Holy Cross, Tramore, near Waterford—the Brighton of Ireland. It consists of three lights and tracery of the Decorated style, and in the treatment great care has been taken in keeping the proper character of the period. The subjects are figures, life size, of the Blessed Virgin, and of the archangels St. Michael and St. Gabriel. The framework is of foliage admirably designed. The window is from the studio of Earley and Powells, Camden street works, Dublin, who have executed many similar works in Ireland.

LEGAL INTELLIGENCE.

BREACH OF THE BUILDING ACT.—Mr. Thomas Rae, builder, appeared before the Liverpool magistrates on Wednesday, October 28, to answer a summons taken out under the 71st section of the Building Act, in which he was charged with having made an opening more than six feet wide in the party wall between two buildings in Mill-street.—Mr. Atkinson appeared in support of the case, and called one of the building surveyors, who stated that the opening in question was 8ft. 2in. wide.—The defendant, as an answer to the case, stated that he had strengthened the wall by an iron beam, and had placed an iron pillar to support it in the centre of the opening, so that there was only 4ft. on each side. Mr. Atkinson said the act was very stringent, and the building surveyor was bound to report cases like this. Mr. Anderton (clerk to the justices) said the act under which the information was laid was framed before iron came into general use for building purposes. The building surveyor said the pillar and beam used by the defendant were perfectly sufficient for the purpose, and the wall was as strong as ever. Mr. Stitt said the bench felt inclined to dismiss the case, if they had the power to do so. The law-clerk, however, had informed them that a technical offence had been committed against the act, and, therefore, they must impose a nominal penalty. The magistrates inflicted a nominal penalty of 6d.

Messrs. Okell and Morrison, builders, Wavertree-road, were summoned for a similar offence. According to the evidence, it appeared that the opening in this case was 13ft. in width, but the wall was sufficiently strengthened by an iron beam. The building surveyor said he had no objection to this wall. Mr. Stitt observed that the bench regretted the defendants had been brought to the court on such a charge. At the same time, the building surveyor was doing his duty in laying the informations, thereby carrying out the provisions of the act. He (Mr. Stitt) thought the law upon the matter ought to be remedied. The gentleman who appeared for the defendants concurred in the remarks made by his worship, and expressed his conviction that the enforcement of such an act would stop all improvements within the borough. A nominal fine of 6d. was imposed, and a similar penalty was inflicted upon Mr. Andrew Sinclair, builder, summoned on a similar information.

THE DUKE OF BUCCLEUCH v. THE METROPOLITAN BOARD OF WORKS.—This was an action brought in the Court of Exchequer on Tuesday to enforce an award made by Mr. Charles Pollock, Q.C., giving compensation to the Duke of Buccleuch for injury done to Montagu House, Whitehall, by the works of the Thames Embankment. Mr. Hawkins, Q C, on the part of the defendants, now applied to be allowed to abandon the writ of error by which they had proceeded after the decision of their Lordships against them, and to carry the case to the Court of Error by way of an appeal from the judgment of the Court of Exchequer. He stated that the Duke of Buccleuch had consented to this course being adopted, and it only enabled the defendants to revert to the right which they originally had under the Common Law Procedure Act, without the consent of the court. Baron Channell: We cannot give you leave to appeal, because we positively refused to do so; but you can avail yourself of your right to appeal. The Lord Chief Baron: There can be no objection to your reverting to the right you possess under the Act of Parliament. Application granted.

The Emperor of the French is about to erect a number of houses for workpeople at Bayonne. Each dwelling is expected to cost 4,500f. The tenant is to pay 300f. a year, of which 100f. will be set aside as a sinking fund. The inhabitant will become the owner in fifteen years.

Our Office Table.

The first monthly meeting of the winter session of the London Association of Foremen Engineers is appointed to take place at the rooms of the Association, George Hotel, Aldermanbury, City, to-morrow, the 7th inst., at eight o'clock in the evening. On this occasion the secretary will produce a comprehensive statistical and financial statement illustrative of the progress and prospects of the institution.

The gallery which recently held the National Portrait Exhibition at the South Kensington Museum is now in course of being enriched with the famous collection illustrating the history of ancient armour as it existed in Europe from the Norman Conquest to the reign of King Charles II., formed by the late Sir Samuel Rush Meyrick, at Goodrich Court, Herefordshire, and which, together with the production in 1824 of his magnificent work on ancient armour, procured him a high place among the most eminent antiquaries of his time.

The death of Mr. William Thomas, clerk of the works to the Queen, occurred on Tuesday, somewhat suddenly, at his residence, Brunswick-terrace, Windsor. Although he had been unwell for some months past, his illness became alarming only on Monday, after he had been out riding, and he died on the following morning from the rupture of a bloodvessel in the head. Mr. Thomas was held in much respect by Her Majesty, by whom he had been entrusted to superintend the works of the Prince Consort's mausoleum, at Frogmore.

Photography is being made use of, and advantageously, as a means for testing the authenticity of supposed valuable pictures. It appears that some persons have "touched up" and "doctored" several unfinished pictures by the late Mr. John Phillip, R.A. His executors, therefore, have given notice that they had all his pictures, finished and unfinished, photographed before they were sold, so that any touched by other hands can at once be detected.

Mr. T. C. Sorby, on account of the increase of other duties, has resigned his appointment as Surveyor to the Metropolitan Police and Police Courts, and Mr. Caiger, the Deputy Surveyor, has been appointed by the Secretary of State to the vacancy. The principal buildings erected, and erecting from the designs of Mr. Sorby, are the Lambeth Police Court, police station at King's Cross-road, Vine-street, Wapping (High-street), Blackman-street, Hammersmith, Rochester-row, Sea-bridge, Bedfont, Richmond, and Ealing.

The progress in the construction of the Mont Cenis tunnel continues satisfactory. Nearly three-fourths of the tunnel are now completed, and the remainder is being constructed at a rate which will admit of the entire completion of the tunnel in about two years, should no unseen occurrence intervene. The total length of the tunnel will be 13,364 yards, and of this distance there had been driven to the end of September from the Bardonnèche end 5,700 yards, and from the Modane end 3,970 yards, making a total length completed of 9,670 yards, leaving 3,694 yards to drive. The operations at present are proceeding more rapidly on the French than on the Italian side.

The Arundel Society is about to issue a new work, being a description of its own publications during twenty years. This book will be illustrated, and has resulted from the success of some experiments in photographing the prints, casts, &c., on a small scale, suitable for book illustration, which the Society has issued during the period in question. The whole of the Society's works, including the ivory carving, will be reproduced in the chronological order of their former publication, and one-fifth the size of the originals. The Society will soon receive drawings, made by its artists in Italy and Germany, from the following famous pictures:— 1. "The Last Supper," from the fresco, by Andrea Del Sarto, in S. Salvi, near Florence; 2 and 3, "The Resurrection" and "Christ in the Garden," from frescoes by Fra Angelico, in S. Marco, Florence; 4, "The Virgin and Child," after a lately-discovered fresco by Fra Bartolomeo; 5, "Christ and his Disciples at Emmaus," after Fra Bartolomeo; 6, "The Adoration of the Shepherds," after Perugino, at Perugia; 7, "The Madonna," after Holbein, in the palace of Hesse-Darmstadt; 8 and 9, two paintings by A. Durer, "The Four Apostles," at Munich; 10, 11, and 12, three interesting drawings after Piero della Francesca.

Patents for Inventions

CONNECTED WITH THE BUILDING TRADE.

420 G. TUCKER. IMPROVEMENTS IN THE MANUFACTURE OF RAIN-WATER PIPES, &c. Dated February 7, 1868.

This invention consists of certain improvements in the manufacture of such cast iron goods as sash weights, rain-water pipes and gutters and their connections, furnace pans, and hot water pipes, and their connections. These improvements consist in casting the requisite articles in chills made of the required shape, whereby great economy in the manufacture of large quantities is obtained with a harder and more durable surface. The molten metal is poured into the chill, which is a cold metallic mould of the shape required, and the sudden cooling thus occasioned converts the surface into an extremely hard white iron.—Patent abandoned.

421 G. HARFORD. IMPROVEMENTS IN SCAFFOLDING, AND APPARATUS TO BE USED FOR BUILDING AND OTHER SIMILAR PURPOSES. Dated February 8, 1868.

The inventor forms all around the object to be constructed, whether it be a chimney, a wall, a vessel, or other erection, a double frame consisting of sole plates or pieces at right angles to or parallel with and passing through the thickness of the wall, into which sole plates or pieces, both on the outside and inside of the wall, uprights are fastened either by mortises or screws, or in any other convenient manner; these uprights may be of any convenient length, but he proposes that, when the invention is used in the building of a house, they should be equal in length to the height of one story of the house; the tops of these uprights are to be kept in their proper places by cross-bars or beams. On the crossbars or beams is placed a rack and pinion or screws, so that, when the building is completed to the height of the uprights, the entire framing may be raised from off the sole plates or pieces to the height of the next story or portion, after which the sole plates or pieces used at the lower portion of the building may be withdrawn, and placed upon and across the completed portion of the building, and the framing rested upon them, and so on until the entire building or construction is complete.—Patent abandoned.

426 T. WALKER. IMPROVEMENTS IN THE CONSTRUCTION OF SEWERS AND DRAIN PIPES OR TUBES. Dated February 8, 1868.

As sewers and drain pipes or tubes are at present arranged, the subsidiary or feeding channels open into them at their upper parts or above the ordinary level of the sewage water therein, by which the effluvia from the matters in such sewers or main drain pipes or tubes rises up the subsidiary or feeding channels into the streets or ways, and, in some cases, into the surrounding dwellings, with most injurious results. The object of these improvements is to remedy these evils, and, for this purpose, the patentee arranges the openings for the subsidiary or feeding channels into the mains at the bottom thereof, or where the outlets or mouths of the subsidiary drains into the mains will be covered by any sewage water in such mains, and the subsidiary or feeding drains will thereby become self sealing or self trapping. The patentee forms pipe drains with these branches on their lower sides inclining upwards at an angle or passing partly round the external surface of the pipe or tube to the gallery or other inlet.—Patent completed.

441 N. C. SZERELMEY. IMPROVEMENTS IN PRESERVING WOOD. Dated February 8, 1868.

In order to preserve railway sleepers and other timber from white ants, Teredo navalis, dry rot, and decay from other causes, the patentee dissolves, in 50 gallons of boiling water, 10lb. of powdered potash, and 10lb. of powdered lime. In another 150 gallons of cold water he mixes 40lb. of sulphuric acid, and, afterwards, he mixes the two liquids together: this is compound No. 1. Again, he boils in an iron pot 50 gallons of crude petroleum, 40lb. of asphaltum, 30lb. of powdered lime, mixing in therewith, by preference, 20lb. of zopissa, and lets it boil until it ignites. As the zopissa can only be dissolved by fire, after half an hour's boiling he mixes therewith one pint of sulphuric acid: this is compound No. 2. He immerses the railway sleepers or timber in the liquid No. 1 for a quarter of an hour, or he coats them with a large tar brush, and dries them for a day or two afterwards. He also coats the sleepers or timber with a tar brush well on all sides with the composition No. 2 in a hot state.—Patent completed.

453 J. TANSLEY. IMPROVEMENTS IN APPARATUS FOR WORKING THE ROLLERS OF BLINDS, SHUTTERS, ETC. Dated February 10, 1868.

The object of this invention is to remove the need for cords and springs in the raising and lowering of blinds and of roller maps, and of chains in the working of coiling iron shutters, and to substitute therefor a simple and economical arrangement of mechanism which may be applied to operate the blind or shutter, or it may be two or more simultaneously. To this end the patentee employs, for the purpose of transmitting motion to the roller carrying the blind or coiling shutter, a screw spindle, somewhat like those used for hand drills, which spindle is provided with a traversing nut for giving it an axial motion that is transmitted by gearing to the roller. The invention is not fully described apart from the drawings.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Geographical Society (at the School of Mines, Jermyn street), 8.30.

WEDNESDAY.—Geological Society, 8.

FRIDAY.—Architectural Association.—"On the History of the Manufacture of Clocks, and the Structural Arrangements made for their Display and Preservation, with Practical Rules for the Guidance of Architects," By M. Digby Wyatt, F.R.I.B.A., F.S.A.

Trade News.

TENDERS.

BURTON JOYCE (Nottinghamshire).—For chapel and school at Burton Joyce, Nottinghamshire. Mr. J. Tait, architect:—

J. Wright and Son (accepted) .... £[illegible] 12

DERBY.—For Congregational chapel, Derby. Mr. J. Tait, architect:—

Stoddard (accepted) £1258

ELVASTON.—For the erection of steward's residence at Elvaston, for the Hon. the Earl of Harrington. Messrs. Stevens and Robinson, architects, Derby. Quantities supplied:—

Thompson	£1390
Wood	1350
Fryer	1270

KENSINGTON (Derbyshire).—For mission chapel, Kensington, Derbyshire. Mr. J. Tait, architect:—

Warner and Son (accepted) £262

LONDON.—For alteration, repairs, and decorations to 72, Grosvenor street. J. and E. Baddeley, surveyors:—

Clarke and Mannoch	£[illegible]	0	0
B. B. Sapwell	[illegible]	3	4
Scrivener and White (accepted)	819	0	0

LONDON.—For alterations, &c., to No. 7, King-street, Snow Hill. Mr. B. Tabberer, architect:—

Oatley	£615
Clarke	512
Young	495
Pearce	463
Larke	459
West	446
Walker	394
Bostel	382
Whittingham	365

LONDON.—For rebuilding Nos. 27 and 28, Monkwell-street. Mr. B. Tabberer, architect:—

Larke	£2387
West	2204
Turner and Sons	2076
Brass	1997
Pearse	1997
Browne and Robinson	1997
Prind	1935
Henshaw	1890

RAMSGATE.—For building a warehouse, &c., 59, Queen-street, Ramsgate, for Messrs. Vye. Hinds and Sons, architects:—

Hobbs	£1350
Goodchild	1180
Horne	1095
Harrison (accepted)	1075

READING.—For the erection of new Infant School for the parish of St. Lawrence, Reading. Messrs. Wm. and J. T. Brown, architects:—

Matthews	£712	0
Barnicoat	690	0
Sheppard (accepted)	634	10

READING.—For the erection of a house and shop in Broad street, Reading, for Mr. Batho. Messrs. Wm. and J. T. Brown, architects:—

Kendell	£576
East	566
Sheppard	55[illegible]
Carter	529
Clacey (accepted)	507

READING.—For the erection of a house and shop in Broad-street, Reading, for Mr. Hiscock. Messrs. Wm. and J. T. Brown, architects:—

Whiting (accepted) .... £[illegible]

SEVENOAKS.—For additions, &c., to a house, Sevenoaks. Mr. B. Tabberer, architect:—

Willshire	£3[illegible]
Grover	2[illegible]
Larke	242

STROOD (Kent).—For the erection of new corn warehouse at Strood, Kent. Henry Andrews, architect, Rochester:—

Wilkins and Son, Chatham	£1[illegible]	0
Baxter and Sa[illegible]man, New Brompton	1475	0
Ball and Co., Strood	14[illegible]	0

COMPETITIONS.

India.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

Melbourne, near Derby.—For designs for a new Wesleyan chapel. Mr. W. H. Adcock, Melbourne, near Derby.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

Hastings.—November 16.—For the purchase of ashes' cinders, marine stores, and refuse of every kind. G. Meadows, clerk, Local Board of Health, Hastings.

Leicester Waterworks.—December 8.—For the construction of a large storage reservoir, &c., and for the erection of an engine and boiler house, and other works. J. H. Williams, secretary, Waterworks offices, Bowling Green-street, Leicester.

St. Mary Church, Torquay (Devon).—November 19.—For the erection of new gasworks in the Barton-road. Grant Wollen, clerk to the local board.

Penzance.—November 28.—For the improvement of the harbour of Mousehole, in the parish of Paul, near Penzance, in Cornwall. Rodd and Cornish, solicitors to the Commissioners, Penzance.

Rochdale.—November 24.—For lighting the new townhall with gas. T. Mellor, town clerk.

Rochdale.—November 24.—For warming and ventilating the new townhall. T. Mellor, town clerk.

Tower Subway Company.—November 30.—For the construction of lifts. Mr. P. Barlow, engineer, 26, Great George-street, S.W.

Trinity House, London, E.C.—For the supply of dressed and scappled granite for new lighthouse at Longships rock. R. Allen, secretary.

Market Drayton.—November 11.—For the construction of a cattle market. E. E. Warren, Market Drayton.

St. Luke's, Middlesex.—November 11.—For certain repairs and alterations to St Luke's Church. Vestry clerk, Vestry Hall, City-road.

Bradford.—November 16.—For the erection of a large fireproof mill and engine house in Lumb lane. Lockwood and Mawson, architects, Exchange, Bradford; 10, Lincoln's Inn Fields, London.

Bradford.—November 23.—For the erection of thirty shops in Godwin-street. Lockwood and Mawson, architects, Exchange, Bradford; 10 Lincoln's Inn Fields, London.

Bradford.—November 16.—For the erection of a new wing to the Hydropathic Establishment as West Rhydding. Lockwood and Mawson, architects, Exchange, Bradford; 10, Lincoln's Inn Fields, London.

Ilkley.—November 12.—For the erection of an hotel and boarding house, near Wells road. Thos. Ambler, architect, 9, Park place, Leeds.

Leeds.—November 14.—For the erection of new school buildings, in connection with the Methodist Free Chapel at Farsley. C. S. and A. J. Nelson, architects, Albert chambers, Park row, Leeds.

Wolverhampton Union.—November 13.—For alterations and extensions to the Wolverhampton Union Workhouse. Edwin Pritchard, Clerk to the Guardians, Wolverhampton.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

George Bowtell, Leyton, Essex, builder, November 19, at 12—Charles Parks, Foley street, Marylebone, builder, November 19, at 1—Henry Smith, Johnson-street, Nottinghill, painter and glazier, November 19, at 2—William Woolley, Twickenham, builder, November 24, at 11—John Allen, Avenue road, Camberwell, smith and engineer, November 17, at 12—Martin Homan Bourke, Richmond, Surrey, railway contractor, November 17, at 1—William Few, Hargrave Park road, Upper Holloway, builder, November 12, at 12—George Huckle, Great James-street, Bedford-row, builder, November 17, at 12—Thomas Vincent Lee, Millman-place, Bedford-row, civil engineer, November 12, at 1.

TO SURRENDER IN THE COUNTRY.

Samuel Benn, Great Horton, plumber and glazier, November 13, at 9.30—Agar Gardner, Towlaw, Durham, joiner, November 16, at 4·30—William Fletcher Ireland, Bolton, slater and felt merchant, November 18, at 10—William Clamp, Leicester, painter and builder, November 17, at 11—Thomas Taylor Hilton, Blackburn, bricklayer, November 10, at 11—Archibald Kane, Carlisle, joiner, November 13, at 11—George Ravenscroft, Crewe, Monks Coppenhall, builder, November 11, at 11.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

November 25, T. W. and J. Stears, Hull, engineers—November 18, W. Wilson, Bulmans Village, near Newcastle-on-Tyne, builder—November 20, T. G. Jenkins, Liverpool, builder—November 20, W. Briggs, Halifax, bricklayer—December 17, S. Denton, Regent's Park-road, Finchley, builder—December 14, R. Hall, Kentish Town-road, carpenter—December 17, F. Nash, Alton, plumber—December 17, A. P. Jones, Edgware-road, builder—December 17, W. White, Poole, builder—November 20, J. Cobden, Pooles Park, near the Seven Sisters-road, Holloway, builder—November 30, J. Powell, Forest Gate, builder—November 16, R. Watkins, New Kent road, plumber—November 16, T. Fergusson, Wharf, Amberley-road, Paddington, brick merchant—November 18, J. W. Crook, Langley, Bucks, carpenter—November 18, T. Morgan, Testerton-street, Notting-hill, plasterer—November 20, T. Lane, Watford, builder—November 26, W. H. Litherland, Manchester, timber dealer—November 11, J. Lockett, Hanley, brickmaker—November 6, M. Mansell, Wellington, Salop, bricklayer—December 11, Z. Stebbing, Bury St. Edmunds, painter—November 18, W. Shetton, Stonesby, Leicestershire, lime burner—December 3, D. Ward, Brighton, carpenter and joiner.

PARTNERSHIPS DISSOLVED.

Hudson and Varley, Leeds, timber merchants—Moore and Collins, Wilton road, Pimlico, and Penge, builders—Wood and Sons, Worcester, timber and slate merchants—Nichol and Derbyshire, Liverpool, timber merchants.

THE BUILDING NEWS.

LONDON, FRIDAY, NOVEMBER 13, 1868.

ARCHITECTURAL ASSOCIATION.

WE took occasion recently to consider the position and prospects and to review the programme of the proceedings of the Royal Institute of British Architects, and also to refer to the address of its president. We now propose to do the same with regard to the Architectural Association, the session of which was opened by a *conversazione* of its members and their friends on Friday evening, October 30.

In the first instance we congratulate this junior body of the profession, as we did its senior, upon a continuous and steady increase in its numbers. The list of these just issued shows that the association now consists of no less than 392 members, of whom 105 were enrolled during the past year. This fact is most gratifying and speaks for itself as to the appreciation with which the institution is regarded. It might at first seem strange that the Institute should fail in attracting these young men into the ranks of its students, and that both bodies must suffer somewhat by their apparent disunion. Self-help, however, has advantages, and self-government has attractions, while youth and age have many points of difference; so that on the whole we question whether the arrangement as it stands is not better than any possible fusion of the two. The utmost harmony now prevails between them, and the younger institution often refers to the elder for assistance on various matters, and is aware that it may always reckon on its sympathy and support. Evidence of this cordiality is adduced in the list of officers of the Association; thus the name of the president for the year is followed by the mystic initials F.R.I.B.A., while A.R.I.B.A. is attached to those of the two vice-presidents, the two honorary secretaries, and to seven out of the ten members of committee. A glance at the description of the proceedings shows that some of the objects and wants of the Association are such as could not be rendered compatible with those of the Institute. For instance, with regard to its library, it is set forth as being the *only lending library in the profession;* as such its utility to students cannot be over-estimated, and yet it would be simply impossible to combine such a feature with the character of the library of the Institute, the valuable works in which could not be so exposed to the risks of injury or loss. The *Syllabus of Papers* for the entire session, issued at its commencement, bespeaks great energy on the part of the secretaries, and must conduce greatly to the deliberation with which the papers are prepared and discussed.

The *class of design* has always been a distinctive and most useful feature in the proceedings of the Association, and the sketches which are the result of its labours are annually seen at the Architectural Exhibition, and their value has been repeatedly acknowledged; but the *sketch book* is a comparative novelty, and shows even a greater spirit of enterprise. It consists of drawings and sketches of ancient buildings or details, contributed and lithographed by the members. It is published in monthly parts, the sketches being selected by a committee. One volume has already been issued and reviewed at length in our pages, and highly though we were able to commend it generally, we notice an improvement in those parts which have been published since. There can be no doubt that by this work the Association will do good service and gain much credit.

Another valuable class is that of *construction and practice*, "formed in order to assist the members to obtain a knowledge of the practical part of their profession by means of an organised system of mutual study." The course adopted is as follows:—A number of questions are issued bearing on the subject to be treated of. The members are required to furnish replies to these in writing. One of these is selected and read out at the meeting, and the remainder are compared with it. The results are then discussed, and the methods by which they have been arrived at explained and illustrated by sketches on the blackboard. We are not surprised to find by the report that "this procedure has been found to work well, and that a large amount of information has been acquired and disseminated during the existence of the class."

The class for *figure drawing*, the object of which is defined to be "to study the drawing of the human figure with special reference to its bearing on architecture," is one of the greatest value, for the establishment of which the Association deserves great praise. The want of the opportunities it affords has long been felt by many of the more art-loving members of the profession, and we trust soon to see its practical results in advanced artistic power on the part of the rising architects. A *water-colour class* under the guidance of Mr. Aaron Penley, the arrangements for occasional visits to ancient and modern buildings, and a goodly list of prizes offered for the most successful efforts in the various classes above described, show a thirst for knowledge and a determination to attain and profit by it which cannot fail to command success.

We are, however, by no means of opinion that these praiseworthy endeavours on the part of the students to help themselves at all absolves their elders from the duty of assisting them. Such efforts in the limited time which young men can devote to these pursuits can be but desultory. "Technical education" in architecture is still the sore need of the profession, and we do not intend, therefore, to relax our endeavours to raise the cry, "Educate! Educate!" to some purpose.

The necessity for such an appeal, notwithstanding all that has been attempted or is contemplated by the Association, was forcibly put by its president, Mr. White, in his able address, a summary of which we published in the last number of this journal. "Education," he remarked, "ought to be systematised, and to a considerable extent centralised, in the same manner as the higher branches of education are centralised in our universities," since, as he pointed out most clearly, "the very idea of *mutual* education implies in some degree a weakness of system and of position but one degree removed from *self* education;" and he remarked with truth that "it was not quite free from the pernicious effects almost inseparable from any system of licentious self-government." To impress on his hearers the warning conveyed in the words we have quoted was the object throughout the greater portion of Mr. White's address, and, being well meant, it was well received, although naturally the members of the Association might not be supposed to see the defects of their system as clearly as its merits, and might fairly plead that none other has as yet been established for them.

There are doubtless many difficulties in the way of founding the education for architects which is needed, and the first question is by whom should it be done? Perhaps Government can hardly be expected to take one particular profession under its wing, and the only hope for State aid in the matter is in obtaining a fair share of consideration for architects in any general scheme, such as that for "Technical Education," for which the Society of Arts is agitating. It is true that the Department of Science and Art undertakes the tuition of designers for manufactures in the schools at South Kensington and in the provinces; but a part of the programme of the proceedings of that body has always appeared to be the systematic ignoring of architecture and architects, so that it is quite useless to look for help in that direction. The Royal Academy, which is independent of Government, provides for the education of painters and sculptors, and does just so much nominally for architects as to impede any other effort of the kind, in the same way as by the modicum of space it allows for architectural drawings it injures any other architectural exhibition.

The Institute has not the means to do more than offer prizes or set on foot examinations to test the results of education already obtained elsewhere; and this, as is evident by the failure of its "voluntary examinations," is, in fact, putting the cart before the horse. It can, however, head the agitation for what is so greatly needed by the profession, and is, we understand, now engaged in resuscitating a committee of representatives of various societies, to whom was committed some time since the consideration of a scheme for establishing "a school of arts accessorial to architecture," suggested by Mr. Scott. We learn, also, that Mr. Joseph Clarke, on the part of the Architectural Museum, has proposed that the new premises of that institution might be made available in connection with such a school. Another hope is held out by University College, where Mr. T. Hayter Lewis is the Professor of Architecture, and has for some time been endeavouring to set on foot "a scheme for the extension of the study of fine arts as a branch of general education for all classes." The late Sir Felix Slade's bequest of £50,000 for endowing professorships and scholarships for students of art it is hoped may assist this effort, and, if so, here is another nucleus to which a proper system for architectural education might be attached.

Of course any such system could not supersede the necessity of the present one of pupilage. It would only be supplementary to it, and intended to supply that theoretical knowledge for which the routine of office duties does not allow sufficient opportunity. We think, however, that considerable modifications might be made with advantage in the relations between masters and pupils, with the view of ensuring to the latter the proper time to avail themselves of the advantages for which we are pleading. Technical education should unquestionably commence long before a student enters the office of an architect, but it should be continued in connection with his studies there, so that the theory and practice of the profession might be learnt simultaneously. It is satisfactory to find that there is so considerable an amount of agitation in progress with regard to this important subject, and it may be confidently hoped and expected that before long, by the agency of one or other of the levers which are being used to attain the desired object, some practical good will be effected. In the meantime we would wish to encourage the laudable efforts of the Architectural Association to attain the same end for themselves. Indeed, whatever may be effected for them outside of their own body, their operations will not be less needed; while the enthusiasm which is one of the best results of their mutual studies cannot otherwise be supplied. Enthusiasm is, in fact, at once the cause and the effect of the very existence of the Association separately from the Institute, and the secret of its well-deserved popularity among the junior members of the profession.

LONDON LAMP-POSTS.

STREET lamps, lighted with gas, have been in use in the principal streets of London, Edinburgh, Glasgow, Manchester, Birmingham, Liverpool, and other great cities since the year 1821. Now, in half a century many improvements have been made in various branches of art and industry, but they have not affected the lamp-posts. It is

true that by the recently introduced method of lighting the gas by means of a torch time and labour are saved, and the proverbial despatch of a lamplighter no longer means a feat of almost acrobatic agility performed at intervals of a few seconds. But, in the form of the posts bearing the lamps, no improvement has been made since the year 1821. The earliest lamp-posts are to be seen in Whitehall, the latest in Park-lane.

At the present time, when we may expect many improvements in our street architecture, for we firmly believe the authorities are doing their best according to their dim lights, the beauty even of so utilitarian an object as a lamp-post is no unimportant matter. Having been at much pains to examine them in various parts of the metropolis we have arrived at the conclusion that it is high time to change old lamps for new and new lamps for newer. Let us commence at the Royal Exchange. These are suitable as accessories to a public building, but are not fit for ordinary street use. They are heavy and expensive, bound with the fasces of the Roman, inscribed with the S.P.Q.L. of civic authority, and surmounted by the civic cap, borne on the civic cushion, with little civic tassels hanging at the corners. At the Bank of England there are no lamp-posts, but elegant brackets projecting from the wall at right angles supported by a curved strut. They harmonise with the character of the building. Opposite the Mansion House are three posts, each supporting five lights. These show a good deal of design, but very little proportion. There is no doubt the designer took much pains with them, but the lamps are too small and the posts are too large. In the new lamps in Hyde Park and elsewhere this error at least is avoided. The three lamps on the obelisk in Moorgate-street, bearing date 1863, are certainly of better design, though they are placed somewhat high. At the Post Office the standards form part of the surrounding railings. They are heavy even as accessories to Grecian architecture. In the square of Bartholomew's Hospital four lamps have very recently been placed. They look very well in that situation, but are too fine for everyday street use, making the ordinary lamp-posts which still remain in the square to look very shabby indeed. At the Cannon-street Station, where something above the average might be expected, one is doomed to disappointment. The lamp-posts consist of a sort of base or pedestal, something of the same form as those of the ordinary street lamps, surmounted by a shaft twisted into a spiral in the Gothic manner. The effect is exceedingly bad, and they show no indications of artistic taste on the part of the designer, but the glass globes are of good form and the lights are placed sufficiently low. The lamps at the Charing Cross Station are similar in every respect to these. Returning to lamp-posts of more importance the latest are to be seen in the quadrangle of the new Foreign and India Offices. They are literally covered with ornament, either cast in the solid or screwed on in little bits. This ornament is of a most trumpery character, but is contrived with strategic ingenuity to catch and tear any textile fabric with which it comes in contact. A wooden post well provided with tenter-hooks is not more to be avoided than these evil posts. Incidentally it may be mentioned that owing to improper construction nearly every lintel and sill in the basement story, of the quadrangle at least, is cracked through and through. The settlement of the building was the cause, but the *causa causans* was their being placed in position too soon—in short, before the piers had settled. For this there can be no shadow of excuse, and the fact of its occurrence is disgraceful to all concerned. The most ignorant mason or bricklayer in London must have known the inevitable result. The lamps on the piers in Palace Yard do not come under the head of lamp-posts, and, therefore, need no remark, but the new posts in the green and in front of the peers' entrance, &c., call for observation. They are simply the worst to be found in all London. The lower part positively consists of buttresses—buttresses in cast iron!—craftily devised for offensive purposes, while the upper part or shaft is twisted in the approved manner to give the ignorant the idea that much Gothic character is given. If these posts were in a less important situation it would not so much matter. Of precisely the same character, but of larger size, are the four standards in the Victoria Tower. They are more *costly* than cast iron itself, and it would be difficult for human ingenuity to combine in one work more bad lines. The bases are too large, the shafts too tall, and the lamps too small. The bases are very much in the form of the struts which support the flagstaff on the top of the tower, which is equivalent to saying that they could not well be in worse taste. Whoever the author we assure him, from motives of pure compassion, that he will never be a man of metal. At all events, let him beware of lamp-posts. From the green let us return to the steps leading from the India House into St. James's Park. On these steps are four lamps of really elegant design, as is all the metalwork of this building, with the exception of the ill-designed and worse-placed lamp-posts in the quadrangle. Let the visitor by no means overlook these steps. Proceeding along Broad Sanctuary the standards on the rail of the Westminster Palace Hotel are worthy of observation, but they have great advantages over the ordinary street lamp: the difficulty of a suitable base is got over because they are already sufficiently elevated, and they may besides be of a much more ornamental and delicate character than befits a street lamp-post. They would, however, have a better appearance were they somewhat higher. The same may in a still greater degree be said of those at the Grosvenor Hotel, which are positively stumpy. We are curious to see what the lamps on stone piers which are to adorn the green immediately opposite will be like. In Grosvenor-place up to Hyde Park Corner a very ambitious style of lamp-post prevails. They are at least eighteen inches square in the base and are much too lofty, and, like almost every lamp-post in London, are not upright. At Hyde Park Corner there are two lamp-posts in the centre of the road, each bearing three lamps. They do not even correspond, one being entirely of iron and the other set on a stone pedestal nearly six feet high. This latter was erected in 1840. In front of the arch and entrances to the park are ten lamp-posts of imposing proportions. Unfortunately, though of fair classical character and appropriate to the structures to which they belong, they are tripods on plan, and a tripod can only look well when seen directly at right angles to one of its faces or one of its corners. From any other point it is a lop-sided composition. The new lamps in the park next claim attention. They are cast by Messrs. Ching and Co., Castle-street, Long Acre. The designer no doubt intended them to be very ornamental, but they have grave faults. The base or pedestal is very large, and its projecting corners are objectionable if not dangerous. The globes are an improvement on the usual street lamp, but Mr. Lenzberg, of 486, Oxford-street, has invented something which in our opinion is still better. It is well known that all the light which passes through the lamp in an upward direction is lost, and no successful means of reflecting it down on to the pavement has hitherto been found. Mr. Lenzberg's lamp consists of two parts, a half globe covered by a hexagonal top of enamelled glass in metal frame. This effects the purpose. Eight or ten of these lamps may be seen in position opposite Mudie's library. They are set on the old posts, which are much too high, and they are made to hang over the pavement; thus there is nothing whatever to cast a shadow anywhere but on the road, where it is almost imperceptible, less indeed than is that cast by the frame of the ordinary lantern. Opposite the Marble Arch are two posts, each supporting a pair of lamps. They are stiff beyond measure, and, large as they are, they do not maintain the perpendicular. In situations like these something handsome is required, such as the posts in Blackfriars-road and the Borough, or the new one in Holborn where Middle-row once was. In Regent-street the lamp-posts are very bad indeed. They are enormous at the base, are bound with fasces having spear-heads at the height of about six feet, which are for the most part broken off. When the quadrant was altered to its present appearance a few lamp-posts of better design were put up. There is some attempt at decoration, but there is too much repetition of form, and the lanterns are too small and placed too high; ten feet is the proper height for the burner. In Regent Circus South, where something ornamental might have been expected, there are two lamps which do not match. One of them is a "fearfully and wonderfully made" affair, with a red glass globe a-top surmounted by a flying Mercury bearing a small ball of silvered glass. This lamp indicates the proximity of a telegraph station; the other is not so ambitious and is in every way unremarkable. In Waterloo-place the Crimean Memorial is flanked by two posts of curious design, wreathed with leaves emblematical of military virtue. From a little distance these wreaths have every appearance of being very large snakes trying to climb the posts. On the balustrade of the United Service Club may be seen some very well conceived posts with small heads and spreading bases. The two in front of the Reform Club, like those of the Traveller's, are very handsome, but the head throws too much shadow. At the Carlton the lanterns are too small and the bases very commonplace. The small standards on the parapet of Trafalgar-square are very elegant, but we cannot say as much for the four large ones especially erected for burning the Bude light. Having now found fault with almost every lamp-post in London it may be expected that we should give some idea of what a lamp-post should be. The accompanying sketch represents such a post. With a base fifteen inches square to give it a chance

to stand upright—which scarcely one in a hundred does—it should gradually taper to a diameter of about four inches at the height of four feet six inches from the ground. It may be plain or fluted. There should be no fillets or horizontal lines of any kind, as the post would be certain to break at those places if subjected to a blow. The head should be small so as not to cast a large shadow. Such a post as this offers little obstruction to foot passengers, has no sharp corners, is strong, and inexpensive. The form of the reflector above the lamp might be improved, but we profess to give merely a plain street lamp. The lamp is that patented by Mr. Lenzberg, and is similar to those which he is about to place experimentally on the Thames Embankment.

ROOF COVERINGS AND EXTERNAL DESIGN.

IT is singular that while there is only one part of a building in town architecture which the rain may be trusted to keep constantly clean this should be the very part on which least design is usually expended. Decoration in abundance, or rather in superfluity, is lavished on the walls, though everyone concerned knows that it will soon be almost obliterated by dirt, but the roof, which remains unchanged year after year, is passed by unnoticed. It is true that the best examples, at least in the Gothic style, seem to show that decoration in the roof covering should be subordinate to that in the structure beneath. It is easily carried to excess, and plain surface is just as valuable in slating, for example, as in walling; still the general tendency hitherto has been rather to neglect this part of the design than to over-do it, and in many elaborate structures the part above the cornice seems quite unworthy of that below it. How effective it may be made in point of form the new buildings in Pimlico, amongst others, sufficiently show; but our present purpose is less with general form than with roofing materials. These of course are divisible into three main classes—metals, tiles, and slates. Of the first class, lead and zinc are the only ones much used in this country; copper is still occasionally employed, and tin plate very rarely, if at all. As cheapness is nowadays considered much more important than durability, it is natural that zinc should to a great extent be superseding its rivals. How long, even under the most favourable circumstances, it will resist the action of a London atmosphere is yet uncertain. Sulphuric acid, which appears to be the chief agent in the decay of our building stone, dissolves it rapidly, and the sulphate produced is too soluble to form a protecting surface to the metal beneath. It is, therefore, scarcely to be hoped that even with the most careful treatment zinc will prove a very desirable material for town architecture. From an artistic point of view this is, perhaps, to be regretted. A metallic covering gives facilities for many forms of roof which are both convenient and picturesque, for which slate would be unfitted. It has naturally, by reason of the rolls or other junctions of sheets, more variety of surface and more strong and muscular lines. It is not a smooth texture less plane like slating, it is broken up by light and shade. And this character can be increased to any extent that is desired. Cast and stamped ornament rise out of constructive forms almost as a matter of course. Edges can easily be formed into characteristic patterns, metal crestings and finials are obviously appropriate, and colour can be added without difficulty. The leadwork of the Middle Ages—or what little of it remains—is most suggestive on these points, but the misfortune is that we have become too economical to perpetuate the system. Lead is too costly for us, but even in using zinc something may be learned from ancient practice.

It is a principle more generally acknowledged than adopted, but still a most important one, that the designer should use every material he deals with so as to bring out its distinctive properties. Those of a metallic roof covering, as we have seen, are chiefly in the projections of surface appropriate and even necessary to it. But while its design will thus be mainly based on form, that of slating will be far more largely affected by colour. Decoration here has, indeed, been often attempted by cutting the edges of the slates into fanciful shapes, but the result seldom repays the labour involved. Coloured patterns, it is true, are not always more successful, but they are, at any rate, more capable of being made so. Unfortunately there are but few varieties of tints attainable. There is the ordinary bluish-grey of various shades, the pinkish-grey or mottled, and the green. The last has a doubtful reputation for durability, and the very dark grey a still worse one. Green slates, too, if good, are expensive, and being generally supplied of a slightly different size from the blue slates of the same denomination, further expense in cutting is needed to make them work together. But, in spite of these drawbacks, we have hardly anything to compete with them for use in patterns. Almost any of the shades of grey will do as a groundwork: the mottled one gives, of course, the greatest contrast, but not always the best effect. As, however, it is impossible to surround the pattern with a dark outline, it should always be lighter than the ground on which it is placed. Flat ornaments darker than the surface on which they lie usually require a border of some kind to keep them distinct. Where Countess slates are used, the scale of the patterns, again, is so great as often to be injurious to that of the building. They are so large as to detract from its size, and they fail to harmonise with the details, for example, of the brickwork. This is a difficulty to be met in different ways in each particular case. A smaller description of slate may be employed, or narrow bands and only the simplest forms of decoration may be adopted. But, in any case, delicacy and moderation are needed. There is an old rule which recommends people always to leave their dinners with an appetite; an analogous one would be equally good in artistic matters. All works of art should be such that spectators leave them wishing for more rather than satiated by too much enrichment; and the maxim was never more applicable than to the subject now in hand.

The third class of roof covering—that of tiles—combines, in some respects, the characteristics of both the preceding ones. It admits of nearly as much variety in form as metal, and of much more variety in colour than slating. But whether it would be wise to push both these characteristics to an extreme at once is more than doubtful. Intricacy of form needs simplicity in colour to make it intelligible, and the opposite course leads to confusion, not to excellence. Following this principle, plain tiles may properly be relieved by differences of hue, while pattern tiles will do better in uniform or merely graduated tints. Even in the first species slight contrasts are usually the safest. Every one must have noticed the picturesque effect which often arises when old and newer tiles are worked in together, even with no special design. A harmony and excellence of tone are manifested which glaring contrasts never produce. Plain tiles are in many respects preferable in appearance to slates, at least for buildings of an unpretending class. Their slightly curved outlines and thick edges give them far more picturesqueness than can be gained by straight, wiry lines of the alternative material. Practical considerations, however, such as their weight and their absorbent quality, have in great measure diminished their use; and the ground they have thus lost will probably never be regained. But with other forms of tile the case is different. Amongst the developments of the *pantile* principle, both here and in France, there are several to which no objection, except that of expense, can be raised. Instead of exhibiting a simplicity bordering on rudeness, they are the latest advance in mechanical ingenuity as applied to roofing. As regards design, most of them would be improved by being less pretentious, but in construction they have much to recommend them; and the broken up surface which they naturally give is at any rate capable of being turned to good account artistically. Most of the patterns hitherto brought forward show, indeed, such strongly-marked and heavy lines as to agree better with Italian or Romanesque than with Gothic; but there is no reason why the same principle should not be carried out so as to suit any style of architecture, and whatever class of roof covering we may have to do with thought and invention will not be wasted on it. Town architecture has long been half-ruined by the attempted concealment of its roofs. Their disguises have been unpleasant enough when seen from below; but now that their complete deformity is thrust on the view of every passenger by a suburban railway, it is surely time that they were made a little fitter for the close inspection under which they have been brought.

WORKING PLANT AND APPLIANCES.

HUMAN invention and ingenuity are ever on the stretch to keep pace with the contingencies that are daily and hourly occurring, and are the inseparable attendants of an age of reason, enlightenment, and national education. No sooner is one improvement patented and given to the public than another springs up superior to its predecessor, and after that another, and so on until man's inventive faculties are racked and the powers of imagination strained to the utmost to meet the ever-increasing demands upon the fertility of its resources. Notwithstanding that the aid of machinery has been called largely into requisition in the construction of engineering and architectural works, yet many of the processes and operations still continue to be carried on by manual labour. Earthwork, as excavating and filling are usually called, is still nearly universally performed by hand. The old system of laying down temporary rails, filling the "lorries," and tipping them over the "tip head" is still practised, and will be for a long period to come. Where the excavation takes the shape of a tunnel special machines are used, as in the case of Mont Cenis, which is an example upon the largest and most successful scale that has ever been attempted. A marked improvement was visible in the construction of engines, movable cranes, and other mechanical appliances for raising loads at the recent "Exposition," in comparison with the specimens exhibited at previous international displays; they were much simpler in construction, better finished with respect to fitting and workmanship, more practical in design, less costly, and better adapted for rapid manipulation, and less likely to cause accidents and mishaps among those working them. Except in comparatively insignificant instances, the old system of scaffolding for house building is completely obsolete. Contrast the methods at present employed in the erection of the new mansions on the estate of the Marquis of Westminster with the more ancient system, wherein round larch and fir poles and rope lashings formed the prominent features. We replace manual labour in what might be termed the transference of materials by the agency of movable cranes running upon strong timber traverses; and in this respect our system, as a whole, is superior to that of our French neighbours, who admit the superiority in an economical point of view even if they are disposed to question the scientific or constructive bearings of the matter. England has always been celebrated for the solid and durable character of its masonry, and it must be acknowledged that our last great work, the Thames Embankment walls, fully sustains the national reputation we have acquired. Prussia is, perhaps, the only continental country that can excel us in stonecutting, and the manner in which her workmen can turn out the beautiful Silesian marbles, cut and polished, either by hand or machinery, is only known to those who saw the specimens exhibited at the Paris Exposition. There is no country where the erection of buildings, so far as modern inventions and conveniences are concerned, has made so little progress as France. Notwithstanding that there are abundance of more favourable appliances at hand, she continues to employ the ancient methods in spite of their slowness and cost. Unless her architects and engineers effect an alteration for the better, they

will find themselves in the background. Neglecting the consideration of those instances where the aid of machinery is called into play, we have made an immense improvement in the treatment we adopt for structures of less significant pretensions. The rapidity with which we erect light and strong scaffolding for the purpose of repairing the frontages of old buildings; the ready and ingenious devices for raising the materials required; the facilities at hand for underpinning arches and putting up centreing for bridges, and a host of other contrivances evince the march of progress in this particular branch of constructive art. It must not be supposed that other continental nations have exactly followed our example in these matters. One especial point in which there is a marked distinction between us and them is in the substitution of iron for timber. Among ourselves this is now almost universal. An engineer would never dream of erecting a timber bridge except upon a scale of the most trifling character, nor, in fact, were it intended for railway traffic, would the Board of Trade sanction it. Cast and wrought iron joists and beams are now the ordinary supports in warehouses and large buildings, to the almost entire exclusion of timber. The case is otherwise in France, where heavy balks are still employed in situations that we should now never think of their occupying. Recently iron wire has been used there with great success instead of ropes for scaffold fastenings. From very early times the Italians have been in the habit of adopting a peculiar description of scaffolding in which very short timbers are used, and the erection of which is carried on with extreme rapidity and considerable solidity. It is quite possible that if this system were modernised, and received the benefit of all the recent improvements and modifications, it might prove a very valuable one.

It might be supposed, from what has been stated respecting the substitution of iron for timber, that the trade of the carpenter had declined, and had, in fact, become merged in that of the smith. To some extent this supposition is probably true, but not to a degree sufficient to affect the absolute earnings of the former. Permanent iron constructions of the present day demand an amount of carpenter's work for temporary purposes far exceeding what was required for the permanent timber erections of bygone times. Let anyone take a glance at the forest of piles, uprights, horizontal trussing, bracing, strutting, and centreing, that obstruct the river at Blackfriars, and it will be more than sufficient to assure them that timber and carpentry still play a very considerable part in engineering and architectural structures. Machinery has been established on the most improved system and on the most extensive scale for fashioning the timberwork intended for the interiors of houses; sawing, planing, mortising, tenoning, and all the other operations once performed solely by hand labour, are now accomplished by the agency of machines. It is rather curious that the principal railway terminus in Munich was one of the first instances abroad where all the timbers were prepared by machinery. Germany and our own country were the two foremost in availing themselves of the aid of steam power for this purpose. The real merit of the substitution of machinery for manual labour is undoubtedly due to the Americans, and in their case was a practical illustration of the old adage, "Necessity is the mother of invention." From a scarcity of manual labour, an inconvenience that all young countries suffer from, she was obliged to invent some means of accomplishing by machine power what was effected in more populous countries by hand labour. It is often said that the Americans invent, but we improve, and there is much truth in the remark. The reason is easily found, and the validity of the observation confirmed. The Americans have not the time to perfect any invention; they are daily, almost hourly, in want of it, and are compelled to utilise it before it has received that finish and those nice adjustments which in reality constitute the whole mechanical beauty of the machine. When the crude material comes to us we have leisure to examine it; and it, therefore, receives from us that remodelling and final improvement which the urgency of the case did not admit of in the land of its birth.

OUR ARCHITECTURE.

In his inaugural address delivered recently, Mr. F. Horner, the newly-elected president of the Liverpool Architectural and Archæological Society, made some remarks on the present state of our architecture likely to be interesting to all, and instructive to many of our readers.

If, said he, our architecture is a compound of Greek and Roman, of Italian and French Renaissance, and Gothic, is not our language equally compounded of, and derived from, all these sources? To the Greek, the Latin, and the Teutonic races, and even to modern France, how much are we indebted for its richness, its fulness and perspicuity! The comparatively contracted mental development of the rude Anglo-Saxon required, no doubt, a very simple form of speech wherewith to express any ideas he might wish to clothe in words; but as civilisation advanced, the science of language naturally became more complicated, and we find ourselves now supplied with an ample vocabulary, borrowed from all the foregoing sources, wherewith to give utterance to our thoughts. If in some particulars this fusion of tongues and dialects may lack the grandeur of simplicity which some original languages possess, it at least affords other advantages—of being full almost to redundancy, and of forming a very perfect channel for the expression of intricate ideas We do not, because we possess such a multitude of derivative words, therefore declare the English language to be effete; but, on the contrary, accepting its mixed character as an almost necessary result of the passage of time and our knowledge of the past, we admit at once that it is admirably suited for our state of high intellectual culture. So with our architecture, accumulated as its knowledge has been from the lights of past ages. The researches of the archæologist and our intercourse with foreign countries have legitimately placed this acquired experience of generations within the grasp of the practitioner of the nineteenth century, to be interpreted and adapted freely by him, and, with the additional resources which a man of talent ever has at his command, from the exercise of his own individual invention, to be used for the purpose of meeting the complex circumstances and requirements of a refined age; and thus treated as an art, it is still a living and progressive one.

Many and great as are the facilities and appliances which attend a state of high civilisation in the culture of science and taste, it may well be doubted whether, in respect of the latter at least, these acquisitions are unmixed benefits. May we not, on the contrary, often find in the works of our forefathers much of simplicity, of unity, of repose and association, which our more modern designs frequently lack, but which, after all, are very important elements of power? One of the characteristics of our own day, no doubt, is that scientific knowledge and mechanical skill have advanced in a much greater ratio, even within our own recollection, than artistic feeling or taste; and there seems to be some danger of the spirit of the latter being almost merged in the general utilitarian tendency of the age. It behoves us, then, to combine in keeping alive some spark of regard for the poetic by every means in our power; and I cannot think that for the attainment of this object it is wise with regard to any art, not even of the art architectural, constantly to crave after some new thing.

Architecture, like its sister arts, has a noble history to look back upon; and her development has been as gradual as the lapse of years, upon whose centuries it is written in living stone.

The growth of the architecture of Greece was the work of hundreds of years; and it slowly arrived at its perfection by the patient and careful study of harmony of proportion and beauty of form; and the same truth is to be learnt from the history of the rise and progress of Gothic art.

"Beauty," says a writer in "Frazer's Magazine," "is everywhere, unnecessary, useless beauty, throughout earth, water, air, and the infinite of space; and everywhere developed, in metre, in balance, in rhythm, in symmetry; the grand original Poiesis."

There is a great truth in this quotation; but such words as "unnecessary" and "useless" can never, in their ordinary acceptation, be applied to any works of nature.

That elements of beauty everywhere exist in nature, supplying no physical want, and ministering to no material necessity, is, I think, the most striking argument which can be adduced in proof of the vast importance of the place assigned it in the economy of creation as a moral and intellectual agent for the mental use of man; and thus viewed, every trait of beauty to be found in the universe is in the highest sense both necessary and useful.

Founded on an innate love of the beautiful, that subtle and delicate mental gift called "feeling" is in fine art the key to truth; and all that is lofty, refined, and consistent is perceived through this faculty. To him who possesses it not, I fear it can never be supplied by reason or philosophy.

There are men to be found moulded much upon the model of our iron age, who seem ever desirous of dragging down the standard of taste to a level with their own perceptions; possessed of no sensibility themselves, they ridicule its presumed assumption by those who do possess it; ignoring the probability that the deficiency may reside in their own prosaic and matter-of-fact brain, and not in any affectation of the poetic mind of the artist. To such spurious connoisseurs as these we may reasonably assume the poet laureate to have addressed his objurgation:

> Vex not thou the poet's mind
> With thy shallow wit,
> Vex not thou the poet's mind.
> For thou canst not fathom it.

The well-informed art critic who is philosophical in thought, and moderate and judicious in the statement of his opinions, is entitled to our respect, and is often a very valuable coadjutor to the man of genius in the attempt to forward their common cause, and to raise the tone of the public mind to something like an appreciation of questions of taste. But it behoves these gentlemen to be careful that, even when perfectly honest and unbiassed in the treatment of their subject, they do not fall into the error of conventionalism, both in idea and expression; an offence which they are wont to visit somewhat heavily upon the heads of any whom they may deem amenable to it.

The opportunities which the modern architect enjoys of exercising his talents upon works of national importance or of great magnitude are, I fear, few and far between. But if this be denied him, yet many occasions must occur in the course of the practice of a lifetime, which shall enable him to illustrate the true principles of his profession, and leave enduring monuments of his skill, which shall influence the future development of his country's architecture in long years to come.

No branch of art so materially affects the health and well-being of a people as architecture, and with the return of commercial prosperity let us hope that the work of converting our formerly most prosaic and unartistic street designs, already so ably begun, into erections worthy of our day, may yet more rapidly and successfully proceed to the true embellishment of this important town, and to the reputation and profit of the professional members of this society; and I feel sure that, apart from every other consideration, the love of art, for its own sake, will stimulate every gentleman whom I now address in his efforts so to act his part as to leave associations of beauty and refined taste connected with every architectural monument of which the chronicler of future times shall record his name as the author.

THE DESTRUCTION OF CHURCH ORNAMENTS IN LINCOLNSHIRE AT THE REFORMATION.

An interesting paper on this subject appears in the last published collection of reports and papers of the architectural societies of York, Lincoln, Northampton, Bedford, Worcester, and Leicester. It is by Mr. Thomas North, honorary secretary of the Leicestershire Architectural and Archæological Society, and was read at a meeting of that society.

Few persons acquainted, even in a slight degree, with the variety and nature of the necessary

furniture of an English parish church in pre-Reformation times, and with the many fittings vessels, and vestments essential to the performance of the public worship, or the occasional offices of the church, and the celebration of the sacraments, can fail to be surprised that so few of those articles are now in existence to attest their former abundance and general use. Although the great mass of the people discarded, in the sixteenth century, many of the doctrines and customs of the Romish Church, there were undoubtedly not a few who still openly or secretly adhered to them, and who would as a consequence, it might fairly be presumed, have preserved as precious relics of their long used, and still loved, services and liturgy some of their least expensive and more easily concealed requisites. To describe in detail the means adopted for their almost entire destruction would be a long, an interesting, but at the same time, to some extent, an unnecessary labour. When Henry VIII. began his war with the Papacy, the religious houses – first the smaller, then the greater—were dissolved. The rich plate belonging to these was swept into the King's exchequer and converted into money. The then cathedral church of this diocese—Lincoln—contributed in one year (1540) 2,620 oz of gold, 4 285oz. of silver, besides precious stones almost innumerable. Upon the accession of Edward VI., injunctions were issued regarding the fittings and furniture of our churches. These were followed by orders in council and commissions, the purports of which were, amongst other things, to command the removal of almost all the appliances of the Romish ritual and ceremonies from the churches, and to cause their destruction or their conversion into money. That the course then followed would lead to abuses and extravagances was to be expected. Edward VI. found it necessary to issue letters relative to the alienation and destruction of church goods by persons applying the proceeds to their own use. He appointed commissioners in each county to prevent the indiscriminate sale of vestments, plate, jewels, ornaments, bells from the steeples, and lead from the roofs of the churches. Although during the brief reign of Edward VI. the churches were to a great extent stripped of their rich plate and of the requisites for the altars and of the other essentials of the mediæval services and ceremonies, still there does not appear to have been that systematic destruction of them which took place in the reign of Elizabeth, for upon the accession of Mary very many of those articles were forthcoming, having either fallen into friendly hands or been preserved for various reasons by the persons who purchased them from the churchwardens in the previous reign. Not that the churches regained a tithe of their ancient splendour during the reign of Mary—the besom of destruction had been too busy for that—but we must look to a somewhat later date for that almost entire destruction of all the accessories of mediæval worship. To such an extent did the spirit of destructiveness hold sway during Elizabeth's reign that she was compelled to take a similar step to that taken by her brother, Edward VI., in order to prevent, if possible, needful reformation from becoming licentious disorder. In a letter addressed by her to the commissioners for causes ecclesiastical, in 1560, she complains that

> In sundry churches and chappels where divine service, as prayers, preaching, and ministration of the Sacraments be used, there is such negligence and lacke of convenient reverence used towardes the comelye keeping and order of the said churches, and especially of the upper parte called the chauncels, that it breedeth no small offence and slander to see and consider on the one part the curiositie and costs bestowed by all sortes of men upon their private houses, and the other part the unclean or negligent order or spare keeping of the house of prayer by permitting open decaies and ruines of coverinages, walls and wyndowes, and by appointing unmeet and unseemly tables, with fowle cloths for the communion of the Sacraments, and generally leavynge the place of prayers desolate of all cleanlyness and of meet ornaments for such a place, whereby it might be known a place provided for divine service.

How far the Queen by her own example, and by this and other means, succeeded in stemming the reaction that set in against the undue exaltation of the externals of religion as carried out in the English Church in pre-Reformation times, and in checking the spirit of greed, and the want of reverence for holy places and holy things, which then were forming so strange and strong a contrast to the liberality and simple—though it may be said, blind—faith of earlier times, is well known. We in this generation have felt fully that the reaction just referred to was too strong to be checked to any great extent at the time it set in. In a vast number of dilapidated and decaying churches we see its result; in an almost entire neglect of the use of "meet ornaments," we trace its effects. In 1566 returns were made by the churchwardens of each parish to certain Royal Commissioners of such articles of church furniture as had been in their possession in the reign of Queen Mary, but which were then considered to be superstitious or unnecessary. Fortunately many of these returns, made from the neighbouring county of Lincoln, are still in existence, and have been recently transcribed and edited by Mr. Edward Peacock, F.S.A. A glance at these will show the procedure adopted throughout the country. The altar used in the church before the Reformation was a stone one, and therefore not movable. The altar stone was the large unbroken slab placed upon its top—unbroken, to symbolise the unity of the church. This altar stone generally bore upon it five crosses marked previous to its consecration; and within a cavity in it, or under it, were usually placed some relics of a saint or a consecrated wafer. When the doctrine of transubstantiation was rejected by the Church of England the stone altars were ordered to be destroyed, and movable tables of wood to be used in the liturgy. How thoroughly this was done is shown by the very few stone altars now standing in their original places, and also by the very few altar stones which have been discovered appropriated to other uses. The returns from Lincolnshire are very explicit in the information given as to the fate of the altar stone in each church; its destruction was clearly considered a matter of importance by the commissioners. One very common way of disposing of the altar stone was, after breaking or defacing it, to use it as paving stone in the church. A careful examination of the floor of a church will sometimes now reward the ecclesiologist with the discovery of a piece or pieces of the altar stone from the high or side altars, easily recognisable by the consecration crosses. Thus, the churchwardens of Ashby-juxta-Sleaford say—"Itm or altar-stones—brokne and pavid in or churche, Aō quitō Elizabethe." Very many others tell the same tale. The people of Bardney, however, say—"Itm ij alter stones—laid downe in the churche vnbroken." It would be well if these documents recorded no worse desecration than this of the altar stone. We find men putting it to what they termed "prophane vse," such as "bridges paving," like the churchwardens of Burkstone, of Bitchfield, and of Croxby; the repairing of private houses, as was the case at Braceby; the mending of the highways, like the men of Bradley. Again, we find altar stones put to more "prophane vse" still. Thus the churchwardens of Crosby say—"ij alter Stones:—One Mr. Sheffied haith made a sinck of it in his kitchine. . . ." Those of Horbling confess that their altar stones were broken and made into "troughes," others were made into a "cistern bottom," "set in a fire herthe," "lieth at Mr. Harr'gtns fier back." It is pleasant to turn from these descriptions to the note made by the people of Aslackby: "Itm one alter stone—laid upon a grave and so continueweth . . . .;" and more still to that entered by the churchwarden of Owmby—"Itm one alter stone sold to Willm Thixton, and he caused yt to be laide on his grave when he departed." This custom of using the altar stones for grave stones is thus curiously illustrated in the return from the parish of Haither:—"Itm as for alter stones we had none in quene maries tyme, but certaine grave stonnes weh wee were faine to take up of or church flower, and when the alters were taken downe we paved theim againe."

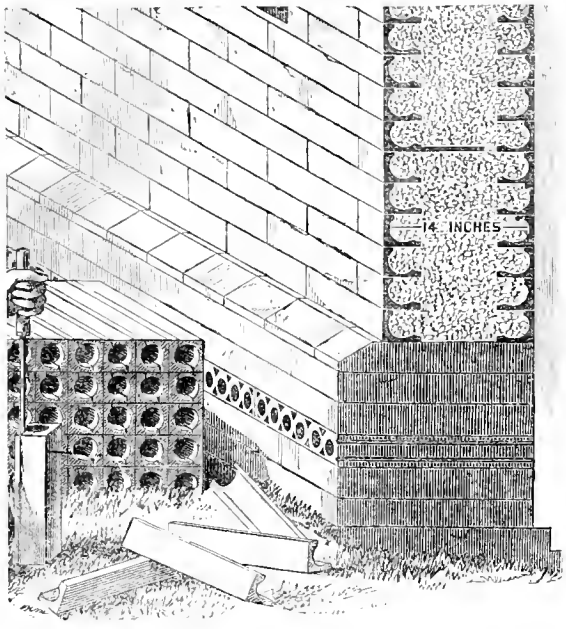
METROPOLITAN GAS SUPPLY.

THE amusing absurdities resulting from the neglect of the salutary maxim that "the cobbler should not go beyond his last" are very numerous, yet the proposition to supply London with gas manufactured at Newcastle probably surpasses most of them. The proposition is one which has been from time to time brought forward almost from the first introduction of gas-lighting at the beginning of the century; but as it invariably emanates from those who have no practical acquaintance with the subject, and will not trouble themselves to ascertain the experience of others, their suggestions might be permitted to pass unnoticed but for the unfortunate circumstance that those are permitted to legislate who are utterly ignorant of the subject to which their legislation is directed. It is stated that the Metropolitan Board of Works has again had the question of the removal of gas manufactories "from the populous districts of the metropolis" brought under its consideration; and in connection with that circumstance some would be *sarcastic* laments that the proposition for a remedy "to the present dangerous and preposterous system of making gas in the most crowded parts of the richest city in the world" should be limited to removing the factories "into the country," and conveying the product by a few miles of piping to the consumer. This authority writes that he really cannot understand why our gas should not be made at the mouths of the coalpits that supply the material, which, by a costly and tedious process, is at present brought to London by rail or sea, the freight being not less probably than 10s per ton between the pits and the factories, all of which the consumer pays, besides being injured in health and endangered in person by means of the manufacture taking place in that which is the worst possible spot in the world for the purpose. The cost of laying down gas mains between London and (say) Newcastle would not be greater than the maintenance for a short period of the fleet of colliers which bears the crude material to London, where wages, living, and land are more costly than anywhere else.

In the celebrated Doulton trial recently concluded at Brussels, one of the interested parties explained that his reason for making certain demands, which the court considered exorbitant seeing that the services rendered were of an imaginary character, was that "he always understood that the English were very eccentric in money matters," and certainly the recognition of such schemes as that referred to would be admissible as conclusive evidence of the accuracy of that opinion. The whole of the arguments adduced are entirely fallacious, and display the utmost disregard for every essential fact. The make of gas in the metropolis at present far exceeds eight million thousands of cubic feet per annum, which in round numbers requires the consumption of 1,000,000 tons of coal, and involves an outlay by the gas manufacturers, for raw material, wear and tear of plant, and labour, of about £1,000,000. But of the eight million thousands manufactured not more than six million thousands reach the consumer, one-fourth of all the gas made being lost by condensation, leakage, &c., so that the companies (taking the average at 4s per thousand) only receive £1,200,000 for their annual make. Now if the loss in delivering even from the works to the consumer in the same district is 25 per cent. it can readily be imagined that the attempt to convey gas to London from even the nearest coalfield would be attended with so serious a loss that we might be deprived of our gas supply altogether unless we consented to a considerable advance in the price of gas. But the actual loss of gas is not the sole objection to its manufacture at a distance from the place of consumption; the mere cost of overcoming the friction resulting from the passage of the gas through the pipes, so as to maintain the requisite pressure at the burners, would vastly exceed the cost of conveying the coal the same distance; the cost of keeping the extra pipes in repair would exceed the total cost of making the gas, even in London; and a comparatively trifling injury to the provincial main might leave the city in darkness for an inconvenient period. With regard to the injury to health asserted to be attendant upon the manufacture of gas, it certainly has not been proved, nor is it likely to be proved, that the odour which escapes from gasworks is in any degree unwholesome, although it is, beyond question, very unpleasant.—*Mining Journal.*

Mr. Howell, surveyor to the parish of St. James, Westminster, in a report made to the vestry of that parish, states that serious stoppages happen in the sewers by the accumulation of ballast and gravel. The causes of this accumulation are several; one being that at the time the sewers were built openings or "eyes," covered with pieces of wood, were left for the purpose of connecting the house drains at some future period, which it was expected would have lasted long enough or until the connection was made. It turned out subsequently, however, that it was too much trouble to find these "eyes," or from some cause they were not found, the drains were otherwise constructed, and in course of time the pieces of wood decaying, the rats commenced operations upon them, and the sand and heavy soil beginning to run into the sewer, soon caused an obstruction.

CONCRETE BUILDING WITH A BRICK FACE.



CONCRETE BUILDING WITH A BRICK FACE.

AT the present time, when so much attention is being bestowed on concrete and the erection of all descriptions of buildings with this material, it will interest our readers to notice the system now in operation for stabling and boundary wall in course of erection on Richmond Hill, close to St. Matthias Church, which we now illustrate.

The walls are principally 14in., faced on either side with an elbow-shaped block, made of the best clay. The one side of the block is bedded into the wall, the other forms the face, and at the same time the trench for the concrete.

In this system the work is equal to the best face brick, and is said to combine all the advantages of concrete in cheapness of construction, strength, dryness of wall, &c.

Alfred Smith, Esq., 19, Buckingham-street, Strand, is the architect. Mr. Pither, of Sunninghill, Berks, is the contractor.

The Broomhall Tile and Brick Company (limited), of Cox's Wharf, Blackfriars, S.E., hold the patent for and supply the blocks.

PULPITS.

ALTHOUGH the word "Pulpitum" was employed by the ancients to signify merely "a place raised where the speaker stands," the word with us has come to be applied almost exclusively to an enclosed or semi-enclosed place for a preacher, in contradistinction to the platform or raised open space or stage which were the earliest speaking places.

For the traditional idea of our pulpits we are of course indebted to the early Gothic artists, and, as their ideas were founded on the natural requirements of the Catholic religion, the pulpit, we find, is far less emphasized than the altar or reredos. With them the pulpit was conventionally simple, being only an accessory in the picture of which the magoificent high altar is the chief figure. This being the focus* to which all eyes were turned during the great ceremony of their church, it was of a surety *the* point to render emphatic; hence the accessory pulpit is simple, quiet, and retiring, while on the altar is lavished all the richness their wealth would give and all the beauty their fancy could conceive.

In Protestant churches, however, the altar does not play such a conspicuous part, and though in the ceremonial of the English Church it still holds a place (rather misty and undefined), which increases in importance as we approach ritualism and dwindles to next to nothing in Low Church, in most other Protestant churches the altar is entirely abolished, as in the Church of Scotland and most of the English Dissenting chapels. In these the position occupied in former times by the altar now holds the pulpit, and it has become in its turn the focus for both eyes and ears. In many churches or chapels of this class the pulpit is worked up till it loses its true purpose and becomes, in some sort, a shrine to contain the congregational divinity, who sits enthroned like Olympian Jove or Alexander Selkirk, "monarch of all he surveys." This arrangement of having the pulpit at the centre of the end wall tends to destroy all ecclesiastical feeling, and to substitute that of the lecture hall, and to foster the idolatrous feeling with which a clever preacher is regarded, and contributes in a great degree to that noble emulation in the diviner sex which displays itself in the working of slippers, braces, and other necessaries of civilised life for presentation to the congregational idol.

The position of the pulpit in Episcopal churches has something graceful and poetic in it. The pulpit is neither in the centre nor at the end of the building, and the chancel space beyond encourages us to look physically and mentally beyond both pulpit and preacher—physically to, perchance,

> . . . the high embowed roof
> With antique pillars massy proof,
> And storied windows richly dight,
> Casting a dim religious light.

and mentally, to the more glorious pictures which are ideal, evanescent, and of the invisible, which is beyond all.

It is the fashion for pulpits to be smaller nowadays than in the days of our grandfathers. Action, which Demosthenes regarded as the chief part of oratory, is now considered *infra dig.* by modern curates, and it is only in very unfashionable churches, or in the pages of Dean Ramsay, that we get glimpses of those good old stout defenders of the faith who pommelled the cushions and battered the book-board in their metaphorical fights with the Prince of Darkness. Pulpit action, like the legitimate drama, being thus under a cloud, pulpits are worn very much smaller now in consequence.

Before concluding this, which has grown a longer article than I intended, it is worth while observing that, although the Catholic *Gothic* pulpit is small and unassuming, directly it is Classicized or Italianized, it becomes magnificent and triumphal. Note those, for instance, of the chief Italian and Spanish churches. Note, too, that a good lesson may be learnt from pulpits of other styles besides Gothic and Classic. For spirit and delicacy of treatment, I have seen nothing better than the Arabian or Mahometan pulpit lately acquired by the Kensington Museum. In the sketch in this week's number, the pulpit is shown nearer the centre of the chancel than its true position in order to give more of the design.

J. M. S.

* "Focus" means literally fire hearth or altar.

NORTHUMBERLAND HOUSE.

AT the last meeting of the St. James's Vestry, Mr. Webber moved "That a memorial be addressed to the Metropolitan Board of Works, urging on them the propriety of taking such steps as may be necessary to secure a West End approach to the Thames Embankment by the purchase of Northumberland House, and strongly urging that no other route than a direct line to the Embankment through the site of Northumberland House will answer for the extensive and increasing traffic from west to east." It was far from his (Mr. Webber's) wish that fair compensation should not be given for the property in question, but he should like it to be based on its present value, and not upon what it will be worth when some millions of the public money have been expended on the neighbourhood. When the question was before Parliament all sorts of means were adopted to defeat the bill. A sensational notice had been circulated among members of Parliament to the following effect:—"Certain division, 4 o'clock, Monday, February 26. Your attendance is earnestly requested in the House of Commons at 4 o'clock to-day to save Northumberland House, which is menaced with destruction by the Thames Embankment (North) Approaches Bill. Mr. Beresford Hope will move the rejection of that Bill, and you are earnestly requested to support him." Mr. Webber hoped that such practices would not be tolerated in a Reformed Parliament. Mr. Downes seconded the motion, and Mr. Bidgood, in support, said that it was only fair to state that it was not during the present Duke's time that the division took place. The Metropolitan Board required backing-up in their action. No other entrance to the Embankment from the West End would be worth a rush. The motion was carried with but one dissentient.

DUMBARTON BURGH HALL AND ACADEMY.

THIS building was completed about two years ago from the designs of Messrs. Wm. Leiper and R. G. Melvin, architects, Glasgow. There are two halls. The large or main hall is placed immediately behind the front building, and access from the main street is provided by a spacious corridor entering from the open porch which forms the base of the tower. A smaller hall is situated on the first floor of the front building. Waiting rooms and large class-rooms occupy the rest of the building. The whole of the external walls are of freestone. The open porch at base of tower has a groined roof. Depth of shadow in the window openings is gained by the glass being recessed the full thickness of the walls. The whole cost was about £7,500. Mr. Thomas Rissett acted as clerk of works.

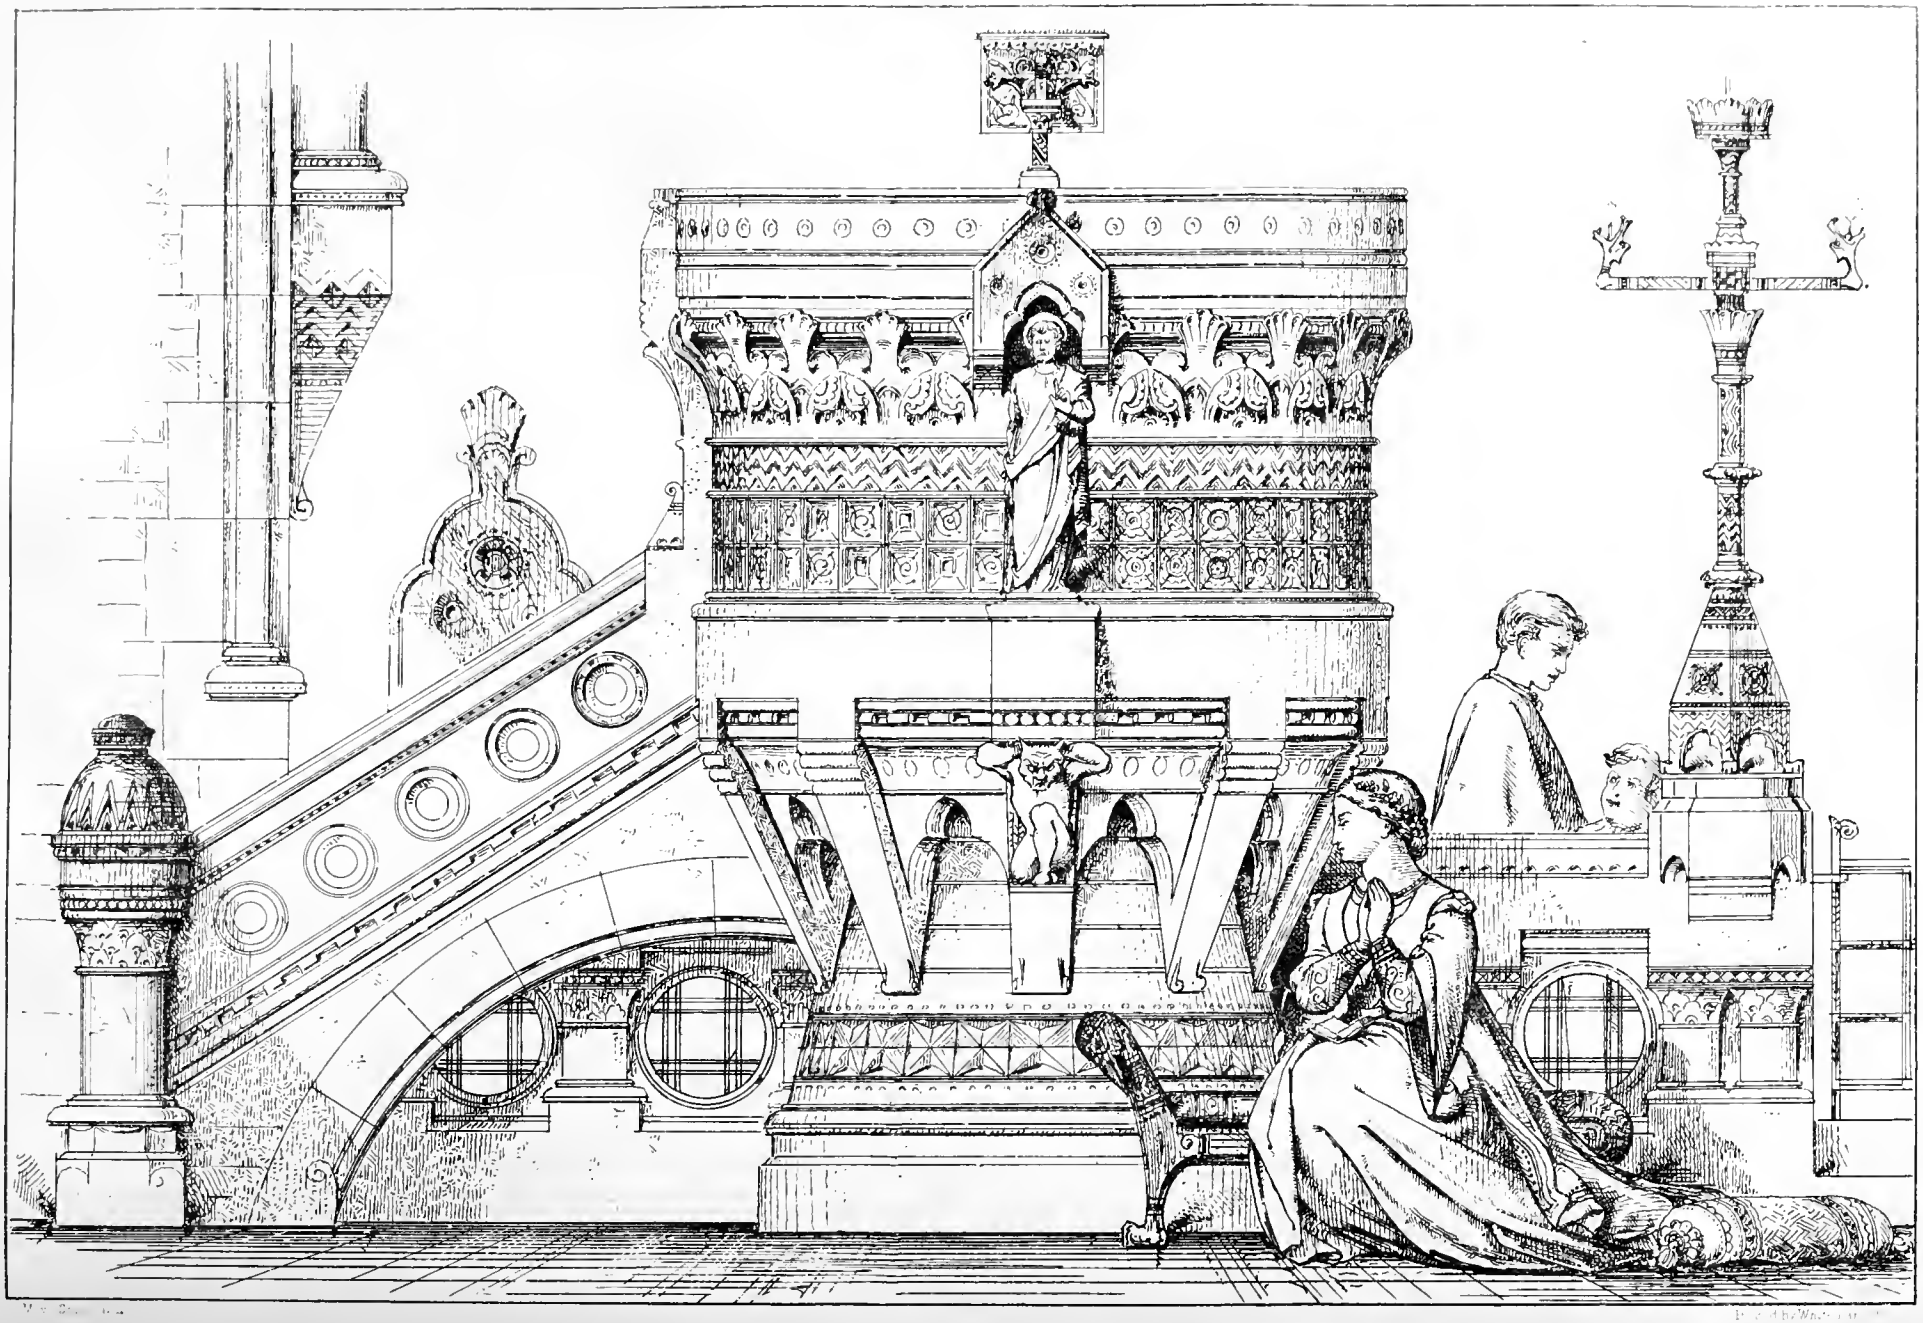
THE NEW HOTEL DIEU OF PARIS.

THIS building is progressing rapidly, it being the Emperor's wish that this house of the poor should be completed before the new Opera House. Such is the care bestowed on the brilliant and profuse ornamentation of this latter edifice, and such the expense which it entails, that it is said it will not be completed before some seven years hence. Meanwhile (says *L'Union Medicale*) the whole of the area which the new Hotel Dieu is to occupy is covered over, and measures not less than 22,000 square metres. Three distinct blocks of buildings already begin to take form and shape. When finished these blocks will constitute three pavilions, the principal fronts of which will face Nôtre Dame. The first or front block will be appropriated to the administrative department, the reception and waiting rooms, and lodgings for officials. On either side of the courtyard will be a large amphitheatre for clinical lectures. The second block will be a vast longitudinal edifice, which will serve to connect three pavilions situated on the right for male patients, and three on the left for female patients. Large open gardens, planted with trees and shrubs, and surrounded by galleries, will separate the different pavilions. The third part of the building forms a large courtyard facing the Quai Napoléon, in which will be comprised the chapel, the dead-house, &c. The kitchens, the bleachery, and the various stores occupy the basement. The hospital is to contain no less than 700 or 800 beds.

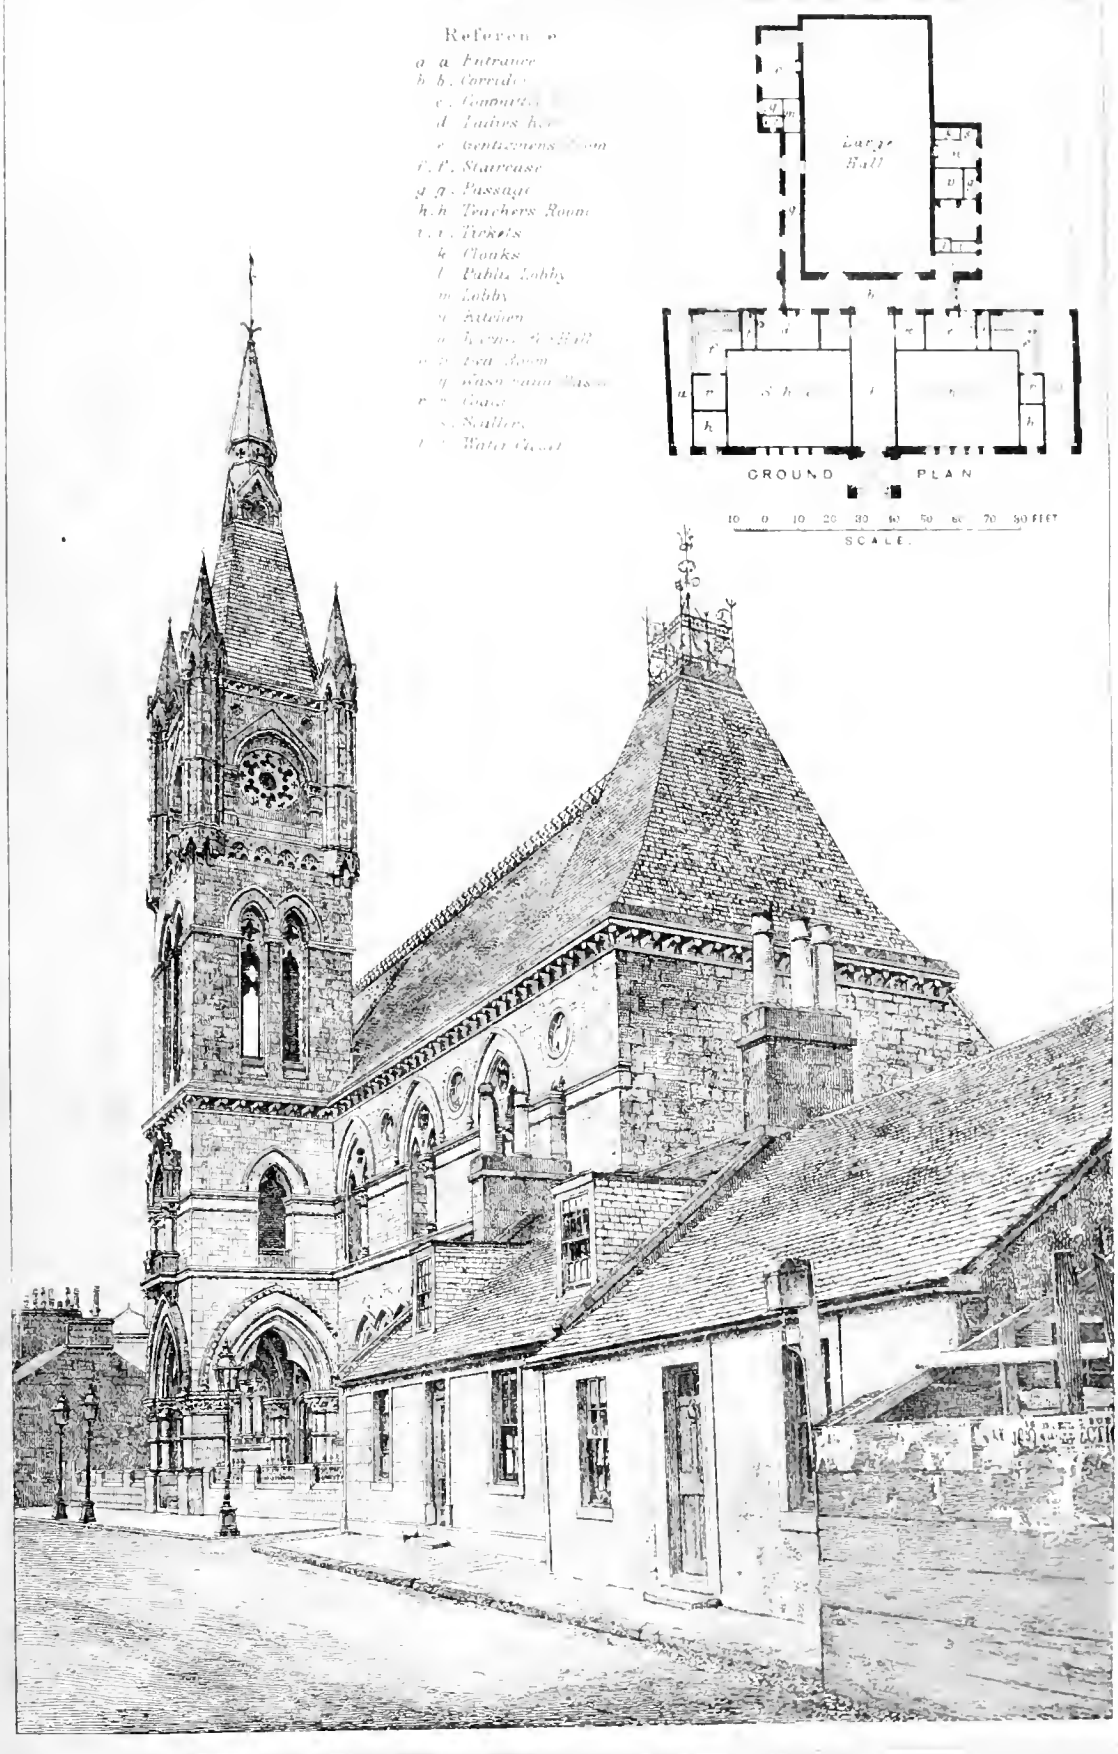
ADAPTABILITY OF SLATE.

A HOUSE has recently been built at Brownsville, Maine, U.S., which is not only shingled, but is clap-boarded with slate. It is a slate *edifice*, fireproof and indestructible. The slates are put on to the boarding of the walls with only paper between. They are in the form of segments of a circle, overlapping each other, and have a very ornamental effect. The natural colour of the slate is pleasing to the eye, and no paint is needed. If it were the slate would furnish it, for when ground it makes an excellent paint, which has been used on a barn with good effect. The whole establishment is elegant in appearance, and shows what can be done with native materials. The front steps are of beautiful slabs of slate; the sinks, mantels, and shelves are of slate; the woodwork is brown ash, a native wood, which makes a handsome finish. In short, this is a real State-of-Maine house, and shows the wealth of her resources. The slate costs little, if any, more than clap-boards. When this material can be economically brought to us slate houses will become fashionable.

Mr. H. Clutton has been requested to submit plans for the Roman Catholic cathedral in Westminster.



PULPIT, &c.—Designed by J. Moyr Smith.



New Burgh Academy & Hall, Dumbarton.

W. LEIPER, ARCHT.

ST. PAUL'S, PAST AND PRESENT.

NEVER before in the history of art were there so many educational influences at work as there are now in the present nineteenth century days, all having for their ultimate object the improvement, as it is called, and the progress of art, and the building and decoration of better and nobler buildings. Never before were there so many societies for the sole purpose of accomplishing all this, but, in spite of these gigantic efforts, the art produced and the buildings erected utterly fail to equal, much less surpass, those which have preceded them, and which certainly had never any such advantages and furtherances. When St. Paul's Cathedral was designed by Sir Christopher Wren, and built under his immediate and *daily* superintendence, there was no architects' institute in existence, no antiquarian society, and surely no class of learned lecturers to point out to the architect what he had to do, and what was most fashionable. Wren laboured under not a few disadvantages, and when we carefully examine his work it is surprising to see how well he did it, and how fine and true his natural aptitude for it was. Assuredly it well made up for all these deficiencies; nay, sometimes we cannot help thinking that ignorance itself is a gain instead of a loss, for the whole faculties of the mind are thus concentrated on a single object and style of art. A few thoughts, therefore, on this great work of Wren's may prove of some interest, and cannot be otherwise than instructive if carefully considered with the building itself in view all the while, for its present and probable future condition well deserve attentive study. We may begin by affirming that, where it can be done, it is most desirable to build *solidly* and with walling of sufficient thickness, and that, when possible, it is a capital thing to build the *inside* of a structure as solidly and with as good and true materials as the *outside*. No living architect, I presume, exists who would not congratulate himself on the fortunate chance of being able to line the whole of the interior of a church, or even room, with solid stone instead of plain plaster. Marble may be an impossibility, but stone, if you can get it, all will agree to. The builder of Westminster got it somehow or other, and so did Wren, luckily for us, or we should never in these days have known what was meant by a stone interior. In these days we are too poverty-struck for such solid luxuries. Any modern man, therefore, who has been fortunate enough to reach this height of expensiveness will at least go one step further and agree with the dictum, that having got a good and fair stone facing inside the building, whatever it may be, it is, and must therefore be, most desirable to show its reality, *i.e.*, to let the world see that *it is stone*, and not plaster on brick, or common oil colour on plaster. It may therefore not a little surprise some who see this for the first time to be made aware of the fact—for fact it is—that the whole of the real and solid stone interior of St. Paul's Cathedral has been covered up and painted over four times in common oil colour, as near to the colour of *new* stone as may be, and that consequently all the advantage that is to be got from the lucky fact of the inside of this building being *real* is totally lost. It is all just as if the building were constructed of common brickwork, plastered over and painted in the ordinary way. I am sorry to be obliged to say that this "ornamental" feat was the work of the late Professor Cockerell, the then architect custode of this great cathedral. It is quite a little bit of architectural history, and belongs to St. Paul's, and ought to be recorded here if nowhere else, for we feel sure that Dean Milman has said nothing about it in his forthcoming "Memorials of St. Paul's." I have two special reasons for these few lines about it—first, because I personally tried hard to persuade Mr. Cockerell *not* to do it, and almost offended him thereby, and next, which is the important point to be considered, it just one-half destroys the building as a "sound-chest;" and then again it will show what the word restoration really in these days does mean.

Before the interior of this fine building was thus painted in common oil colour and the reader is earnestly desired to go and look at it and not to take anything that is here said on credit merely), the whole of the interior was, of course, visible Portland stone, not of its natural colour, as fresh from the quarry, but as coloured by weather influences and time. What was this colour in the building? Westminster *is* coloured, and so *was* St. Paul's; anyone, therefore, may see for himself what it is by a little careful looking at the inside of the Abbey; and no one, I think, will contend that the interior of it would be *improved* by its being painted stone colour like a common shop front or a smart street doorway. St. Paul's had some of this natural colour in it, far richer and deeper than any that painter could put on it; but when I presumed to ask Professor Cockerell "Why he had painted the whole of the *plinth* all round the interior of the Cathedral new stone colour?" he replied, "Because, sir, it was dirty." So, as the reader may see, is the plinth all round and the bases everywhere of the columns of Westminster Abbey; and so even now is the *floor* of St. Paul's, and so is the woodwork of the stalls; why not, therefore, paint all of them, and thus hide the dirt everywhere. There is now in reality, and it is worth noting, no difference whatever between the inside of St. Paul's Cathedral and the very cheapest of cheap chapels, where every brick almost has been counted and the commonest and cheapest of materials used in its construction. May it not, therefore, be said that a very sad mistake was made when this wretched paint was made to hide the building? and may it not be laid down as an architectural axiom that where there is natural colour it should be left *to show itself* fairly and truly? But this is not all. There would seem to be, in addition to the *purity*—I can find no other word—of *natural* colour, as seen in all materials that are not artificial, a certain transparency and depth, which, as it were, remove the object *from* the eye, and soften the impression which it makes. It is difficult to make this clear to anyone who has not already observed it, but never was it so visible to memory and eyesight as in the past and deplorable present state of the *dome* of St. Paul's. I say it deliberately when I affirm that the dome, before the drum of it was painted, as seen from the floor of the cathedral, looked just half as large again as it does at this moment now that it has been painted in common oil stone colour to match the plinth and the walls; and for the simple reason that the depth and *transparency* are gone. It is dismal work this fault-finding, but I do not see how any greater injury can be done to the prospects of art and architecture than this of the central and chief building of the metropolis of a country being so misused and destroyed artistically, and made the subject of mere vain and foolish experimenting. It would take some time to endeavour to explain what is meant by colour in a building, as no one ever seems to be able to perceive that even *black* when diversified is *colour*. Why the outside of this building of St. Paul's is coloured with a far deeper tone and intensity of hue than any one of the portraits of Velasquez, where, as Ruskin has so well noticed, the "blacks" are more resplendent than most other painters' "crimsons;" and there is more real colour in a dull background of Rembrandt than in all the reds, and yellows, and blues, of our Academy Exhibition put together. If the outside walls of St. Paul's, now thought to be dirty, could be transferred and turned inwards, and so roofed in, and the black and grey of them to be in the interior instead of exterior, then would the interior of St. Paul's be the most wonderfully coloured building in existence, for the simple reason that nature and art had accomplished the work. Who will, therefore, say that St. Paul's Cathedral does not stand in need of "restoration" by cleaning off the oil paint from the whole of the inside of it so industriously put on it by the learned Professor of Architecture at the Royal Academy!

It is comforting to see that one or two *panels* here and there have been lately cleared of their coating of paint by the somewhat unfortunate and destructive process of planing or smoothing or *polishing* them, thus destroying the tool marks of the workman, and of course the character of the mouldings round the plain wall facing. Surely nothing more is or can be needed but the mere and simple removal of the thick coat of paint. St. Paul's, I say again, is a sort of experimental warehouse, and one is a little curious to know what is to be stored up in it, and where the "crane" is to be to lift it all into position. One is fairly appalled at the sight of the *iron* girders! In our little quarrel in the building itself I said to Mr. Cockerell, after all other arguments, colour included, had failed, "You will destroy the *sound* of the place." He replied, "Nonsense! how!" I do not know whether the singular fact has been noticed of how resonant, to use the familiar word, an unpainted wainscoted room when empty of furniture is, and how finely any musical instrument (as a violin) always sounds in it, and how, again, it is found to lose much of this resonant clearness when it comes to be thickly covered with oil paint. I once had the opportunity of observing this fact. It would take time to try to explain the cause of it, but here, and for our present purpose, the bare fact is enough; and it is the same with stone as with woods, the coating of paint will be found to deaden, almost to destroy, the clearness of the sound reflexions and air tremblings. Mr. Cockerell did not deny this; but, as we see, it did not prevent him from doing all the mischief he has done, and which it must be for his successors to remedy. St. Paul's is not a good place for sermon hearing or for prayer reading, but it is in this country altogether unrivalled and unequalled as a place wherein these may be emphasized, and the dulness of dull reading made endurable and sometimes intelligible.

C. B. A.

PROPOSED NEW FISH MARKET AT FARRINGDON-ROAD.

THE Smithfield Market Appropriation Committee, to whose efforts may be ascribed the erection of the new meat and poultry market on the site now occupied, entertaining strong convictions of the appropriateness of the land lying between the new market and Farringdon-road for the purposes of a fish market, have availed themselves of the professional services of Mr. Lewis H. Isaacs, architect, of Verulam buildings, Gray's Inn, to demonstrate how that object could best be obtained, and have published a plan, of which we have received a copy, showing the situation of the proposed market and a view of the intended structure as seen from the Farringdon-road. The ground proposed to be utilised is a parallelogram, bounded on the north by the new road leading to the Charter-house, on the south by an intended new street in continuation of Long-lane, on the east by the new street now formed at the end of the meat market, and on the west by Farringdon road. The total area of the land is 198,400 square feet, of which 126,000ft. would be occupied by the building, and the remainder would be devoted to the courtyard next the Farringdon-road and to the formation of the new street on the south. The design of the proposed market is similar in almost all respects to that of the new meat and poultry market; it would be in fact a continuation or repetition of the building. The cost is estimated at £150,000, to which must of course be added the value of the land.

We understand that the Port and Harbour Commissioners of Hartlepool have adopted the plans of Messrs. Harrison and Jaffrey for the improvement of the harbour.

SCHOOLS OF ART.

ON Thursday evening, November 5, the annual distribution of prizes awarded by the Science and Art Department to the students of the Hull School of Art took place at the Public Rooms. The Mayor, in distributing the prizes, remarked at some length on the good prospects of the school and the assiduity displayed by the students. Mr. Rowney (secretary) read the master's report, which showed a very satisfactory state of things, and that at the commencement of the year the Department of Science and Art issued a memorandum offering bonuses ranging from £50 to £10 to those masters of Schools of Art in which the results as tested by the examinations of the department should be most satisfactory. Mr Chandler, the master, obtained a bonus of £10. Votes of thanks were proposed to the Mayor and Mr. W Chandler, which those gentlemen suitably acknowledged and the meeting terminated.

On Monday evening a new Building Evelyn School for Technical Education was inaugurated at Bradford.

An exhibition of paintings and drawings illustrative of the government scheme of art instruction by Schools of Art, was held in the County Hall, Lewes, on Wednesday last, and in the evening a lecture, explanatory of the subject, was given by Mr. Fisher, the master of the Lewes School of Art. Drawings and paintings, executed by students in various schools of art, were arranged on the walls in a classified order. The explanations of the specimens and of the value of the study involved in producing them was listened to with much attention, and at the close of the lecture, after a vote of thanks had been accorded to the lecturer and to the chairman, the majority of the audience remained to re-inspect the drawings, &c., in the light of the information they had just obtained. In addition to the set of students' works, a number of paintings and drawings by Mr. Fisher were also exhibited, and, as testifying to the careful study by which he has qualified himself to instruct in the various branches of art, they formed an interesting part of the exhibition.

ARCHÆOLOGY.

INTERESTING discoveries have been made by the opening of a barrow on Tredinney-hill, six miles west of Penzance. The barrow is nearly a complete circle, with a diameter of 38ft., enclosed by an outer circle of large granite slabs set on edge. A trench having been sunk in the middle of the mound to a depth of about 18in., the explorers came to a large pile of granite rocks heaped together promiscuously. The course of one of these, which sloped in an easterly direction at a distance of 7ft., was followed, and led to a flat stone, 3ft. by 2ft. On raising this stone the rim of an urn was seen, filled with fine dark earth, and further exploration proved that this was of the ancient Celtic kist vaens, and one which has turned out to be unique in the district. Instead of being formed in the usual way of four stones set on edge, it was constructed of two stones to each wall, the upper one slightly overlapping the other in such a manner that the urn, which was placed mouth downwards, was tightly wedged in. The only other kist of this description ever discovered in Cornwall was at Gwithian, in 1741. The kist discovered is about 1ft. square, and just large enough to contain the urn, which is 1ft. high and 9in. in diameter at the mouth. It is ornamented round the upper part by three bands of rude irregular indentations, which extend over four knobs or handles protruding from the sides. The style of pottery is rude, and the vessel is not so well baked as most of the urns which have been found in the neighbourhood.

WATER SUPPLY AND SANITARY MATTERS.

A SECOND enormous reservoir for the supply of Paris with water is now in course of completion at Montrouge; this is to receive the waters of the River Vanne, which will be brought to the capital by means of an aqueduct which crosses the valley of the Bièvre, and is constructed upon the arches of the Aqueduct of Arcueil, originally built to bring the water from Rungis for the gardens and fountains of the Luxembourg. In the time of Henri Quatre, the Minister Sully caused researches to be made to discover whence the Romans obtained water for the Palais des Thermes, the remains of which are annexed to the museum of the Hotel Cluny, but it was not until the year 1613 that the works were commenced for bringing water from Rungis to Paris; the aqueduct was designed by Jacques Desbrosses—executed by Jean Coing, at a cost of £18,400, and terminated in 1864; it is on the old arches of this aqueduct that those of the new one are being constructed.

Building Intelligence.

CHURCHES AND CHAPELS.

On Thursday, November 5, a new Congregational Chapel was opened at Hull. The style is Gothic, and the cost £8,000, including £4,500 for land. The plan consists of transept and nave—the transept 72ft. in length, and the nave 50ft. wide. Accommodation is provided for 1,000 persons, two galleries in the transept and one in the nave holding 300. Mr. Kitching is the architect, and Messrs. Hutchinson, of Hull, the contractors.

Yesterday week the old church at Ewyas Harold, Herefordshire, was reopened after restoration by the Bishop of the diocese. A portion of the tower has been rebuilt, and the whitewashed ceilings have been removed, discovering a well constructed oak framed roof, which has been renovated. An archway has been opened out between the nave and tower, affording additional accommodation, and a new vestry and porch erected. C. C. Haddon, Esq., of Hereford, was the architect, and Messrs. E. and J. Giles, of Ewyas Harold, the contractors.

After thorough restoration by Mr. G. E. Street, Lillingstone Dayrell Church, Bucks, was reopened by the Bishop of Oxford on Sunday, November 8. The church is a very interesting little fabric. It is for the most part Early English, but the chancel arch is Saxon and the arch of the tower Norman; there are windows of later date, and a fine stone roofed porch of the fifteenth century. The north aisle, which was demolished some 200 years ago for sordid reasons, has been rebuilt. The entire cost of the work has been defrayed by Mr. A. J. Robarts, of Lillingstone House.

BUILDINGS.

New warehouses for Messrs. Wright and Co., provision merchants, have been erected at North Shields. The style is Byzantine, worked out in red and white bricks, the front broken by corbelled pillars and strings, terminated by a cornice. Mr. Martin Greener, of Sunderland and South Shields, is the architect. The completion of the building was celebrated on Wednesday week by a dinner to the workmen.

On Saturday afternoon, Mr. C. M. Palmer, of Jarrow, presented new schools to the parish of Easington, Yorkshire. The schools are the design of Mr. Richards, and are in the Gothic style. They will accommodate 110 children at a cost of about £1,000. There are separate entrances for boys and girls, and there is a large class-room and every convenience.

The foundation stone of a new Roman Catholic College for the diocese of Waterford was laid on Tuesday week at Upper Grange, on the outskirts of the city. On the true ancient collegiate plan, the college will embrace a large central court, surrounded by cloisters, class rooms, library, refectory, kitchen, offices, and numerous commodious apartments for professors and students. In the centre of the courtyard will be a church. The buildings will have a front elevation of 170ft. The estimated cost is £12,000. Mr. George Goldie is the architect, and Mr. M'Mullen, of Cork, the contractor.

TO CORRESPONDENTS.

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

RECEIVED.—T. W. C.—T. C. H.—Midland Railway Co.—E. S. (Hull.)—M. and Co.—H. G., see B. C. B. Society.—G. and C.—R. C.—A. L. B.—C. S. Co.—Smithfield Market Committee.—J. I. M.—R. A.

J. T. BELL, Moorfield.—Your letter throws no new light on the unlucky accident at Twickenham. As to the latter part it is an attack only on an advertisement which appeared in the BUILDING NEWS. We can therefore only insert it as such. The controversy now going on between the two patentees must be excluded from our columns.

E. COOK.—We should be glad to act as you suggest, but it is now a rarity to meet with good works of the description you admire. You probably noticed Mr. Thompson's building at Glasgow, which we illustrated two or three weeks since.

C. W., Cork.—It rests with our readers to enhance the value of "Intercommunication." We do all we can and are glad to know that it is appreciated.

Q. E. F.—Simply by forwarding illustrations of works from which we make our selection.

FERRARUM.—In our description last week of the new Court House, at Falkirk, we stated that Mr. Ford was the architect. We since have learned that Messrs. Browne and Wardrop, of Edinburgh, were the architects, Mr. Ford being the clerk of works.

Correspondence.

ARCHITECTURAL ASSOCIATION.

To the Editor of the BUILDING NEWS.

SIR,—I trust you will allow me to correct an error in reference to the supplemental report of the committee of the Society of Arts on Education.

It seems that in my address I attributed to Mr. Burges the part which was taken by Mr. Seddon, the indefatigable secretary of the Royal Institute of British Architects, who was nominated by the council of the Institute to represent them in the sub-committee, and who was instrumental in bringing forward the important suggestion alluded to.—I am, &c.,

WILLIAM WHITE, President A. A.

Wimpole-street, November 9.

SOUTH KENSINGTON SKETCHING CLUB

SIR,—It appears that my letter of the 30th ult. is considered rather severe, as I have been assailed by a reply in your last number from "M. T. L.," in which he has used most unbecoming epithets and insinuations, all of which I am happy to say I can afford to despise. Undoubtedly, it is gratifying to many to see how courageously he has endeavoured to defend the course taken in the late proceedings, but being an outsider, and not enjoying the pecuniary advantages of that institution to which so many owe their "little fame," I feel at liberty to protest against what I consider prejudicial to my interest. I am only an evening student anxious to receive whatever instruction can be obtained in the short time allotted, and to have my drawings exhibited was my object in sending them there, to have their defects pointed out was my highest aim, and by special order of both master and secretary I affixed my name to each in order that they might be returned to me. As to "spiteful insinuations," of which I am accused, I emphatically deny them, and that stale and vulgar cant of the dog and the manger is a most absurd and inapropos remark. As I am above falsehood I ignore that expression, but return him the empty compliment of his own language two-fold, by telling him he is guilty of a grievous error in stating that I am the only one dissatisfied with the club management. Believe me my sentiments are felt by many who will not or care not to express them.—I am, &c., JUSTICE.

SMOKEPROOF ARCHITECTURE.

SIR,—In an article in your last impression entitled "Smokeproof Architecture," there are several points relating to terra cotta on which I trust you will permit me to make some observations. I am the more induced to address you because I see in your report of Mr. Tite's very able speech at the inaugural meeting of the Royal Institute of British Architects, that that gentleman made some very serious objections to terra cotta as a building material.

There is, as you remark, a growing tendency to revive the use of terra cotta, and it is important, therefore, that the various advantages which it possesses should be impartially contrasted with the objections to its employment. Mr. Tite, I am obliged to confess, is far from doing justice to terra cotta, and I am thus led to believe that he has been very unfortunate either in the choice of his material or in the manufacturer whom he has employed. I am not acquainted with the statue at Brighton, which he instances as an example of the want of durability of terra cotta, but I must point out two facts with reference to it. One is that terra cotta is from its nature a very unfit material for large public statues, and also on account of the difficulty and danger of firing pieces of any considerable size entire; and the other is that the constant exposure even of the most durable substances to the salt and moisture of the sea air is found fatal to them. Mr. Tite states that the arm and leg of the statue have been broken off. Surely marble would have been equally liable to mutilation from wanton mischief.

The fact mentioned by Mr. Tite that the terra cotta work of St. Pancras has failed in a good many instances is quite new to me; indeed, I have always regarded that church as a monument of the lasting character of the material under notice, when exposed to the atmosphere of London. Mr. Tite is, however, perhaps not aware that the terra cotta work of St. Pancras is the joint production of two firms—Messrs. Coade and the Brothers Rossi. The latter gentlemen were, I believe, the sculptors who modelled the whole of the enrichment, and who, on quarrelling with Messrs. Coade, built some kilns of their own and completed the remainder of the work, which consisted of the enormous caryatides and the superstructure which they support. I am unable to perceive that, in any instance, there has been a total failure of a block, but in two or three cases an evidently imperfectly fired portion of the enrichment has lost its sharpness and scaled away to the same extent as the Portland stone with which the building is ashlared. These blocks should manifestly have been rejected in the first instance by the architect. I have never myself been able to ascend very close to the most exposed parts of the terra cotta work, which may have failed as Mr. Tite describes, but those portions to which I have been able to get near enough to examine them carefully are all

that can be desired in point of preservation. Now, St. Pancras Church was built in 1821.

The remark in your article that terra cotta varies greatly in quality is most true, and badly fired and imperfectly made terra cottas are worse than useless for building purposes; to this class must belong the enrichments of the new Metropolitan Extension Railway stations, as their failure in so short a period can be due to no other cause than to faultiness in manufacture. Even bricks, which are inferior terra cottas, last for scores of years in London without showing signs of decay.

The danger from frost to which you allude might surely be omitted, as every substance is open to this objection—moisture is just as likely to attack the joints of granite as of terra-cotta. I may note here that terra cotta should never be left hollow; it is made so for facility of drying and firing and is sent hollow from the manufacturer, but this fact may be reckoned as one of the great advantages which it possesses over stone, as here you have the means in brick buildings of bonding and incorporatiog the dressiugs and enrichments in the most perfect manuer with the walls and other work.

Permit me totally to disagree with you with reference to the play of colour in terra cotta. There is not the slightest necessity for any very important variation in the tints, as blocks which are too light in hue may be fired again and have their tone thereby deepened to any extent. The dirty white colour you speak of is almost invariably a sign of an inferior article and should be rejected by the architect: thoroughly well-burnt terra cotta should never be paler than a straw colour, and tints varying from this to a deep amber colour, sometimes warming into a rich flesh colour, are what I should exact from a manufacturer. I have always felt the interchange of tints in a large front to be of the *utmost value* in point of effect, and in no other material can this interchange be obtained with the same facility and certainty of success as in terra cotta. The fact of the article under our notice being a burnt clay points it out especially, as you observe, as a dressing for brick buildings, and the danger you allude to of infinite repetition is more a fancied than a real evil.

A matter of the utmost importance with reference to the use of terra cotta is that it must always be treated and described as a substance entirely different from stone. The attempt to make terra cotta like stone, or to employ terra cotta for stone dressings, does always, and can only, result in failure. Terra cotta architecture must be studied as a speciality, and the size and arrangement of the blocks, the projection of enrichments and mouldings, and the colour must be peculiar to terra cotta. Any comparison of terra cotta with stonework, therefore, is a mistake, and to lay down as a rule that good masonry must always be superior to it is, I am convinced, equivalent to saying that painting must always be superior to sculpture.

In selecting polished marble and granite for the enrichments of the London of the future, you overlook, I fear, two facts—one is that you cannot build wholly in polished materials, even were they procurable in sufficient quantities, and such a building, even if executed, would most likely be a failure; the second is, that such materials would almost entirely preclude the employment of decorative features, as these are incapable of polish, and from the dark colour of most of these substances they would be ill-suited for the display of ornamental features. I must admit, however, that you indicate what we really want, that is, a substance with an imperishable vitreous surface, into which no moisture can soak, and to which no soot can cling. This we are now about to obtain in glazed or enamelled terra cotta—the revival of the old Della Robbia ware, with a harder and more durable ground; and from the samples of this material which I have examined, I confidently look forward to the time when terra cotta, glazed and unglazed, will make the buildiugs of smoky London not only beautiful, but at the same time imperishable.—I am, &c., GILBERT R. REDGRAVE.

CONCRETE HOUSES.

SIR,—I do not mean to take up your space with a personal altercation with the patentee, whose name I should not have agaiu brought forward but for his contradiction of my facts. Let me set myself right with your readers in a few last lines. I can *prove* that my walls were at least 18ft. high when Mr. Tall saw them, and gave beer-money to the men. If he came after September 3 they were proportionately higher. The plan he sent to you is far from correct, and many of his statements wrong as to detail, and he shows considerable igoorance in asserting that "the cement was purchased because it was 1d. a bushel cheaper," when, in fact, it cost me more than the previous lot.

If the foundations were insufficient, and if the cement was "some of the worst (he) ever saw," I can but say that the man he recommended to me planned the one, and *advised* and purchased the other. As to my having said that Mr. Tall was "responsible for" or "superintended" the work, I defy him to extract such meaning from my letter; and with regard to the quality of the "rubble" blocks (the size of which I admit) I spoke of, I send you a piece, broken off a larger block, by the head only of a pick, that you may judge for yourself.—I am, &c.,

GEO. LARDEN, D.C.L.

P.S.—May I ask how Mr. Goodwin (whose letter is a pleasant contrast) could possibly have seen a house and "looked over it" *after* the date of my letter on the 31st, which was totally cleared away off the ground on the 24th? However, it is not of any consequence.

[With regard to Mr. Goodwin's letter, we, by leaving out a long and unnecessary intervening paragraph rendered the commencement of his letter somewhat ambiguous. There can be no doubt that he saw the building. We have allowed this correspondence to appear while it was at all connected with the merits or demerits of concrete as a building material, but it has now become a merely personal dispute between the patentee and Dr. Larden, and each having had the opportunity of contradicting the other's statement, we can insert no more letters on the subject. We have before us several other letters giving similar accounts of the building to those given by Mr. Newton and Mr. Goodwin, but cannot possibly afford space for their insertion.—ED. B. N.]

Intercommunication.

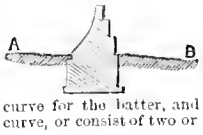
QUESTIONS.

[1118.]—SHAPE OF CHIMNEYS.—Having to build a small chimney-shaft, about 45ft. high, I should wish to know whether it would be better to build it square on plan or round. I should be greatly obliged to any correspondent who would inform me on the matter, and also give me a general idea about what the dimensions ought to be at bottom and at top.—BUILDER.

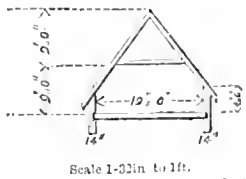
[1119.]—MEASUREMENT OF BRICKWORK.—I have had to measure up some work in walls and buildings to check the measurements of another surveyor, but I find that he gives the results of his in cube yards of brickwork. I give mine, as is the usual custom, in statute rods, and I am at a loss to know how to prove whether they tally or not. Can any reader kindly assist me?—E. B.

[1120.]—FALLING BODIES.—Is there any rule for determining the rate at which bodies will fall? and will a heavy body fall faster than a lighter one? Does a body in falling continue to increase the rate at which it falls? and if so, what is the law, if there is any, which it obeys?—STUDENT.

[1121.]—BATTER OF WALLS.—In building retaining walls is there any necessity for continuing the batter below the ground line? or should the foundations be carried down plumb, as shown in the annexed cut? I should be glad if any subscriber would let me know the best way of describing the curve for the batter, and whether it should be a uniform curve, or consist of two or three with different radii.—J. P.



[1122.]—ROOF CONSTRUCTION.—Is the collar in the sketch in a state of tension or compression, and are purlins necessary; if so, what scantlings, and where should they be placed? and how are the collars joined at the intersection of two roofs situate at right angles with each other?—BEGINNER.



Scale 1-32in. to 1ft.

[1123.]—WAR DEPARTMENT CLERK OF WORKS.—Will some of your correspondents be good enough to inform me how to obtain an appointment as clerk of works to War Department, as I am anxious to get one? also what are the salaries given? and oblige—A CONSTANT SUBSCRIBER.

[1124.]—ORNAMENTATION OF IRON.—I have read with great interest the article which appeared in the BUILDING NEWS of October 30, on "The Ornamentation of Iron," and should be very glad to be more fully informed on this subject. Can any of your readers inform me where I could get fuller particulars as to mixing the paint; also whether the same process is applicable to brass, and if not, what alterations must be made in the chemicals used? By inserting this in your next number you will much oblige—G. E. R.

[1125.]—BUILDING SURVEYORS' CHARGES.—I shall feel obliged if one of your numerous readers will kindly inform me what percentage (on the rent per annum when let for building) should I charge for the following:—Surveying land and laying out the same, arranging with adjoining landowners, introducing a respectable builder, conducting all correspondence, and furnishing various persons with copies of the plan?—NOVICE.

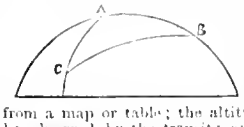
[1126.]—CIRCULAR GAS TANK.—I would be thankful to you or any of your readers for information on the undermentioned subject, viz., a circular gas tank, 14ft. in diameter and 14ft. high inside, finished measurement. I excavated 9ft. deep, which was gravel, and then formed gravel layer and good puddle mixed to a depth of 6in. I drove an iron bar through this layer, and water came up. I stopped the hole made by the bar with puddle, then built the circular stone wall which forms the tank with sound stone and good lime and good sharp sand a thickness of 20in. This wall I raised higher than the surface, and backed it with the excavated gravel, so as to strengthen the superstructure; coated the inside of wall with Portland cement and sharp sand 1in. thick; laid 6in. of puddle in the bottom of the tank, well incorporated; on the puddle I laid a course of flags, and a coat of Portland cement and coarse sharp sand on the flags. In a month after this I filled the tank with water to within 16in. of the top. I could not fill it higher. The next morning it fell 4ft lower, and in three days the water was all out, except 21in. in the bottom. I pumped that out, and could not see any defect in the cement except two small bits in the angle of the bottom. I re-did these in cement; and on the original floor laid another 12in. of good puddle and flags down on the original floor. I have filled it a second time with water, and it has lowered 9ft. in three days.—F. N.

[1127.]—GUINEAS.—I have in my possession an old guinea, dated 1788. The inscription on one side is "Georgius III. Dei Gratia," on the other "M. B. F. et H. Rex. F. D. B. et L. D. S. R. I. A. T. et E." I can make out the first part easily enough, but I do not understand all the abbreviations. If any of your correspondents could enlighten me on the subject I should feel much obliged.—ROBERT WILLIAM.

REPLIES.

[1083.]—WATER SUPPLY.—The area of the gathering ground must first be carefully ascertained from a good map. Should there be no map, a survey must be made, in order to obtain its measurement. This survey need not embrace details, but should be sufficient to enable the engineer to calculate the superficial extent of the land included. The area having been determined, the average rainfall in the district may be ascertained either by actual experiment, or better and more speedily by meteorological statistics. With these two data, and making a due allowance for local evaporation, the quantity of water that may be expected and fairly relied upon may be easily calculated.—CALX.

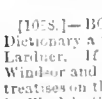
[1084.]—REGULATING TIMEPIECES.—"Verax" may proceed as follows, but he must bear in mind that it will take one or two trials, perhaps more, before he will be able to accomplish what is rather a delicate operation. It is a question of spherical trigonometry. In the figure, let the sun be supposed to be at C, then what is required is the hour angle, which is the angle A B C. The data required are the latitude of the place of observation, which can be got from a map or table; the altitude of the sun, which can be observed by the transit; and the declination of the sun for the day and time of observation. This last is given in the "Nautical Almanac." By the laws of the solution of spherical triangles, when three sides are given, any of the angles can be calculated. Consequently, if we could find the values of the sides A C, C B, A B, we could determine the value of the hour angle A B C. But A B is the complement of the latitude, A C the complement of the observed altitude, and B C the polar distance or complement of the declination. Putting S for the half sum of the three sides, we have the following formula for finding A B C:—



$$\text{Log. tan. } \frac{A\,B\,C}{2} = \tfrac{1}{2}\left(10 - \log.\sin S + 10 - \log.\sin (S - A\,C) + \log.\sin (S - B\,C) + \log.\sin (S - A\,B)\right)$$

Having found the value of A, we can turn it into time by knowing that 15° = one hour. Suppose the value of A to be 46° 20' 20", then we have the proportion—15° : 46° 20' 20" :: 1 : X, and X = 3h. 5m. 21s. Subtracting this from 12, and adding 3m. 15s. as the equation of time, we find the true time to be 8h. 57m. 54s. If we suppose the clock to indicate 8h. 50m., then it is 7m. 54s. behind time.—NAUTA.

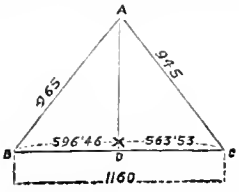
[1087.]—SUPPORT FOR FLOORING.—Instead of using brick arches I should advise your correspondent to strengthen his floor by simply bolting on a second set of beams side by side (see figure) with the existing ones. Together they would be amply strong for the purpose, and would not exercise any effect upon the side walls.—A. S. X.



[1088.]—BOOKS.—"A Student" will find Dr. Ure's Dictionary a very good one; also another by Orr and Dr. Larduer. If he were to write to the well-known colourists, Windsor and Newton, they would send him a list of their treatises on the subject he wants. There is a capital work in Weale's Series, called "Painting, or a Grammar of Colouring," by George Field.—X. B.

[1089.]—COLOURING DRAWINGS.—If the paper be properly strained upon a board it will not crease when a wash of colour is laid on. The reason that creases often occur in drawing paper that has been coloured is that the colour has not been allowed time to dry before the paper is worked upon. Whenever creases do occur, they may be altogether removed by well damping the paper upon the other side, and, if necessary, pressing it well besides with some heavy books, or anything that may be handy.—S. T. W.

[1039.]—AREA OF TRIANGLES.—All the solutions to V. P.'s problem of the triangle in your impression of the 30th ult., are arrived at by taking the square root of the continued product of half the sum of the three sides, and the respective differences of the three sides and the same half sum. I beg to offer the following solution by finding the segments of the base:—Call one of the sides, say the longer one, B C = 1160ft., base; then say, as the base (B C) is to the sum of the two other sides (B A + A C), so is the difference of these sides (B A — A C) to the difference of the segments of the base (B D — D C). 1160 : 1910 : : 20 : 32.931 = difference of segments of base. Half the difference of these segments added to half their sum will give the greater, and half the difference taken from half their sum will give the less. Thus—



580	580
16.4655	16.4655
596.4655 = greater B D.	563.5345 = less D C.

The perpendicular A D is found by using the well-known 47th proposition of the First Book of Euclid.

$$A D^2 = A B^2 - B D^2.$$

A B = 965	Log. B D 596.4655 = 2.7755854
965	2
4825	Log. 355771.25 = 5.5511708
5790	
8685	

$A B^2 = 931225$
$B D^2 = 355771.25$

Log. 575453.75 = 5.7600104 ÷ 2 = 2.8800052 = Log. A D. The area is found by taking half the product of the base and perpendicular height, thus, by logarithms:—

Log. Base B C 1160 =	3.0644580
Log. Perpendicular height A D =	2.8800052
Log. 879960.6 =	5.9444632

439,980.3 = area in feet = 48,886.7 square yards.—MARTIN B.

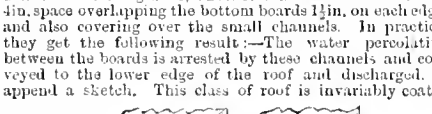
[1099.]—In reply to "V. P." I never use any angular instrument. If the triangle be laid down from a large scale, the perpendicular may be measured and the area found by the usual rule. Or, from half the sum of the three sides subtract each side severally; multiply the half sum and the three remainders continually together, and the square root of the last product will be the area of the triangle. Thus: 1165 + 965 + 945 ÷ 2 = 1535 the half sum, 1535 — 1160 = 375. 1535 — 965 = 570. 1535 — 945 = 590. Then we have √(1535 × 375 × 570 × 590) = 33478630434 square feet, the area of the triangle.—E. H.

[1049.] I beg to observe that I do not understand "Robey Carpenter's" mode of finding the area of a triangle (printed in the BUILDING NEWS of November 6) by making use of the number 15 301. If "Robey Carpenter" will kindly send in a solution having given that the angle at A = 74° 47' 6.56", B A = 965, and A C = 945 (the same as in the original triangle given by "V. P." in the BUILDING NEWS of October 30), he will oblige—RAYMOND F.

[1104.]—APPRAISER'S LICENCE.—If "C. H. King" prices or values work that he measures, I should recommend him to take out a licence; if he does not, and his valuations should at any time be disputed in a court of law, the judge would not receive his evidence to prove his own valuations, which might cause a loss to his client.—S. JACKSON.

[1114.]—MACHINE WORK.—In reply to your correspondent "One of the Olden Times," in the BUILDING NEWS of November 6, we beg to offer to him, through your medium, our machine-made mouldings, which we know to be first class, but if not approved can be returned to us at our expense. We are sure they will give perfect satisfaction.—CRAVEN BROTHERS and Co., Darnall, near Sheffield.

[1116.]—WATERPROOF WOODSHED.—Buildings of a cheap and temporary character require covering with less costly material than slate, tile, or metal. In this case wood naturally presents itself. It is cheap, light, and easily wrought, but being subject to a greater amount of expansion and contraction under the influence of our changeable climate than is the case with other and more costly coverings, it presents difficulties that we are at a loss to overcome. One of our most ordinary modes of covering is that of "weather boarding," with 11in. or 9in. boards, ¾in. or ⅞in. in thickness, the lower edge of each board being nailed upon the upper edge of the board below. There are several objections to this principle. Firstly—If they are narrow boards, the upper face—from the lower edge of the board being placed upon the upper edge of the previous board—is so nearly horizontal on its upper face that the rain naturally beats under the boards. This may in some measure be overcome by having the roof of steep pitch; but here again comes the question of cost. Secondly—If they are broad, thin boards, we are bound to secure them on both edges. This prevents the natural expansion and contraction of the wood; the consequence is, in extreme hot or dry weather, the boards will split down the centre. Another mode of covering is with upright boards running from the eave to the ridge, the joints covered with boards or strips. This plan is preferable to the former, inasmuch as the water is more readily discharged from the roof. One of the causes of this kind of roof being defective is the distance of the side trees or purlins; the lower boards are not well supported, and the water percolates under the overlapping covering. If this is remedied, we are bound by the laws of construction to secure the boards on their outer edges. Here, again, we find the boards split down their centres in hot or dry weather. We have instances of wood being cut into the form of slates, and used in like manner, with great success. This plan can only be recommended in connection with saw mills producing a quantity of waste material that could be cheaply converted into a covering of this character. On the whole, our methods of constructing wood roofs are defective. We naturally call in the aid of roofing felt, painted canvas, tar intermixed with lime or sand, &c., to enable us to make them waterproof. In England we are blessed with an abundance of building materials, the best of which we can apply to the most suitable purposes. This is not the case in other countries, especially in the north of Europe, where one or two kinds of constructive materials wholly prevail. In Sweden and Norway wood is essentially the material for building, with the exception of a few panes of glass and a few bricks for the chimneys. The houses—away from the large cities, where its use is prohibited—are entirely constructed of wood. The question of constructing waterproof wood roofs has had their most serious consideration. Having travelled over a portion of that country, and being deeply interested in all matters pertaining to the building trade, I hope a few details under the heading of wood roofs may be interesting, if not instructive, to your correspondent. The most ordinary—and certainly the cheapest—mode of constructing waterproof wood roofs is that of "shingles." These are mere shavings cut from round whitewood poles about two feet in length; they are of various widths, graduating from the first shaving from the round pole to the broad shingles cut from the centre of the wood. As an article of commerce, they are packed in wood frames, 2ft. square, and as the shingles are 2ft. long, a bundle is consequently 2ft. square all ways. In this form they are dipped in creosote oil for 5in. or 6in. from one end, and are sold for 8s ore (9½d.) per bundle. In covering a roof, they are placed several thicknesses together at the eave, and as they are distributed over the roof they are allowed a lap of 19in., showing a face to the weather of about 5in. It naturally follows, as every 5in. of the shingle is overlapped by an additional one, there is no part of the roof where the shingles are less than five in thickness. They are nailed upon laths in rows the length of the roof, in the same manner as slates, but instead of abutting to one another at the edges they are overlapped. For instance, a row of shingle is fixed, commencing from the left-hand end of the roof; as each shingle is fixed it overlaps the preceding one about 1in. along its edge. This is repeated to the other end of the roof. The next row is commenced from the opposite end, and is lapped in a contrary direction. This principle effectually precludes the beating rains from driving in at the joints. The sun curls up the edges, and splits the lower end of the shingles in the form of a comb, but still the roof is sound and watertight. For better class houses, these roofs are again lathed upon the top, and covered with pantiles; in this case the shingles are used to exclude the frost in winter, whereas with an ordinary tile roof they would be uninhabitable. Another mode of covering, and one perhaps more in unison with the views of your correspondent, is that of upright boards. These boards are 7in. wide and 1¼in. in thickness, placed about 4in. apart. The upper face of each board has a channel ¾in. wide and ¾in. deep, running from end to end along each edge of the board. This being done, another board is nailed over the 4in. space overlapping the bottom boards 1¾in. on each edge, and also covering over the small channels. In practice, they get the following result:—The water percolating between the boards is arrested by these channels and conveyed to the lower edge of the roof and discharged. I append a sketch. This class of roof is invariably coated



over with wood or Stockholm tar intermixed with red ochre. This material gives a nationality to all their rural erections.—W. S., Nottingham.

BUILDING AND LAND SOCIETIES.

ON Wednesday evening, the 4th inst., the first appropriation meeting of the City Central Mutual Benefit Building Society was held at the Broad street Ward Charity Schools, No. 59, London wall, when upwards of 600 shares were allotted. The society is a terminable one, limited to 1,200 shares of £150 each, and has for its object the assisting and encouraging of saving habits in its members by the admittance of small regular payments, which are to be safely invested, and of rendering practicable a system of small mortgages, with a view to enable each of the members to obtain an advance of £300 for the purchase of leasehold or freehold property. The money is advanced for 12½ years, and is repayable at £24 per annum, without any interest or premium for balloted shares, the appropriation being by two ballots and one sale alternately. The subscription, at the rate of 2s 6d a share, is payable on the first and third Wednesday in each month.

WAGES MOVEMENT.

A CROWDED and influential meeting of delegates from most of the metropolitan trade societies was held at the Bell Inn, Old Bailey, on Saturday evening last, to consider what steps should be taken to forward the adoption of arbitration in trade disputes. Mr. Allen (Amalgamated Engineers) presided. Mr. Dunning, bookbinder, moved:—"That this meeting of trades societies' representatives approves of the principle of arbitration, in the belief that it is the best method of settling disputes between employers and employed, and recommends that trade committees, in their various localities, seek to bring about meetings of masters and men, with the view of establishing boards of conciliation and arbitration; and this meeting feels deeply indebted to Mr. Mundella for the successful efforts he has made to establish such boards." Mr. W. Hammett seconded the resolution, and Mr. Odger (secretary, London Trades' Council), in support, said that the trades of London had adopted the principles of arbitration some years ago, but the question now was how best they could carry it into operation. Some weeks since, having business with the new Lord Mayor, Mr. Alderman J. C. Lawrence, he mentioned the subject to the worthy alderman, who said that he should be happy, at the commencement of the new year, to attend a conference of masters and men for the mutual consideration of the subject. Mr. Mundella had also promised to attend the conference, which, no doubt, would be the most important held for many years in this country. After a few remarks from Mr. Lloyd Jones, the resolution was carried unanimously, and the proceedings terminated.

The operative carpenters and joiners of Bristol have given notice to the masters that on and after May 1 next they wish to leave work on Saturday at 12 o'clock, and to receive an advance of one halfpenny per hour on the present rate of wages.

STATUES, MEMORIALS, ETC.

THE ceremony of unveiling the relief monument of the late Admiral Sir Charles Napier, which fills one of the niches in St. Paul's Cathedral, near the north entrance, took place on Friday last. The expense of this monument was defrayed by a few friends and companions-in-arms of the late admiral. It is of white marble; in the centre is the head, in bold relief, surrounded by a wreath of laurel and oak, and upon two flags are the names of most of his battles; in the background is the ship Wellington, gunboats, and a fortress blown up; beneath is the simple inscription, "Charles Napier, M.P., Admiral, Count St. Vincent, born 1786, died 1860." The work was designed and executed by George G. Adams, sculptor, who has now five monuments in the Cathedral, two being colossal statues of the Admiral's cousins, the Generals Sir Charles and Sir William Napier.

LEGAL INTELLIGENCE.

IMPORTANT CASE.—THE QUEEN *v.* THE METROPOLITAN BOARD OF WORKS.—In the Court of Queen's Bench on Wednesday last, this case (which was an appeal by the board against a poor rate levied on their sewers in the parish of Greenwich) was argued, and the question raised was whether the sewers are rateable. The claim was made on the ground that the sewers were used for purposes of profit, inasmuch as the sewage was disposed of for manure. The technical form which the rate assumed was this:—It was upon freehold ground belonging to the board within the parish occupied by the length of sewers within the parish; and, further, the board were rated in respect of the area of land occupied within the parish by the buildings erected for the pumping engines, &c; the gross estimated rental was altogether put at £9,520, and the rateable value at £5,114, upon which the poor rate at 1s. 1d. in the pound came to about £300. The board appealed upon the grounds—1, that the property was not in its nature rateable; 2, that the board had no occupation of the property in respect of which they were rateable; 3, that they had no beneficial occupation; 4, that the board did not inhabit the parish; 5, that the board did not nor did any person derive any benefit from the works; 6, because the parish and not the board derived benefit from the works; 7, that the board had no interest in the soil; 8, that the board occupied only under their Act of Parliament, and for the purpose of the Act. Of course, if the present claim was sustainable, the sewers would be rateable in all the other parishes through which they passed; and the magnitude of the question may appear from the aggregate amount of the sums levied and expended by the board. And by a Parliamentary return of April 10, 1866, it appeared that the board had raised £7,500,000, and had repaid £800,000, leaving unpaid £2,750,000, on which interest had been paid to the amount of £502,000. And, on the other hand, it appeared that the total expenditure had been £3,584,846. An idea of the magnitude of the works may also be obtained from a printed report of the proceedings of the board presented to Parliament under the Act, in July, 1865. From these and other official documents it will be seen that there are 82 miles of sewers in London. The sewers were constructed under the 11th and 19th Victoria, cap. 120 (the Metropolitan Management Act); under sec. 135 of which the board were empowered to make such sewers as they might think necessary, and then by sec. 170 they are empowered to levy rates for the expenses incurred. And the 21st and 22nd Victoria, cap. 104, extended their powers. The sums levied by the rates were to be paid into the Bank of England. In the meantime, the board were empowered to raise money by loan, and the funds lodged in the bank were to be paid out by order of the Lords Commissioners of the Treasury until the money borrowed was paid off. Thus, it was contended that the Board of Works, in fact, never touched the money. It appeared that the board had entered into an arrangement to dispose of the sewage for manure, but that no profit had as yet been realised. The argument in support of the rate likened the sewers to the gaspipes or waterpipes of the gas and water companies or to canals. In the course of the argument, however, the Lord Chief Justice observed that there was a great difference in these cases. The mere fact that the board levied rates could not make the sewers rateable, or streets might as well be rated. Mr. Justice Lush observed that the Act of Parliament imposed upon the board the duty to erect the sewers and levy rates for the purpose. No other rates were leviable. After a long discussion judgment was deferred.

NOTICES OF BOOKS.

The Elements of Plane Geometry, for the Use of Schools and Colleges. By RICHARD P. WRIGHT, formerly teacher of geometrical drawing in Queenwood College, Hampshire. With a Preface by J. ARCHER HIRST, F.R.S., &c., Professor of Mathematics in University College, London. London: Longmans, Green, Reader, and Dyer. 1868.

THE author divides the contents of his volume into four books or sections, the first of which treats of the properties of lines and figures, formed by a

combination of any number of straight lines, including triangles, squares, parallelograms, and polygons, regular and irregular. To every chapter in the sections are attached a few miscellaneous examples for the instruction of the student and also inserted for the purpose of enabling him to exercise his own knowledge and ability in determining their solution. Practical examples of this kind are always valuable, as they serve to keep alive the interest of the beginner, and impart a real appearance to the study he is engaged in.

Book the second introduces us to the "circle," with its numerous accessories of arcs, chords, tangents, and segments. Full information is afforded to enable their various directions, magnitudes, and values to be determined. To thoroughly understand the different properties of the circle requires a little more mental exertion and perseverance than to acquire a similar knowledge respecting right lines and the figures formed by their combination. One does not "see" the solution so readily, or the different steps in the reasoning process so clearly in the former as in the latter instance; but by giving more attention to the subject, it will become clear, and well reward the labour bestowed upon it. In book third a still more difficult and intricate branch is taken up—namely, ratio and proportion. Commensurable and incommensurable magnitudes are clearly defined and illustrated, and the incommensurability of the diagonal and the side of a square well exemplified. Ratio and proportion are not confined to lines and numbers, as might be at first imagined, but all other figures, whether circular or rectilineal, can be accurately compared by these means. The areas of rectilineal figures, polygons, and circles are treated of in the last book or section, and a chapter upon the proportional areas of polygons concludes this well-written, well-digested volume. It is scarcely possible to endow geometry with any original or absolutely novel features, but the author has done more than we have witnessed in any of the many works on this subject to put it in a new dress, and has introduced some propositions which, so far as their particular application is concerned, have not appeared elsewhere. The diagrams are well cut, and the lettering bold and distinct. Bearing in mind that geometry constitutes the very first branch of rudimentary technical education, which must be soon extended to our artisans and working classes generally, plain practical textbooks are much wanted, especially those of a description which are tended rather to allure the beginner than scare him away—a result which not unfrequently follows the selection of an abstruse and difficult treatise for a new hand to commence with.

A Handy Book for the Calculation of Strains in Girders and similar structures, and their strength; consisting of formulæ and corresponding diagrams, with numerous details for practical application, &c. &c. By WILLIAM HUMBER, Assoc. Inst. C.E., Author of "A Practical Treatise on Cast and Wrought-iron Bridge Construction;" "A Record of the Progress of Modern Engineering," &c., &c. London: Lockwood and Co., 7, Stationers' Hall-court. 1868

WE entirely disagree with the author respecting his statement in the preface, that there are no works extant affording the requisite information upon the subject of strains. Mr. Stoney's work contains everything necessary for the calculation of the strains in the different types of iron construction.

To us it is simply impossible to treat the question, involving so much diversity and complexity, with any success in the manner proposed by the author. The volume becomes one mass of formulæ and figures, rendered doubly bewildering by the extraordinary manner in which the text is arranged, and by the miserably small type employed. If any description of book requires indispensably a bold, clear type, it is a volume of the character to which the present compilation aspires. Notwithstanding the assumption in the preface regarding strains, that "pocket-books have been compelled to leave its treatment incomplete," Mr. Humber would have done well to have imitated Mr. Molesworth in the general style and get-up of his valuable little work. The truth is, that the author, while affording a vast amount of information, has endeavoured to condense too much. It should be borne in mind that it will not answer to condense a subject for a beginner. He only becomes perplexed in his attempts to use a formula, the basis of which he does not understand. It is difficult to ascertain to what category "Strains in Girders" belongs. The author admits it is not a treatise. It is certainly not a pocket-book, and it can scarcely be called a hand book, in the strict sense of the term, since, in order to arrive at the solution of any particular example, it necessary to refer to three or four different parts of the volume. Many of the examples are more of a theoretical than a practical nature, and might be omitted with advantage. The diagrams, although small, are clear, and the plates equally good. The valuable portion of the book is the information afforded respecting the geometrical method of arriving at the strains of bridges and roofs.

A Treatise on Optics, on Light and Sight, theoretically and practically treated, with the application to Fine Art and Industrial Pursuits. By E NUGENT, C.E., Ex-principal of Commercial, Nautical, and Engineering College, New York. London: Virtue and Co., 26, Ivy-lane. New York: Virtue and Jorston.

IN spite of the support given by many distinguished mathematicians, opticians, and philosophers to what is termed the "theory of emission," the other more recently propounded doctrine known as "the wave or undulatory" theory of light is nearly universally recognised at present as the true cause of that remarkable phenomenon. Mr. Nugent, while mentioning the two theories, does not trouble himself about their relative merits or the claims which each may possess to be regarded as the correct explanation of the principle of light. Even in an optical treatise of a most scientific character, discussions upon these points are altogether superfluous. They generally only perplex instead of informing the reader, and nothing but actual experiment can ever advance our limited knowledge of the imponderable elements. The author has acted judiciously in abstaining from introducing into the instructive and interesting contents of his work any abstruse or extremely erudite matter, or in complicating the text with mathematical and algebraical formulæ. He has intended the volume to be of general not partial utility, and the manner in which the various branches of a subject so important have been treated fully justifies the opinion that his intention will be a very successful one. Starting with the two correlative principles of the refraction and reflexion of light, better known to the optician under the names of dioptrics and catoptrics, the two leading features may be briefly mentioned. A couple of simple rules suffice for establishing the relations existing between incident, refractive, and reflective rays of light. If a ray of light fall upon any transparent medium, it will be refracted, that is, bent or diverted from the line of its original direction by an amount depending upon the nature of the medium through which it passes. This amount is synonymous with the angle of refraction, which is always constant for the same medium. Thus, if the ray be incident upon a sheet of water, the angle of incident will always bear to the angle of refraction the proportion of 1·336 to 1. When the ray, instead of falling upon a transparent body, is incident upon an opaque one, it is reflected from the surface, and the universal rule prevails, liable to no exception, that the angle of incidence is equal to the angle of reflexion.

The chapters upon the aberration of light, its constitution and decomposition, are particularly deserving of attention, and the reader will find himself much interested in the experiments made by Sir Isaac Newton—the first to prove by direct experiment that all the seven prismatic colours, when again combined and made to fall upon the same spot, formed or recomposed white light. Sir David Brewster maintained that there are only three original spectrum or primary colours—namely, red, yellow, and blue. Mr Nugent mentions the other philosophers who coincide with Brewster, and sums up very fairly the relative arguments put forward by both parties, leaving the reader to form his own conclusion on the question. It is, nevertheless, generally considered that the discoverer of the law of gravitation was unconsciously led into error by the manner in which he conducted his experiments. Some instances are given of people who have suffered from colour blindness, or an incapability of accurately distinguishing some colours from others. One would not expect to find the name of the late Mr. Troughton, of the firm of Troughton and Simms, the eminent mathematical instrument makers, among those who were affected with this peculiar description of optical deficiency. But the fact is so; he was incapable of fully distinguishing colours, with the exception of blue and yellow. The author enters into an accurate description of the various examples of telescopes and the principles governing their construction. The stereoscope, kaleidoscope, cameras, and every sort of optical instrument, whether intended for the purposes of utility or amusement, are also described, and their leading features examined in detail. Taken in its entirety, we consider Mr. Nugent's volume to be one of the most readable that has come under our observation. He treats what is abstractedly a rather dry and difficult subject in an instructive and popular manner. It is just the sort of book that an artisan could read with advantage to himself, and really acquire a sound knowledge of optics, without being deterred by abstruse problems and mathematical investigations, which are so plentifully displayed in most treatises. The type is large and clear, and the cuts and diagrams distinct and well chosen for the illustration of the various subjects.

Our Office Table.

At the usual meeting of the Metropolitan Board of Works on Friday last, tenders were received for the execution of the work for the formation of the ornamental work of Finsbury Park. There were eleven tenders, but the one accepted was by Mr. James Clarke, for £7,130. A plan was also received and adopted for the improvement of Park-lane by the opening up of Hamilton-place as proposed by the bill promoted by the Board in 1865, and the taking of the two northernmost houses on the east side of Hamilton-place, and the solicitor was instructed to issue the necessary notices of the Board's intention to apply to Parliament for an act to enable them to carry out the improvement.

A meeting was held on Monday evening at Bradford to inaugurate the establishment of classes for the purpose of imparting technical and scientific knowledge to the operatives and apprentices connected with the building trades in Bradford and the neighbourhood. This movement was described by the chairman, Mr. A. Neill, as the first fruits of a Board of Arbitration which had been recently formed in connection with one branch of the building trades and of the combined efforts of men and masters to ensure the harmony and well-being of all connected with the trade.

An agitation has been commenced in Lambeth with the object of securing a portion of the extensive grounds at the rear of the archiepiscopal palace for purposes of public recreation. The new primate, whoever he may be, has here an opportunity of making a graceful concession to the inhabitants of a densely-populated district.

The multiplication and extension of metropolitan railways during the past few years, although conducive in the highest degree to the public convenience, have nevertheless not been without certain drawbacks. One of these is found in the miserable manner in which, in wet weather, rain-water leaks through the roadway of the numerous iron girder bridges on to the passengers and traffic below. This is, indeed, more than a drawback; it is an intolerable nuisance, and we are glad to see that the Lambeth Vestry is about to take steps for its abatement.

The Hydro-Carbon Light Company exhibited their new light in front of their offices at 18, Parliament-street, on Monday evening last, in honour of the birthday of the Prince of Wales. The value of the light was well manifested by its superiority over the adjacent gas lamps, the premises being distinguishable at a very considerable distance by the beauty and brilliancy of the light.

The meetings of the Institution of Civil Engineers will be resumed on Tuesday, the 17th inst., when a paper will be read "On Lighthouse Apparatus and Lanterns," by Mr. David M. Henderson, Assoc. Inst. C.E. In the interval that has elapsed since the close of the last session the premises in Great George-street have been entirely rebuilt, and the accommodation for members, both in the meeting room and in the libraries, has been more than doubled. The meeting-room will now seat comfortably about four hundred.

The King of Prussia has given to the inhabitants of Frankfort an annual donation of £3,200, the gift being assured for the next ten years.

The Dover Gaol Committee have had under consideration the question how far a salaried surveyor is entitled to separate remuneration for particular work. In this case the surveyor had been employed as architect in the Borough Gaol Extension, and he claimed £427 as architect's commission at 5 per cent. upon the total outlay. After a long discussion as to whether the work done was extra-official or not, a motion that the charge should be paid was unanimously adopted.

The construction of the buildings in the rear of Burlington House for the London University and the picture galleries of the Royal Academy has rapidly progressed, and the contractors are sanguine that the latter will be completed for the opening of the exhibition in the spring of next year. The structures in the forecourt in Piccadilly (with the exception of the mansion itself) have been within the last few days cleared away to make room for an edifice 60ft. in height, which is to occupy the front and two sides, and thus form a quadrangle after the manner of Somerset House. In this building the Royal Linnean, Geological, and Astronomical Societies and the Society of Antiquaries are to be lodged, and thus, in close proximity, the whole site will contain the headquarters of science, learning, and art.

The Town Council of Portsmouth have been obliged to call in advice as to the construction of their drainage works. At a meeting held on Friday last it was resolved that Mr. Hawksley be engaged to report to the Council on the present state of the drainage of the borough, and what he considered desirable to effectually carry it out.

Arrangements, we understand, have been made for commencing classes throughout the entire coal district for teaching technical and scientific subjects, in connection with the Government Department of Arts and Sciences. Classes will be opened at once at Blyth, Sunderland, Newcastle, Hetton, and Bishop Auckland, and will be followed as fast as suitable masters can be obtained by classes at Seaham, Rainton, and all other populous places. The subjects taught will be machine drawing, navigation, mathematics, chemistry and geology, building construction, applied mechanics, steam mining, &c.

The eleventh session of the Edinburgh Architectural Association was opened on Wednesday week with a lecture delivered in the Craigie Hall, St. Andrew-square, by Mr. John D. Marshall. There was a good attendance of members and their friends. The chair was occupied by Mr. J. Ballantine, jun., president of the association, who briefly introduced the lecturer. The subject of Mr. Marshall's lecture was "Taste and Style as applied to Ornamentation." A number of photographs, &c., were exhibited during the evening, including photographs of competition designs for Government Law Courts in London, which were kindly lent by Mr. David Bryce, R.S.A.

Patents for Inventions

CONNECTED WITH THE BUILDING TRADE.

459 C. and L. VERHULST. IMPROVEMENTS IN THE ARRANGEMENT AND CONSTRUCTION OF FIREPLACES. (A communication.) Dated February 11, 1868.

This invention consists in bringing the firegrate forward into the apartment to be warmed, and in applying thereto a movable hood or apparatus to prevent the escape of smoke; also in an improved valve or damper for regulating the orifice between the firegrate and the chimney. The whole firegrate is made to project beyond the line of the chimneypiece, so that the warmth may be distributed in the apartment more advantageously than heretofore, and the hood is constructed so as to cover the firegrate, or partially cover it, or leave it entirely uncovered, as may be found necessary. The hood is supported on inclined rails, and it is counterbalanced by a weight passing over guide pulleys, the position of the hood being regulated by a handle projecting through the front of the chimneypiece. The valve or damper to regulate the draught consists of a swivel plate provided with counterweights, and its position is also regulated by a handle passing through the front of the chimneypiece.—Patent completed.

482 J. TOWLE. IMPROVEMENTS IN THE ARRANGEMENT OF SEWERS AND DRAINS FOR THE COLLECTION AND DISTRIBUTION OF SEWAGE MATTERS. Dated February 12, 1868.

Here the inventor proposes to carry off the storm waters of towns by means of a separate small barred drain, or pipes of suitable material and size, according to circumstances, laid under the present rain-water gutters, close to the kerb of the footpath, one on each side of the way, except the street be a narrow one. These drains are to be laid as shallow as possible, so as to be safe from injury by carriage wheels, and for the obtaining of one uniform fall.—Patent abandoned.

515 L. MUMMENHOFF. IMPROVEMENTS IN THE MANUFACTURE OF BUILDING BLOCKS, AND FOR USE IN BUILDING. (A communication.) Dated February 15, 1868.

Here the patentee combines together ashes of coal and coke and Portland cement, or Roman cement, or other similar cement, and he also combines with the mixture other materials, varying according to the purpose for which the block or composition is required. Thus, for use out of doors and in massive structures, he employs ashes of coal or coke, cement, slag, lime and water glass. For use inside buildings, as for fireproof arches, and for other purposes, he uses ashes of coal or coke, cement, slag, and lime, without water glass. For use inside buildings for lighter purposes he uses ashes of coal and coke, slag and lime. For use in structures exposed to water, for building cellars, and for similar purposes he uses ashes of coal or coke, cement, slag, lime, and river sand. The prepared materials may also be used for flooring.—Patent completed.

525 J. WALKER. IMPROVEMENTS IN THE MANUFACTURE OF ORNAMENTAL TILES, SLABS, BRICKS, AND OTHER ARTICLES. Dated February 17, 1868.

According to this invention, the patentee perforates the absorbent mould in the parts where it is recessed, in order to form the pattern with small holes which serve to supply the air more freely between the die or mould and the moulded tile, and cause the two to separate more readily. Also in place of filling the mould as usual, he forces it upon a batt or slab of clay or clays by means of a press or otherwise, and the requisite impression is thus formed on the batt or slab of clay or clays the holes giving free escape to the air, and allowing the clay to penetrate into all the recesses of the mould afterwards in the usual way. The hollows in the moulded slab or batt of clay or clays are filled in with clay of another colour or colours, and the tile is finished as heretofore. The same process of manufacture is applicable to slabs, bricks, and other articles.—Patent completed.

528 W. R. LAKE. IMPROVEMENTS IN KILNS. (A communication.) Dated February 18, 1868.

This invention relates to a method of burning or baking bricks, tiles and other articles by passing them on trucks or moving platforms through a long tunnel provided with means for regulating the temperature, whereby the bricks or other articles are heated and cooled gradually during their passage through the tunnel. The improvements consist, chiefly, in the peculiar construction of the kiln or tunnel, in the means for effecting the gradual heating and cooling of the bricks thereio, in the novel construction of the trucks or platforms for carrying the bricks, and in the devices for controlling the motion of the trucks and for adjusting them in any desired position in the kiln.—Patent abandoned.

541 H. CHAMBERLAIN. IMPROVEMENTS IN THE MANUFACTURE OF COMPRESSED BRICKS, AND IN THE MACHINERY OR APPARATUS EMPLOYED THEREIN. Dated February 18, 1868.

This invention consists, essentially, in pressing the brick two or more times, and each time in a fresh mould, so that the second pressure which is exerted upon a brick delivered from the first mould in the more or less defective state usual in dry brick moulding, perfects the article by completing the expulsion of the confined air, and equalising the density of the brick, which, according to this invention, is turned over or reversed whilst passing from one mould to another, and, consequently, becomes equally pressed on the top and bottom surfaces.—Patent completed.

550 W. H. STEEL. IMPROVEMENTS IN HAND SAWS FOR CUTTING DOVETAILS AND OTHER PURPOSES. Dated February 19, 1868.

The patentee claims the improved construction of handsaws for cutting dovetails, and for other purposes, in which part of the blade plates are turned up or project sideways at suitable angles to the main portion of the blades, on which angular or projecting part ordinary saw teeth are formed, for the purposes substantially as described.—Patent completed.

553 W. R. LAKE. AN IMPROVED PROCESS OF SEASONING AND PRESERVING WOOD. (A communication.) Dated February 19, 1868.

This invention consists, chiefly, in treating the wood with a boiling solution of borax in water, which easily and effectually dissolves and removes all those perishable substances without injuriously affecting the wood fibre, which, on the contrary, becomes hard, impregnable to water, vermin proof, perfectly indifferent to the moisture or dryness of the atmosphere, and almost indestructible.—Patent completed.

588 A. DE METZ. IMPROVEMENTS IN POTS OR VESSELS TO BE USED AS WATER CLOSETS. Dated February 22, 1868.

These improvements have reference to portable or fixed vessels constructed of a material or materials which would at the seat present an uncomfortably cold surface to the sitter or person using them (as, for instance, metal or earthenware), and comprise the construction of such vessels at the seat with an inner top of some comparatively low heat conducting quality (such as, for instance, papier mache, felt, or gutta percha) fixed to or forming part of the body of the vessel itself.—Patent abandoned.

Trade News.

TENDERS.

BATTERSEA.—For building presbytery at Battersea, for the Right Rev. Dr. Grant. C. A. Buckler, architect:—
B. E. Nightingale (accepted) £800

BROADSTAIRS.—For repairs, &c., to Nos 2 and 3, High-street, for Mr. Chapman. Mr. John R. Collett, architect:—
Hiller £275
Blackburn (accepted) 230

BUCKINGHAMSHIRE.—For rebuilding chancel and adding vestry to Ellesborough church, Buckinghamshire. Fredk. Preedy, architect:—
Cooper £1186 10
Haddon 1100 0
Fitkin 1040 0
Holland (accepted) 1000 0

CATERHAM (Surrey).—For alterations and additions to the Manor House, for Mr. G. Parbury. Mr. Richard Martin, architect. Quantities not supplied:—

Blyth	£2375	...	£ 95	...	£2280
Ward	2368	...	159	...	2218
Regis (accepted)	2220	...	130	...	2090

GLOUCESTERSHIRE.—For the restoration of Mickleton church, Gloucestershire. Fredk. Preedy, architect:—
Espley £1972
Tomes (accepted) 1620

HUNTINGDON.—For rebuilding north aisle and restoring part of Yelling church, Huntingdon. Fredk. Preedy, architect:—
Thackray (accepted) £519

ISLE OF ELY.—For the restoration of Sutton church, Isle of Ely, Cambridge. Fredk. Preedy, architect:—
Freeman Brothers ..... £.531 10 0
Bell and Sons 2344 0 0
Bennett 2.00 0 0
Bardell and Son (accepted) 2153 6 6

KINGSTON-ON-THAMES. — For Sewerage Extension at Kingston-on-Thames. C. Slagg, Borough Engineer:—
Wigmore £2349
Morton 2325
Walker 2316
Wells 2145
Harris 2090
Robinson 2090
Voss 2032

LONDON.—For rebuilding a warehouse, No. 15, Watling street, City, E.C. Mr. Herbert Ford, architect. Quantities supplied:—
Lawrence and Sons £2557
Myers and Sons 2409
Burton and Moreland 2102
Conder 2313
Pritchard 2306
Ashby and Sons 2295
Browne and Robinson 2263
Henshaw 2256
Brass 2119
Webb and Sons 2103
Piper and Wheeler 2047
Crabb and Vaughan (accepted) 1994

MAIDENHEAD.—For putting new roof and attics to Stubbings House, Maidenhead, for H. D. Skrine, Esq. Fredk. Preedy, architect:—
Silver (accepted) £1080

NEWBURY.—For building nine mechanics' cottages, for Mr. W. H. Care. Including old materials. Mr. J. H. Money, architect:—
Church £1390 10
Sargent 1120 0
Elliott 895 0

WORCESTERSHIRE.—For building chapel of ease, Hollybush, Castle Morton, Worcestershire. Portion of materials given. Fredk. Preedy, architect:—
Hughes ..... £:28 0
Walt and Hook 640 0
Garbutt 632 10
Inwood 597 0
Griffiths 595 0
Smart 583 10

COMPETITIONS.

INDIA.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

LEICESTER WATERWORKS.—December 8.—For the construction of a large storage reservoir, &c., and for the erection of an engine and boiler house, and other works. J. H. Williams, secretary, Waterworks offices, Bowling Green-street, Leicester.

ST. MARY CHURCH, TORQUAY (Devon).—November 19.—For the erection of new gasworks in the Barton-road. Grant Wolleo, clerk to the local board.

PENZANCE.—November 28.—For the improvement of the harbour of Mousehole, in the parish of Paul, near Penzance, in Cornwall. Rodd and Cornish, solicitors to the Commissioners, Penzance.

ROCHDALE.—November 24.—For lighting the new townhall with gas. T. Mellor, town clerk.

ROCHDALE.—November 24.—For warming and ventilating the new townhall. T. Mellor, town clerk.

TOWER SUBWAY COMPANY.—November 30.—For the construction of lifts. Mr. P. Barlow, engineer, 26, Great George-street, S.W.

TRINITY HOUSE, LONDON, E.C.—For the supply of dressed and scappled granite for new lighthouse at Longships rock. R. Allen, secretary.

BRADFORD.—November 23.—For the erection of thirty shops in Godwin street. Lockwood and Mawson, architects, Exchange, Bradford; 10 Lincoln's Inn Fields, London.

METROPOLITAN BOARD OF WORKS.—November 20.—For the construction and maintaining in repair of certain brick sewers in Hammersmith. J. Pollard, clerk, Spring-gardens, S.W.

MARYPORT.—November 30.—For laying street gas mains, and for excavating, restoring, and sustaining the streets. J. Barwise, Harbour Office, Maryport.

For an iron bridge of two spans. J. C. Laryon, 58, Gresham House, Old Broad street.

November 30.—For the erection of a block of model buildings, near Tottenham Court-road. Mr. S. Legg, architect, 32, Bedford row, W.C.

HAMPTON COURT AND WALTON BRIDGES.—December 16. Tender for tolls. Mitre, Hampton Court.

PROPERTY SALES.

OCTOBER 27.

AT THE MART.—By Messrs. Debenham, Tewson, and Farmer.—Freehold and leasehold properties, situate in Shoreditch, Whitechapel, Dalston, Lower Clapton, Tottenham, and Stoke Newington, in 19 lots:—

Lot 1, sold for £5,700; lot 2, £600; lot 3, £330; lot 4, £330; lot 5, £410; lot 6, £490; lot 7, £470; lot 8, £480; lot 9, £350; lot 10, £350; lot 11, £460; lot 12, £440; lot 13, £320; lot 14, £330; lot 15, £310; lot 17, £330; lot 18, £630; lot 19, £910.

Freehold 9a. 0r. 24p. of building land, situate at Addlestone, Surrey—£1,050.

Freehold 10a. of building land, situate in Liberty lane, Addlestone—£650.

Freehold 2a. 2r. 10p. of building land, situate at Roydon, Essex—£110.

OCTOBER 28.

At the Mart.—By Messrs. E. Smith and Co.—Leasehold residence, No. 17, Ampthill square, term 74 years unexpired at £10 10s. per annum—£840.

OCTOBER 29.

At the Mart.—By Messrs. Smith, Son, and Oakley.—Freehold wharf and waterside premises, known as Limehouse Dockyard, situate at the end of Limehouse reach, fronting the Thames, and embracing an area of 111,228 square feet, with two houses, cottage, warehouses, and sheds—£25,000.

By Messrs. Dowsett and Chattell.—Freehold residence, known as Melbourne Villa, Queen's road, Norbiton hill—£810.

OCTOBER 30.

At the Mart.—By Mr. Dale.—Freehold house, No. 1, Salter street, Limehouse, let at £27 per annum—£265.

Leasehold four houses, Nos. 8 to 11, Chapel terrace, Tredegar road, Mile end, producing £103 per annum, term 73 years unexpired, at £3 5s. each per annum—£1,035.

Leasehold eight houses and shed, in Bloom street, Mile end, producing £103 17s. per annum, term four years unexpired at £16 per annum—£90.

Leasehold four houses, Nos. 15, 16, 18, and 19, St. Dunston's road, Mile end, producing £67 12s. per annum, term 82 years unexpired, at £18 per annum—£370.

NOVEMBER 3.

At the Mart.—By Mr. Charles Lindo.—Leasehold four houses, one with shop, situate in Markfield road, Tottenham, term 99 years from 1865 at £8 per annum—£190.

By Messrs. Debenham, Tewson, and Farmer.—Leasehold warehouse, No. 30, St. Paul's churchyard, let on lease at £600 per annum, term 80 years from 1854, at £350 per annum—£3,200.

NOVEMBER 6.

At the Mart.—By Messrs. Norton, Trist, Watney, and Co.—Leasehold stabling, No. 8, Somers mews, Hyde Park, term 63½ years unexpired, at £5 per annum—£620.

At Garraway's.—By Mr. R. Reid.—Leasehold residence, known as Wellesley House, Church road, Upper Norwood, annual value £175, term 99 years from 1864, at £32 per annum—£1,650.

Leasehold residence, No. 43, Adelaide road, Haverstock hill, let at £75 per annum, term 77 years unexpired, at £2 per annum—£940.

Leasehold residence, No. 24, Albert street, Regent's Park, let at £52 10s. per annum, term 73 years unexpired, at £5 10s. per annum—£680.

Leasehold house, No. 21, Campbell street, Hall Park, Edgware road, annual value £38, term 70 years unexpired, at £7 per annum—£335.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

Joseph Ingall, Charles street, City road, house decorator, November 26, at 12—Alfred Muncey, East Acton, architect, November 25, at 12—John Barnes, Gordon road, Peckham Rye, carpenter, November 24, at 1—William Crimp, Dale road, Kentish Town, carpenter, November 16, at 11—Mary Howard, Woolwich, contractor, November 18, at 12—Amos Scholfield, Jamaica Level, Rotherhithe, builder, November 24, at 1.

TO SURRENDER IN THE COUNTRY.

Owen Davies, Dolgelly, builder, November 23, at 11—William Jones, Maescaled, builder, November 23, at 11—William Joy, Tonbridge, plumber, November 23, at 10—Henry Thomas, Maesteg, carpenter, November 23, at 11—John Woolfrey, jun., Taunton, builder, November 21, at 12—Arthur Barrett, Donhead, St. Andrew, Wilts, stonemason, November 19—William Baxendale, Collyhurst, joiner and builder, November 26, at 11—George Winstone Broad, Horfield, Gloucester, builder, November 20, at 12—Edward Charles Meddle Walker and David Allen Jones, Liverpool, timber merchants, November 18, at 11—Abraham Willett, Tranmere, plumber and glazier, November 14, at 10.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

December 15, J. and W. Weeks, Dartmouth, builder—December 2, W. Whitehead, Sheffield, brick manufacturer—December 12, G. T. Spalding, Eaglesthorpe, brickmaker—December 12, A. Richardson, Peterborough, engineer—November 27, F. S. Donnelly, Russell road, Peckham, builder—November 25, E. Pike, Church street, Shoreditch, carpenter—November 27, C. F. Phelps, Russell road, Kensington, builder—November 17, J. Eaby, East Ham, building contractor—December 14, H. Ventham, Chapel street, Bedford row, builder—November 24, T. Gregory, Alfreton, Derbyshire, builder—November 23, T. and W. English, Peterborough, painters—November 28, A. Thick, Woolston, Hants, builder.

PARTNERSHIPS DISSOLVED.

Clegg and Taylor, Rochdale, joiners—Atkinson and Holmes, Noel street, Soho, gasfitters—Baker and Waldron, Battersea square, carpenters—Coates and Fletcher, Thrapston, builders.

DIVIDENDS.

November 20, B. Bottomley and G. Spencely, Halifax, stonemasons—November 20, F. Calvert, Halifax, plumber—November 16, D. G. F. Macdonald, Brighton, surveyor—November 25, W. Brown, Maryport, joiner.

THE CONTINENTAL MARBLE COMPANY,

IN consequence of the Metropolitan Railway having taken their old premises, have REMOVED to

7, WILSON-STREET, FINSBURY, E.C.,

Where Architects, Builders, &c., will find the largest Stock of MARBLE CHIMNEYPIECES and REGISTER STOVES in London.

MARBLE CHIMNEYPIECE & REGISTER STOVE £1 6s. 6d.

A LIBERAL COMMISSION ALLOWED TO THE TRADE.

W. H. BURKE AND CO.,

QUARRY PROPRIETORS,

MASONS, SCULPTORS, AND CARVERS IN MARBLE, GRANITE, AND STONE.

WORKS AND STUDIOS—17, NEWMAN-STREET, OXFORD-STREET, LONDON; RANCE, BELGIUM.

QUARRIES—IPPLEPEN, DEVONSHIRE.

GALLERIES—WARWICK HOUSE, 142 and 144, REGENT-STREET, 29, 30, and 31, WARWICK-STREET, W.

No charge for estimates. Specimens of foreign and British marbles on application.

PENRYN GRANITE QUARRIES COMPANY (LIMITED)

1, CHATHAM PLACE, BLACKFRIARS BRIDGE, LONDON, E.C.,

AND AT

PENRYN, CORNWALL.

THIS Company is prepared to SUPPLY GRANITE of the Finest Quality in any Size and Quantity. The Granite from the Quarries of this Company has been Selected by the Metropolitan Board of Works for the upper courses of the Thames Embankment.

O. C. SILK, Secretary.

JOHN FREEMAN AND SONS,

GRANITE QUARRIERS AND MERCHANTS,

OFFICES, PENRYN, CORNWALL.

Quarries at Penryn, Penzance and Cheesewring. Steam Machinery at Penryn and Liskeard.

Communications for Prices may be addressed to the Offices at Penryn; Messrs. Freeman, 27, Millbank-street; or Messrs. Tregelles and Taylor, 95, Cannon-street, London.

CHARLES GOODYEAR,

GRANITE MERCHANT,

Is Prepared to Supply from his Works known as

THE DE LANK GRANITE QUARRIES,

Stone of a Superior Quality for Engineering and general Building Purposes. Granite from the above Quarries is being extensively used in some of the largest engineering works now in the course of construction.

OFFICES: Country—Fore Street, Bodmin, Cornwall. London—19, Northumberland Street, Strand, W.C.

PAVING SETS.

THE WELSH GRANITE COMPANY (LIMITED)

Supplies the BEST SETS.

They Combine, more than any other Stone in the Market, the Qualities of ROUGHNESS and SAFETY with DURABILITY and ECONOMY.

Address, the MANAGER, Yr Eifl Quarry, Trevor, Caernarvon, North Wales.

W. & J. R. FREEMAN,

MERCHANTS IN ALL KINDS OF STONE AND GRANITE,

DEPOTS adjoining the Commercial Surrey Docks, Rotherhithe; Macclesfield-street, City-road; and Millbank-street, Westminster—where Estimates may be obtained for Deliveries, either by Vessel or Rail, to all parts of the Kingdom.

OFFICE—27, MILLBANK STREET, LONDON, S.W.

RANSOME'S PATENT CONCRETE STONE.

WHICH for STRENGTH, DURABILITY, CHEAPNESS, SHARPNESS of OUTLINE, BEAUTY of APPEARANCE, and above all for its PERFECT RESEMBLANCE to NATURAL STONE stands unrivalled, and being MADE WITHOUT BURNING is free from all liability to shrinking or distortion. It surpasses all other material in its applicability to ARCHITECTURAL EMBELLISHMENT, CAPITALS, CORNICES, WINDOW DRESSINGS, Trusses, Balustrades, Gate Piers, Te minals, Fountains, Vases, Jardinets, Statues, Flower Boxes, and Edgings for Garden Borders; also for Monuments, Tombs, and all kinds of Cemetery Requirements.

LICENSES GRANTED BY THE

PATENT CONCRETE STONE COMPANY, LIMITED,

2, QUEEN STREET PLACE, SOUTHWARK BRIDGE, LONDON, E.C.

WILLIAM ORME CARTER,

LIVERPOOL,

SLATE MERCHANT, QUARRY PROPRIETOR, AND MANUFACTURER OF ARTICLES IN SLATE.

SLATES for ROOFING of every Size and Quality, either Blue, Grey, Green, or Red, direct from the Quarries in Wales or Westmoreland, at wholesale prices in truck loads of not less than five tons.

SLATE SLABS, direct from the Quarries in Wales, at Wholesale prices, in truck loads of not less than five tons.

SLATE ORNAMENTAL ENAMELLED ARTICLES in imitation of the most costly marbles. Chimney pieces, Baths, Filters, Wall linings, Table tops, Columns, &c., &c.

SLATE PLAIN ARTICLES.—Working Squares and other Utensils for Brewing, Water Cisterns, Baths, Sinks, Shelving for Larders, Dairies, Greenhouses, &c., Lining and Shelves for Strong-rooms, Horse and Cow Mangers, Stall Divisions, Cattle Troughs, Pickling Troughs Pavements, Lavatories, Urinals, and all articles for Sanitary Purposes Billiard and Bagatelle Table Beds most carefully finished, and ridge roll plain and crested.

LARGE STOCK OF ROOFING SLATES ON HAND FOR EXPORT.

PORTLAND STONE COMPANY (LIMITED)

supplies direct from its Quarries

PORTLAND BLOCK STONE,

Of Fine and Even Texture, Sound, and Durable, in Blocks of any Dimensions, or Sawn in Slabs of Various Thicknesses.

PORTLAND ROACH STONE,

Extensively used for Dock and Sea Walls, Machinery Beds, Foundations, &c., in Blocks of all sizes, at a Low Price.

Stone can be forwarded either per Vessel, London and South-Western or Great Western Railways and their connections.

For Prices, Particulars, and Samples apply to the Manager,

MR. J. J. R. SHORT, ISLE OF PORTLAND, DORSET.

London Orders may be addressed to 10, PARK STREET, WESTMINSTER, S.W.

G. MITCHELL,

MARBLE, STONE, AND GRANITE WORKS.

SHOW ROOMS:—166, BROMPTON ROAD, LONDON, S.W.

Where Architects, Builders, and Merchants will find the largest and best stock of Chimney-pieces and Monuments in London, o which Books, Catalogues, and Sheets of Monuments will be forwarded on application.

Estimates will meet with prompt attention.

MANUFACTORY at WALTON STREET.

DEVON RED MARBLE WORKS, Teignmouth.

—Estimates furnished for all descriptions of Marble Works, to which the Devon marbles are applicable. The trade supplied in block and scantling. WILLIAM S. BINE.

London Agent: Mr. J. HARTLEY, Oakville, Maple-road, Anerley, S.E.

FOR MARBLE and STONE CHIMNEY-PIECES

14, CHATHAM PLACE, BLACKFRIARS ROAD, E.C.

THE BUILDING NEWS.

LONDON, FRIDAY, NOVEMBER 20, 1868.

ASSOCIATED ARTS INSTITUTE.

WE recently gave an account of the opening meeting of the present session of this comparatively new institution and a report of the address of its president, Professor Westmacott. We propose now to make a few remarks respecting each of these, in the same manner as that in which we lately reviewed the proceedings of the longer established bodies of our own profession—the Royal Institute of Architects and the Architectural Association.

In the first place, we fully recognise the wants to fulfil which this society has been established. That social intercourse and means of interchaugiog ideas supplied to architects by the flourishing institutions we have named, and many others which exist in the provinces, in Scotland, and in Ireland, seem hitherto to have been but very sparingly afforded to painters and sculptors. The Royal Academy and other societies of artists have quite different objects in view, viz., the exhibition and sale of executed works, and they are besides comparatively limited, and, in fact, closed to all but their own members. It cannot be questioned that architects and engineers have benefited greatly by the advantages of the kind referred to that they enjoy, while considerable public services may be traced to them; the success which is so marked a feature of all the societies established by these professions is perhaps the best proof that can be adduced as to their having been needed.

The want of similar opportunities has, we think, tended greatly to that condition of art in England which is thus summarized by Professor Westmacott: "We see much of originality of art arising from each artist pursuing the bent of his own inclinations, but all must admit that there is a great deal of want of association in all that they do." The truth of this observation must be patent to everyone who compared the gallery of modern British art at the Leeds Exhibition with either the ancient or foreign ones, and it was equally observable and very generally noticed in the International Exhibitions of London and Paris. On the continent a species of centralisation under the patronage and supervision of Government exists as a corrective for this particular evil. Artists are there educated in an academical groove which compels them to adopt a kind of unity in their practice. Such unity, it is true, is neither to be altogether admired or desired; that which we seek is voluntary and intelligent, the result of conviction and not of compulsion. Yet how shall a man hear if there be none to preach? The purpose of this class of associations is to provide the pulpit and to bring together the preacher and the hearers; but the Professor, rather unnecessarily, in our opinion, thought it incumbent upon him to apologise for this function of the Associated Arts Institute; for, in alluding to the existence of prejudices against such societies on the ground that they often ended where they had begun—in talk, he deprecated the idea of this being a debating society, and said "its members never meet until their work of the day is finished, when they meet to exchange opinions." For our part we confess the distinction seems to be one without a difference. We presume that the same might be said of every society of the kind; their meetings usually are held in the evenings, so as not to interrupt the business of the day, and we imagine that the method of exchanging opinions must be the same in every case, except it might be among the Quakers. We would advise the Professor at once boldly to admit the fact that it is for talk and the benefits accruing from it alone that the society has been formed, and that unless the members intend to exercise this vocation or that of listeners, they had better stay at home.

We can well remember, as an especial privilege, the having been admitted in years past as one of a brotherhood of artists who met in their own rooms without such formality, nor should we be consistent with facts if we gave an impression that anything else than talk was the main attraction of those assemblages; and we can at least speak for ourselves and attribute no small share of the knowledge we possess, of the principles we have adopted, and of the zeal which has enabled us to buffet with the world for those principles to the result of those discussions; and it is generally acknowledged that the entirely changed and improved character of the works annually exhibited may be traced to the effect wrought by those reformers, many of whom are now eminent, and we think that they were in no slight degree influenced by the agency which we have pointed out. We can recall to mind also many pleasant summer excursions to a locality frequented by young painters, and believe that we can attribute almost as much good to the criticisms and discussions which whiled away the evenings as to the more solitary work done during the days, for men may, and often do, go muddling on by themselves upon a wrong tack and be only wasting time, while they may get their eyes opened in a moment to the perception of the right one when in contact with others.

Now, such an association as the one we are noticing supplies in a regular and organised manner those opportunities which can only be enjoyed otherwise in a limited and desultory one, and, in a Darwinian sense, it will act far the more powerfully, bringing more and differently constituted minds to bear on the same subject; for it is but natural that in the meetings of friends it will be mainly "birds of a feather that will flock together," and then they foster each other's prejudices rather than confute and disperse them. In the more general meetings of societies, on the contrary, all are not likely to be of one mind, and every subject is sure to be viewed, as it should be, from various and even opposite points.

Had the young pre-Raffaelites, whom no one can deny to have left their mark on the age, been obliged to wrangle in such an arena, to maintain their new doctrines among a larger and less sympathetic circle, they would have had fewer pricks to kick against in actual life; for most of what has been proved to have been chaff by the painful experience of failure would have been winnowed away, and what all now allow to have been wheat would, perhaps, have been more readily acknowledged and prized. As it was, having none to contradict them, they persuaded themselves they were wholly right, and though the truths for which they fought have largely prevailed, they have been obliged to give up as error much of that which they put forward then with equal pertinacity, and which greatly retarded their own progress and impeded the good which they might have been able to effect.

It is, however, not only with reference to their own brethren in art that painters and sculptors need to learn and practice that "renunciation of self" inculcated by Professor Westmacott; they require to have far more intimate relations and sympathies with the public than they have at present, and also with the professors of other branches of art, and particularly with architects. All suffer alike by the isolation with which they have been so long content, and there are few better means of counteracting this evil than such associations afford. At present it seems all haphazard as to whether the pictures painted by artists are such as the public need, so that, when finished, they may or may not be sold. We think we should be tolerably safe in saying that the majority are practical mistakes, and that even if purchasers be found, the pictures prove unsuitable to the positions or the light which alone can be provided for them, so that a grievous waste of power is the result. How much of this might be obviated if there were more of communion between artists and their patrons!

Another evil is that painters are occupying themselves in the multiplication of *tableaux de genre* upon petty canvases till they become a drug in the market, while the decoration of our walls and our windows, which we do want painted, are left in the hands of mere tradesmen, and too generally are disfigured with mere caricatures of art. The wholesome fusion of the amateur and artistic elements contemplated by the Associated Arts Institute may therefore be productive of mutual advantages, and the interchange of ideas, by which the former class no doubt will allow that they at least will benefit, may, we think, act not less beneficially on the latter.

Considering the short period which has elapsed since the foundation of the society, it has met, we think, with an encouraging degree of success, and certainly seems to stand alone among societies of the kind in point of economy; and although it is contemplated to double the amount of subscriptions (now only five shillings per annum), the advantage of so doing will be obvious if it will enable the discourses and discussions to be published. There can be little doubt that there will be no lack of subjects suited to the special consideration of its members. The history of ancient art, the lives of painters and sculptors, the characteristics of various schools, the best means of preserving or restoring those works which have been handed down to us from past times, the experiences of living artists as to the various methods of painting, particularly with reference to architectural decoration and its permanence, the value of the various pigments manufactured for them, and numerous other questions may be debated at the meetings of the Institute with great practical advantage.

GEOMETRICALLY DETERMINING THE STRESSES IN GIRDERS AND ROOFS.

SOME time ago, in 1865-6, Professor Culmann, filling the chair of Civil Engineering at the Zurich Polytechnic school, published, under the name of "Graphical Statics," a geometrical mode of determining the stresses in structures which deserves the greatest attention from practical engineers and architects. It is a process in which geometrical construction is substituted for complicated calculations; or, in other words, by which a great saving in time can be effected, together with a self-evident avoidance of liability to error. It will be seen that this process enables the architect or engineer to instantly note the effects of any alteration he may chance to make in his designs. As is seen one example we have chosen is that of the well-known case of a common Warren girder.

We are often asked to indicate the means of determining the strengths of frames, and the simple and yet correct plan we explain may serve as a general answer to a great number of such inquiries. In order to do this we have been obliged to begin by stating the principles on which these constructions are based; and we will proceed as soon as possible to their practical applications. These extremely useful and simple methods are not so generally known in England as they deserve to be, though on the continent, and especially in Switzerland, they are beginning to be very extensively applied. A very particular advantage of this method is its applicability to cases which cannot be easily, if at all, reached by calculation. We have thus been enabled to apply it to the determination of earth pressures in general, as in embankments and tunnels, &c., to scaffoldings, &c.

The basis of the method is simply that of the

almost popularly known principle of the parallelogram of forces. It is well known that a force can be geometrically represented by a *straig t* line running parallel to the given force, and denoting the amount of the force by its length. Of course a line *per se* cannot exactly denote a force, but if the course of the force or its direction from (say) right to left be also held to be indicated by the line, then all the required qualifications are given. Let us suppose, for instance, that we have a number of forces acting in a plane upon the same point. We then have, as indicated in the following diagram, to find the resultant of any number of given forces 1, 2, 3, 4, 5, acting upon one point, as indicated in fig. 1 :—Draw a polygon O *a b c d e* with its sides 1, 2, 3, 4, 5, parallel to the directions and equal to the magnitudes of the forces. These must be so arranged that if we indicate the courses of these forces in all the sides by arrows, all these arrows must point in the same course round the irregular polygon. The line R, closing this polygon by joining the origin O with the end *e*, represents the required resultant in direction and magnitude.

FIG. 1.

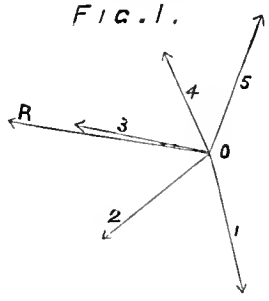

FIG. 2.

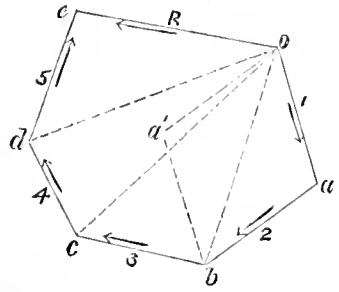

This resultant is to be taken in a course opposite to the curve of the given forces. Any one of the diagonals in the polygon represents the resultant of all the forces placed between the two points formed by that diagonal. This polygon may be termed the "polygon of forces," and it can be proved by successively combining the forces according to the principle of the parallelogram of forces.

If the polygon of any given number of forces, acting upon the same point, is closed, these forces will balance each other ; and *vice versa*. This is substantially the same proposition as that stated by Dr. Rankine, par. No. 53 of his "Applied Mechanics."

To determine two forces of given direction so that they may balance any number of known forces, all acting upon the same point, construct the polygon of the given forces and close it by two lines parallel to the directions of the given forces. These lines taken in the same direction round the polygon as the others represent the required forces. The second principle is a consequence of the first, and the third is easily proved by the second. With the assistance of these principles it is easy to ascertain the stresses on a Warren girder. To explain the process it will be sufficient to determine the stresses in a small girder constructed with only four divisions in the top beam, as shown in fig. 3. There will be no difficulty in afterwards extending this to larger girders.

We will designate its parts by numbering the connecting points, and by calling each bar lying between them by the numbers at its two

FIG. 3.

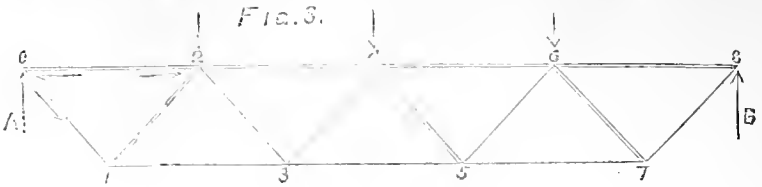

FIG. 4.

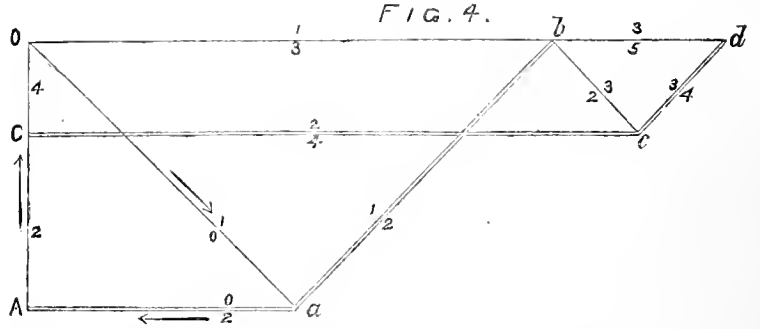

ends. We assume that the girder is loaded with ten tons at each connecting point of the top ; that is to say, at the points 2, 4, 6 ; while the resistances A and B of the supports act upon the extreme ends 0 and 8. As the load has been assumed to be uniformly distributed, each of these two resistances is equal to half the entire load of 30, or equal to 15 tons.

It is a necessary property of any structure that all the forces acting upon the same connecting point should be in equilibrium ; and we employ this property to ascertain the stresses in the different bars. If all the forces acting upon such a point are known with the exception of two, these two can be ascertained by means of the last principle stated. We begin at the point O, where the resistance A, equal to 15 tons, acts upwards, and we will proceed to determine the stresses in the bars 0 1 and 0 2, the directions of which are given. We draw the vertical line OA, fig. 4, parallel to the force A in fig. 3 ; and make it, by any scale, equal to 15 tons. The line A *a* is then drawn from A parallel to the horizontal bar *o*2 ; and line O *a* parallel to the sloping bar *o*1. These intersect one another at *a*. Therefore, the lines A *a* and O *a* respectively give the required amounts in tons of the stresses on the bars O 2 and O 1. They are of 15 tons and 21.2 tons. The curves of these forces only remain to be determined in order to know whether the bars have to sustain tension or compression. For this purpose, as we know the course of the force O A, which is indicated by an arrow, we have only to follow round the polygon of forces, which is in this case represented by the triangle A O *a* A, and to draw arrows in the directions in which we follow the sides O *a* and A *a*. By drawing other arrows in fig. 3 parallel to the corresponding arrows in fig. 4 we see that the stress in the bar 0 2 in fig. 3 acts against the point 0 ; and that the bar 0 2 has consequently to undergo compression. Further, the force in 0 1 strives to pull the point 0 towards 1, testifying to a tensile stress. For the sake of clearness we shall henceforth indicate tension by a single and compression by a double line, both in the elevation of the Warren girder and in the polygon of forces. By this means the course of the forces can be seen both in the elevation and by comparing both figures also in the polygon of forces. We must observe that in the elevation the stress acts on an extremity of the bar in a sense opposite to that in the other.

We now come to the point 1. We have here, besides the last determined force in 0 1, the unknown stresses in 1 2 and 1 3. The stress in O 1 is given in fig. 4 by the line 0 *a*, and its sense is now contrary to that indicated by the arrow. Proceeding as before, we draw O *b* parallel to 1 3 and *a b* parallel to 1 2, and cause them to intersect at *b*. The lines O *b* and *a b* give the stresses in 1 3 and 1 2 of 30 tons and 21·2 tons respectively. We determine the courses or senses of these stresses from the known sense of 0 1, following round the triangle *a* O *b a* in the direction given by the order of these four letters, and we find that the bar 1 3 is in tension and the bar 1 2 in compression.

In the points O and 1 only one known and two unknown forces were in action ; but in the point 2 three known forces (the stresses in O 2 and 1 2 and the load of 10 tons) and the unknown stresses in the bars 2 3 and 2 4. To ascertain these, set off from A to C in the line A O the length representing 10 tons and C *c* and *b c* parallel to 2 4 and 2 3. These two lines then give the magnitudes of the required forces, because the sides of the polygon C A *a b c* C are parallel and equal to the forces acting on the point 2. They are also taken in the right sense, which is the reverse to the order of the letters C A *a b c* C. We find that 2 3 has to sustain a tension of 7·1 tons and 2 4 a compression of 35 tons.

The same proceeding is to be used at the point 3 4. The two known forces (1 3 and 2 3) are already placed together in the right curve in the diagram fig. 4 ; they are represented by the lines *c b* O. The lines *c d* and O *d*, drawn parallel to the directions of the unknown stresses through C and O, meet each other in *d* and give the stresses in the bars 3 4 and 3 5, amounting to 7·1 tons and 40 tons respectively. The first is a compression, the second a tension bar. This gives us the strains up to the middle of the girder, and as the girder and the load are symmetrical we do not require to continue the diagram.

This fig. 4 may be called the diagram of forces. The polygons for each connecting point in the first half of the girder are laid down in it, and, observing how they are combined, we find that the polygons for the preceding points give the forces always arranged as required for the construction of the polygon of forces for the following point. The whole diagram hence contains each force only once, while every line would have to be drawn twice if we construct a separate polygon of forces for each connecting point. What makes this diagram of forces so very useful is that there is a minimum number of lines to be drawn, and that the construction can be rapidly carried out without any liability to error.

In conclusion, we may add that, should we meet with the requisite encouragement from our readers, we intend to give several other practical applications of the method, as it appears to us of much practical importance.

PORTLAND CEMENT.*

PORTLAND cement, after passing through a severe ordeal, involving testing, analysis, and the alternate condemnation and

* A Practical Treatise on the Manufacture of Portland Cement. By HENRY REID, C.E. To which is added a translation of M. A. Lipowitz's work, describing a new method adopted in Germany of manufacturing that cement. By W. F. REID. London: E. and F. N. Spon, 48, Charing Cross. 1868.

approval of many of those who considered themselves judges of such matters, may now be fairly ranked as among the most important of our constructive materials. It would, in all probability, have arrived at its present rank some years previously but for the reluctance of manufacturers to submit it to fair trial and experiment. The majority of them regarded their credit as affected by any imputation cast upon the quality of their goods, and it was not until necessity compelled them to submit the material to actual proof that they discovered their error. Manufacturers now, at least in a large number of instances, test their cement at the works, and are, therefore, in a position to furnish it of the strength that may be required. In the volume before us we have a complete history of the manufacture of Portland cement, and of the various examples of construction to which it has been applied. Some of our readers who are not professional men might desire to know briefly what this cement really consists of. It is made from the deposits of chalks on the shores of the Thames and Medway, mixed with alluvial clays from their estuaries and creeks. The composition of the former ingredient is well known, being simply a carbonate of lime; that of the latter includes silica, alumina, carbonate of lime, oxide of iron, and soda and potash. Let us now follow the various processes that these two ingredients are subjected to before they constitute actual Portland cement. The first operation consists in "washing" them, which is accomplished by a wash mill, and signifies the proportionate and due admixture of the above named components. The liquid is kept in a state of continual motion by the action of the mill, while, at the same time, the knives cut, and the attrition of the substances is thus ensured. From the mill the semi-fluid material is transferred to the sample kiln, where it remains from four to five hours. The object of thus "sampling" it is to ascertain whether the correct proportions of the ingredients have been arrived at. An experienced workman can tell by the colour, general appearance, and other signs intelligible to the practised eye whether the sample is properly constituted or otherwise. A register should be kept of all the samples, both those that have been tried in water and by air, and none should be destroyed before the expiration of a month at least. The German method of preparing the raw material differs from that employed in England, in it not being mixed up by the aid of water, but by machinery. The former may be termed the dry, and the latter the wet method. It would be out of place here to enter into the relative merits of the two plans, but it may be observed that Mr. Reid, on the whole, is in favour of the English system.

After the washed materials have remained a sufficient length of time in the "backs" or reservoirs to become partially consolidated, they are wheeled in barrows to the drying plates, where they are dried by the waste heat from the ovens for coking the coals used in burning the cement. The author draws attention to the expensive nature of this part of the manufacturing process, owing to the wear and tear occasioned by the constant great heat maintained and the alternate removal and replacement of hot and cold materials upon the drying plates. The best and most refractory bricks and tiles are rapidly destroyed by this intermittent action. From the drying plates to the kilns is the next step. The latter, after undergoing almost innumerable alterations and modifications, according to the fancies of inventors and patentees, have returned nearly to the same form they were originally constructed in. They hold from ten to seventy tons, their absolute capacity of course depending upon the extent of the manufacture and the rank of the firm. To drive off the carbonic acid, and to effect a partial vitrefaction of the material, are the objects of burning the cement or "clinker," as it is called, previously to the operation of grinding. The loading the kilns is performed by first laying down a small quantity of brushwood, and on the top of that a proportionate quantity of coke, and then filling up the kiln with successive layers of coke and raw material. No rule can be given for determining the time that may be required for burning the contents of a kiln, and it is also a difficult matter to arrive at a fair estimate of the cost. Mr. Reid mentions that under ordinarily favourable circumstances the fuel might be put down at about six shillings per ton. He also, very justly, comments upon the clumsy and inconvenient character of the kilns as constructed at present, and we join with him in hoping that a more satisfactory plan of accomplishing a very simple operation may be soon introduced. The burning completed, the kilns are drawn or unloaded, and the contents transferred to the grinding mill, to undergo the last step of being ground into the powder constituting Portland cement. Where crushing rollers are used for the above purpose they are capable of performing all the work themselves, but where edge runners are employed the lumps of clinker, which come from the kilns in all shapes and sizes, must be first reduced to smaller dimensions. This is best accomplished by a stone-breaking machine, which should have a power of about three horses. This method is preferable to the adoption of crushing rollers, where the material is very imperfectly prepared by manual labour for the machine, which is liable to be overstrained by the excess of work imposed upon it. There is a handy little American machine termed a "cracker" for reducing the clinker to a suitable size for the crushing machine. In whatever manner it may be accomplished there is room for improvement in this particular branch of the art.

Our author contradicts the usual notion entertained respecting the liability to deterioration of Portland cement by exposure to the air, and alleges that he has used that material after lying for two years in a well covered weatherproof building, and found it equal in every respect to that fresh from the manufacturers. From this there appears to be no especial advantage gained by storing up cement in casks, but quite the reverse, as wasting of the contents frequently takes place if the casks have been filled direct from the grinding mill, owing to the shrinking of the material in cooling. The operation of testing the cement may be considered as embracing three heads—firstly, the tensile resistance; secondly, the compressive strength or resistance to crushing; and, thirdly, the transverse strength or resistance to cross strain. As to the test of durability the fact is that the material has not been employed for a sufficient length of time to enable us to arrive at a conclusion upon the point. But from experiments instituted by Mr. Grant, it has been found that a period of twelve months is sufficient to more than double the strength of cement.

Among the various applications of the cement proper is that of employing it as a coating to the interior of iron vessels to prevent oxidisation and preserve the iron from corrosion. The use of the material in the shape of concrete, and its adoption by architects and engineers in retaining walls, harbour works, piers, foundations, and lately in house building, are too well known to require comment. Mr. Reid advocates its application to the formation of the surface of roads and streets, and instances two examples, one in Inverness and the other in Edinburgh, where the method was attended with success. He admits that in the case of St. James's Park the attempt was an unmitigated failure, but accounts satisfactorily for the want of success. At the same time we consider that further information is wanted to enable us to arrive at a decision upon this point. The second portion of the volume consists of a translation of a German work upon the same subject by M. A. Lipowitz, which contains a description of an endless kiln, and plan and sections of the machinery required. The plates are well lithographed, and the whole book sustains the reputation of the well-known publishers.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

ON Monday evening last, at an ordinary general meeting of the Institute (Mr. Clarke, vice-president, in the chair), Messrs. Edmund B. Ferrey and John Noyes were duly elected associates. A letter was read from the American Society of Architects, thanking the Institute for the gift of its "Transactions" to the library of the former, and asking acceptance of a series of photographs illustrative of the present condition of American architecture. Several donations in books and money to the library were announced, and a letter was read from Sir Sydney Smirke, stating that the Royal Academy would remove to its new rooms and hold its exhibition there next March, so that architects would be no longer cramped for room. There would be fourteen galleries, not one being less than 41ft. by 31ft. Sir Sydney Smirke expressed a hope that architecture would be well represented on that occasion as one of the "Three Sisters."

DISCUSSION ON TERRA COTTA.

The CHAIRMAN said that towards the close of the last session an interesting paper was read by Mr. Charles Barry on the use of terra cotta in building as exemplified in the new works at Dulwich College. So much interest was excited by that paper that it was resolved to adjourn the discussion of the subject to a meeting this session. He would first call upon Mr. Barry to open the debate.

Mr. BARRY said that it was commonly assumed that terra cotta was nothing more than baked clay, or baked clay and sand. Such a material did not deserve the name of terra cotta, and was not a worthy material for building purposes. An examination of the ancient terra cotta would show that the best Greek and Roman vases contained other elements than clay and sand. Great caution should be exercised by the architect in examining the terra cotta supplied, especially in large blocks, for when blocks were of considerable size some makers were tempted to make them of bad material and coat them over with good stuff. It was important that the material should be so compounded as to become homogeneous, and in producing large blocks it was essential that a face should be produced which would dry equally. One fruitful source of bad work in terra cotta was the insufficient time given to air-drying. This was so essential to the durability of the work that it could not be passed over slightly. The character of the manufacturer must be the main guarantee for the architect in good work. It had been stated by some that 3,000 deg. Fah. was the temperature necessary to properly burn terra cotta. One good test of the heat necessary was to fire it at the heat at which soft iron melted readily in the furnace. Faraday stated this to be 1,899, whilst Dr. Percy put it at 2,300. Terra cotta was far less a sorbent than any kind of stone.

Mr. BLASHFIELD said that Mr. Barry had taken such a deep interest in the matter that it would be felt one day that he had contributed very largely to the adoption of a new material of great value in architecture. His (Mr. Blashfield's) acquaintance with pottery grew from his intimacy with the late Herbert Minton, who had a patent for making buttons from porcelain. He pushed upon Minton the importance of making architectural pottery, and two or three and twenty years ago got him to make a block of bricks of an ornamental character and enamelled surface. He had great trouble to make him keep up with geometrical patterns. After some two years of experiment, Herbert Minton found that the machine for making buttons (made as the buttons were of dry powder) was the true machine to use, and the true way of working to make *tessræ*. The application of that machine was found to be very imperfect, and it was a long time before Minton could make an hexagonal tile 3½in. in diameter. Ultimately squares of 6in. were made. In 1850 he (Mr. Blashfield) began to make terra cotta. Any merit that his work might have was due primarily to his acquaintance with Mr. Minton, and to the experience he (Mr. Blashfield) had gained from observation in Staffordshire. His ware was more of a

pottery ware than the ware which was generally received as a building terra cotta. It was more the class of ware of which the encaustic tiles were made. It contained other elements than clay and sand—that is, it contained "pegmatite," which was a vague flux, and by the very careful use of old ware with these a body something like the Minton tile was gained, rather than the ordinary terra cotta of the present day. In doing this a larger expense was incurred for fuel than would be the case in the make of the open porous ware which was made for common terra cotta. The quantity of old ware which was mixed with the new materials was not determined. It would be a matter of the greatest possible utility if the authorities at South Kensington would call to their aid some scientific men to ascertain what the different qualities of clay would bear. In the manufacture of Portland cement there very often ran out of the kiln masses of a substance much resembling glass. In twelve months that mass began to speckle. After becoming speckled it began by degrees to give way, and then it went to powder. If this was set in water it became a cement that weighed 130lb. to the bushel, and took eighteen hours to set, but when it did set it was very hard. Without a flux in earthenware the body could not be held together. Chemists had examined old china and found a very large quantity of potash. In the Etruscan vases a considerable quantity of magnesia and peroxide of iron was found. These were fluxes. In some of the old Greek vases there was almost enough peroxide of iron to have brought them to a metallic state with the magnesia. In the old china manufactured by the Chinese there was combined a vast portion of "pegmatite," or China stone. In the wares he (Mr. Blashfield) had made of late he had tried as far as possible to imitate the mode of making porcelain. He had used the Dorsetshire clays with a given amount of flint, a given amount of old ware, so much glass, and so much China stone. With regard to the true ware he had to depend a great deal upon an operation which he performed after the ware had been air-dried. When it was quite dry he placed it in the hands of masons to cut and dress it and bring it to the desired form. It often happened that the material had really to be carved in its more ornamental portions. When perfectly dry the fine film which prevented some of the fixed air getting out was removed, and the ware was put in the oven, whence it came out all right. If a piece of the ware was put in the oven before all the surface was taken off it generally came out badly. If architects would encourage further examination into the use of certain materials, such as old broken ware, with pottery, or if the Government would do so at South Kensington, it would be of the greatest possible value, because certain facts as to the proper proportion of materials to be used in the manufacture of terra cotta might then be arrived at.

Mr. Redgrave was glad to be able to bring under the notice of the meeting some terra cotta largely used at Kensington, and which was entirely different in its nature to that used at Dulwich College. The question was not so much which was the best clay as which was the best terra cotta. Mr. Blashfield had brought his terra cotta to the highest degree of perfection. The goodness of terra cotta undoubtedly consisted in the firing. The common clay bricks burnt at Woolwich and Kensington were all terra cottas, and there were buildings in London built of these bricks which had lasted two or three hundred years entirely through the proper burning of the bricks. The clay of which the terra cotta which was used at Kensington was made was a clay found in the coal measures, well known as fireclay. The terra cotta which was being used at Albert Hall was almost entirely made of pure clay. Mr. Blashfield, however, thought this likely to decay. He (Mr. Redgrave) was glad that it became a question whether a mixed material or a pure material was most advantageous for the use of the architect. One great advantage of the pure material was that there was an unvarying rate of shrinkage; but, with the other material, unless the manufacturer and his workmen were most careful, they were liable to a false mixture, and consequently to a varying rate of shrinkage. Terra cotta, which was a brick brought to a great state of perfection, should be used in brick buildings. It might be used in stone buildings, but there it was a failure. Whether it was well laid or not, it was perfectly capable of receiving a glaze, and that glaze might be of various colours. With a perfectly imperishable vitreous glaze, which was most suitable to the architecture of London, terra cotta would meet with great favour. It might be brought to any degree of perfection by filing or grinding, and then might have its surface glazed, making it impervious to the action of the weather. Any colour might be attained at a very moderate cost, it needing only a second firing. Terra cotta must be a material in itself. It must not be a rival to brick or stone. It must be treated as a material the architecture of which was a speciality. As terra cotta was used in Italy a most beautiful surface, a variety of tint, and a high degree of colour could be attained—results which could not be arrived at in any other material. The failure of the use of terra cotta so far was due to imperfect knowledge.

Dr. Medlock had some acquaintance with the materials used in the manufacture of terra cotta and Portland cement. The latter was manufactured generally of three parts chalk and one part Thames mud. These were ground together and dried on a floor and burnt in a kiln. The cement made with the grey chalk at Wouldham was generally stronger and more durable than that made from the white chalk. With regard to the composition of terra cotta it was very difficult to express an opinion as to the proper compounds or the proportions of clay to be mixed to produce a certain material with an unvarying degree of hardness. It was done by "rule of thumb." Although the manufacturer might have the clays analysed he knew nothing of their fusion points, or whether they would form a flux. The manufacture of terra cotta was merely a matter of practical experiment. We knew nothing of the silicates, except that they combined in twenty, thirty, or forty different proportions. We knew nothing of the way in which they combined. The whole question of porcelain and pottery manufactures required to be most thoroughly investigated. As a chemist he said that we knew nothing of it. He hoped the time would come when all these questions would be examined by competent scientific authorities.

Mr. Canning characterised Mr. Blashfield's wares as a very successful issue of the "rule of thumb," considering that really and truly nothing was known of the materials which had to be dealt with. He (Mr. Canning) had to deal with the simple fireclay—a clay that was compounded by the Great Manufacturer, who had laid it in the coal measures to be modelled as the architect directed. This was done with a little of the same material burnt and mixed with it. He thought that if the manufacture of terra cotta was to be surrounded with many intricacies and difficulties it would never be brought to a convenient economical cost. The first object in the manufacture was durability. There could be no economy in using an article which was not permanently good. After twenty years' experience the terra cotta made from pure fireclay had not been found subject to any decay. The next thing was the colour. Fireclay produced an uniform colour of hard terra cotta; the tint was agreeable. His glazed terra cotta, which he named "Della Robbia," was the same as that made for South Kensington, which was made in an ordinary oven and fired three times.

Mr. Etheredge, in reference to a newly-found deposit of terra cotta clay which had been alluded to in Mr Barry's paper, said that it was the largest deposit in the world. It was of a nearly pure red colour, the same as that now used at Naples and throughout Italy. The quantity was positively inexhaustible. It stood 1,800 or 2,000 deg. uncommonly well. This deposit was found at Motcombe, in South Devon. The colour was not at all changed in the furnace. This was one of the most important discoveries made of late, for all Europe was at a loss for fireclays. At the present there was no such thing as a pure terra cotta clay. This was one of the softest clays imaginable, and some of the most beautiful objects in art had been attained by it. The shrinkage was scarcely perceptible.

Mr. Blanchard had seen the Motcombe clay, and it deserved great attention.

Mr. Doulton said that a simple test of the durability of terra cotta was to take a sharp-pointed instrument. If the terra cotta would turn the point of the sharp instrument it would be imperishable. It was undesirable for architects to seek for terra cotta decoration where there were many straight lines.

Mr. Page, C.E., said that he looked upon the works at Dulwich College as a revival of the art of building in terra cotta. As it partook of the nature of stone it might be introduced in a considerable measure in all buildings such as bridges. It was a material with which granite could not compare for durability. An examination of the balustrades of Waterloo Bridge would show the decay which was taking place there. He hailed with great pleasure (as an engineer who had paid great attention to art, and who hoped to see one day no engineering work which was not a work of art) the revival of the use of terra cotta.

Mr. Hayward narrated his experience of the use of terra cotta at considerable length, differing from the opinion that terra cotta was only suitable for brick architecture, for he had used it with success in conjunction with granite. Three triple-light windows, with balconies over, all in terra cotta, only cost £19 13s., and two single-light windows came to £4 7s. In parts where it was necessary to fill in the hollows, powdered terra cotta and Medina cement were used, at an additional cost of one-fourth the original price of the terra cotta. Mr. Blashfield's ware was used, and not one block out of £400 or £500 worth had been rejected. He (Mr. Hayward) had built granite on terra cotta, and if it should be found to fail he would let the members of the Institute know for their guidance. Of the durability of terra cotta there could be no doubt. The tower of Layer Marney Church, in Essex, of the date of 1521, contained a quantity of terra cotta in excellent preservation. He wished to know whether it was necessary that terra cotta should have such an extremely hard surface that it turned the edge of the chisel, and whether if terra cotta could be chipped by a chisel it would be a proof of inferiority in quality, because he had always understood that it was one of the advantages of terra cotta that it would bear to be chipped properly, and that if it was to be chipped accidentally it would not suffer any more than would stone.

Mr. Blashfield said that he did not think that hard-burnt terra cotta could be cut with economy, though a skilful mason might carve it.

Mr. Hayward: I want to know whether the fact of being able to carve it will militate against its durability.

Mr. Blashfield said it would not when "air-dried."

Professor Kerr moved a vote of thanks to Mr. Barry and to Mr. Blashfield, and the other manufacturers who had taken part in the discussion. When Mr. Redgrave argued that a natural clay was of necessity superior to an artificial clay his argument was scarcely borne out by facts. Artistically speaking, if the natural material was equally good with the artificial material, the natural one would be preferred. There was a certain capability of refinement in terra cotta which was very pleasing, but, looking at the nature of the material, it was certain that perfect refinement such as that attained in stone could not be attained. The question was whether we ought not to be satisfied with a little roughness, and let the more classical and refined work be given to the stonemason. Such was the late Captain Fowke's theory. Mr. Blashfield prefers to carve the surface of his work before burning. The question arose whether some other process could not be resorted to to serve this object of Mr. Blashfield's without sacrificing the artistic effort which was preferred at South Kensington. It might safely be said that the use of a red material as the sole material in a façade would be somewhat embarrassing, whereas the buff colour of the South Kensington models would be quite in accordance with the received notions of effect. The reds and the buffs might be used in combination. If the deposit of clay referred to by Mr. Etheredge was all of a red colour it would not supply the demand for terra cotta.

Mr. Barry was gratified to find he had started a subject which had attracted so much interest. He had indicated in his paper the way in which architects could assist in acquiring knowledge of the nature of terra cotta and its adaptability for building, and if some members of the Institute would go over the same ground as he had gone over, great good would result. The work at Dulwich College was produced in an essentially different manner to that made for Kensington. All the decorative work for Kensington was produced by casting in moulds. Now he thought that one of the advantages of the use of terra cotta was, that it gave facilities for having original works from the hands of artists, so that if high-art workmen were employed great beauty was attainable. This was infinitely superior to any work from moulds. When Dr. Medlock said that nothing was known about terra cotta, he (Mr. Barry) hoped he only spoke as a chemist, for practically a great deal was known, and whether

from "rule of thumb" or not, compounds had been found which were very durable. Unless, however, the material was homogeneous throughout its whole body, it would be worthless.

After some further remarks by Mr. Blashfield and Professor Kerr, the vote of thanks was unanimously accorded, and the discussion, which was unusually protracted, closed at half past ten o'clock.

FRESCO PAINTING IN GERMANY.

A WRITER in the *Pall Mall Gazette* says:—Fresco painting having been persistently practised in Germany for full thirty years, it is natural that the art has by this time extended over a wide area. Thus, as far north as Aix la-Chapelle do we come upon a series of eight wall pictures covering a surface of 3,000 square feet. These historic compositions, which commemorate the reign of Charlemagne—bold in conception, original in treatment—were commenced by Alfred Rethel more than thirty years ago. It is possible that the pigments may be deemed somewhat opaque, the colours crude, and the execution rather scratchy. Yet no one will venture to assert that the works are other than when they came from the artist's hands. They are substantially scatheless. They have, in short, escaped all that has befallen our English frescoes. They have not blistered, they have not peeled away; the colours do not lie on the surface loose as dust, to be brushed off from the walls. The sole injury I noted was an accidental scratch or scrape from a nail or ladder.

In like manner I am glad to report that Professor Bendemann's elaborate frescoes, which ten years since I saw in process of painting in the royal castle of Dresden, are well preserved. There are few more satisfactory and impressive examples of mural decoration in Europe than this grand throne room and its companion ball-room. On close examination a slight abrasion, crumbling away, or discoloration of the surface, may be detected in a monochrome frieze at the ceiling; that must be admitted. Perchance damp may have entered through a broken tile, or the mortar may at this spot have had something wrong in its constituent parts. The injury, at all events, was the result of a partial, not of a prevailing cause. There is, in short, every likelihood that these frescoes will, if tolerably well cared for, last for centuries yet to come.

The city of Spires I visited in order to make acquaintance with an imposing assemblage of frescoes, known to me only by engravings—the wall pictures wherewith Schraudolph, an illustrious disciple in the school of German spiritual art, has decorated the nave, transepts, and choir of the cathedral. In honesty I am bound to admit that while these mural decorations at Spires were only too crude and new, here and there slight discoloration was apparent. An opera-glass only could disclose the change, and the total damage would scarcely average one square inch in 20ft. It is just possible that this slight yielding to destructive agents may be the precursor to wider operations. Still I incline to the opinion that the damage is partial and accidental.

Remagen on the Rhine I revisited not without misgivings; but I found that since 1858 not the slightest change has appeared in the surface or quality of the frescoes. This absolute state of preservation was all the more unexpected from the extreme delicacy of the frescoes; they are not so much broad and sketchy as detailed, softly rounded, and highly elaborated.

To the above report may be added a word on the condition of the grand and gigantic "water glass" wall paintings now completed by Kaulbach in Berlin. It is well known that on the failure of frescoes in the Palace at Westminster the "wasserglas" process was adopted as a substitute, yet it is now understood that Mr. Maclise and Mr. E. M. Ward are dissatisfied with the results. It may, then, be important, not only that our artists, but that the House of Commons who have voted supplies, should learn that both Kaulbach and the people of Berlin are and have good reason to be perfectly content with the newly discovered process as exemplified in the vast "Treppenhaus" of the Museum. The effect is admirable, and the first picture executed is as sound as the last.

The above recital of facts seems to substantiate the following conclusions:—1. That in-door frescoes stand well in the German climate—a climate worse than the Italian, and equally as bad as the English. 2. That out-door frescoes in Germany, as in Italy, fall a prey to the elements. 3. That frescoes in Germany, when not maltreated, are as permanent as easel pictures. 4. That thus it would seem that the Germans, more fortunate than the English, have really discovered and revived the lost art of Italian fresco painting, and that the art thus revived is zealously practised down to this very moment. In proof of this last assertion I may quote four vast frescoes recently executed in the new museum of Cologne, by Professor Steinle, the master of our English Academician, F. Leighton. Also must not be forgotten a wide acreage of wall paintings designed and completed within the last five years in the National Bavarian Museum at Munich. These recent achievements indicate that in Germany faith remains unshaken in the permanence of the fresco process.

It is fair that I should add as almost a solitary example of the endurance of fresco in England, certain wall pictures by Mr. Watts, in the dining-room of a private dwelling in Carlton-terrace, London, where, be it observed, gas is not burnt. When I last examined these works, some six months ago, they were as fresh and uninjured as any frescoes in Germany.

ARCHITECTURAL ASSOCIATION.

THE usual fortnightly meeting took place on Friday evening last, Mr. W. White, F.S.A., president, in the chair. After the nomination of some new members, a vote of thanks was passed to the contributors of drawings and other objects of interest at the late *conversazione*, Mr. Phené Spiers remarking, in reference to the embroidery exhibited by Mr. Brangwyn, of Bruges, that it had been brought to its greatest perfection by a present member of the Association. Mr. Brangwyn only left England four years ago to establish himself as an architect, and had established a manufacture of embroidery, the design of the ornament of which carried off the gold medal at the Paris Exhibition.

Mr. J. D. MATHEWS said that by the kindness of the architects, Messrs. Lee Bros. and Payne, the members of the Association would visit the works at the new Her Majesty's Theatre on Saturday (to-morrow) at three o'clock.

Mr. SPIERS said that at the next meeting a report of the Architectural Alliance upon architectural education would be brought forward, and he should also take the opportunity of bringing forward the Society of Arts' report upon technical education.

Mr. M. DIGBY WYATT, F.R.I.B.A., F.S.A., &c., then read an elaborate paper on "The History of the Manufacture of Clocks, and of the Structural Arrangements made for their Display and Preservation, with Practical Rules for the Guidance of Architects in the Present Day." After giving an interesting sketch of the history of clock-making, which was the first division of his subject, he proceeded to the second section, stating that

It was not until a comparatively recent period that the architect had anything to do practically with clocks, since, although powerful instruments with large dials are frequently to be observed on Lombard and Romanesque campaniles in Italy, as at Cremona, Verona, the Palazzo Publico at Sienna, the turret of the townhall at Piacenza, the campaniles of Santa Prassede at Rome, and, indeed, in many Gothic towers as well, they invariably appear as subsequent additions and interpolations. The usual mode of adding the dial was simply to carry the main arbor of the clock through the wall, and either painting figures upon its surface or attaching a large metal ring to it, so as to make a level vertical frame corresponding with the orbit travelled by the extremity of the single hand showing the hours. As so added the clock dials rarely offend the eye, but where, as in the magnificent old campanile of Pistoia Cathedral, the whole of the lower part of the tower, which Giovanni Pisano intended to be in perfect repose, is disturbed by a great architectural frontispiece in stone or stucco, with heavy members surrounding and exaggerating the apparent anachronism, the effect is most objectionable. In speaking of the mediæval towers of his own country, M. Viollet le Duc makes the following observations on the apparent absence of provision for indicating the passage of time on the exterior of ecclesiastical structures: "On the towers of churches," he says, "from the twelfth to the fourteenth century, no space is arranged for dials which can be seen from a distance. This leads us to suppose that before the fifteenth century, if the chimes gave notice of the hours to the inhabitants of the towns there were no exterior dials. We do not meet with any until towards the end of the fifteenth century. They were then covered by small projecting roofs, and made either in wood or in lead, and decorated in colour." He (Mr. Wyatt) had not in any other country been able to find any deviation from what M. Viollet-le-Duc had observed with respect to France. One might, however, be misled occasionally where clock faces have been inserted into openings not originally intended for them, and be thereby induced to imagine that a clock occupies a setting intended for it by the architect of the structure. A good illustration of this occurs on the west front of Bayeux Cathedral, where the clock occupies what has apparently been the round window or rosace of a gable. In the same way he was somewhat uncertain about the clocks of St. Stephen's, Vienna, of the Freiburg steeple, and of the Townhall at Brussels. They may or may not have been intended to be placed where their dials now appear; but if either of them should have been so intended, it would be a decidedly exceptional case. Until better informed, Mr. Wyatt was inclined to believe that the architect's original connection with the clockmaker was limited to finding a chamber or safe depository for the clock, such as the Westminster clockhouse might be supposed to have been. Often this even might not have been necessary, as many clocks still retained their original positions, simply standing, as an organ might, as a piece of furniture in a church. The next stage was to connect the clock with the bells, so as to record time by striking upon them with a hammer. This naturally brought the clock into a chamber or a portion of the tower underneath the bells. Such appeared to have been the case at Exeter Cathedral in 1376-7, when costs were mentioned as having been incurred "for the room in the Northern tower newly to be made for the clock." At a later date, towards the end of the fifteenth century, they were found occupying the same relative position to the bells, but with the addition of external dials. Thus, at Prague, at the foot of the great tower of the old Townhall, there was a very remarkable clock with two large dials, one over the other, the lowest being raised but little higher from the ground than the height of a man, and the upper one being placed immediately above the lower one. These dials were inserted in stone frames elaborately carved, and of a structure apparently contemporaneous with that of the adjoining beautiful chapel, the date of which was about the middle of the fifteenth century. At a somewhat later date, at Basle, the dial of the Townhall clock was found to be regularly inserted in contemporary Third Pointed tracery. A more imposing example (now unfortunately destroyed) existed at Nuremburg, in the old Schau-Amt, or office of civic control, erected in 1522, opposite the Rathhaus. This clock turret was of very elegant Gothic design.* These were the most important examples Mr. Wyatt had been able to trace of the mediæval architect's practice in the incorporation of external dials into his architecture; but of the Renaissance architect's mode of dealing with the problem abundant illustration was afforded. The well known clock tower and clock of the Piazza of St. Mark's at Venice, erected in the year 1496, was amongst the most picturesque treatments of the subject. The clock chamber of the Château d'Anet, with its dials over the nymphs of Benvenuto Cellini, was very well designed, as, indeed, was the dial framework of the clock of the Palais de Justice of Paris. The interesting old *grosse horloge* of Rouen, in another style, was little less pleasing. The example of Italy was speedily taken up in the other countries of Europe, and she declined in the sixteenth and seventeenth centuries in the cultivation of the arts; the free cities of Germany, the Hanse Towns, and the great centres of Flemish and alternately of Dutch industry, took her place. Speedily the towers of hotels de ville and the leading old churches had clock dials added to them, but it was comparatively rare to treat them in any other way than as obvious additions and interpolations, and little or no effort was made by the architects to make them assimilate to the original architecture of the buildings to which they were added. As far as could be made out from early views of Nonsuch, the clock turret and dial were upon a large scale and of elaborate

* See an engraving from a drawing made by his uncle in Heideloff's "Ornamentik des Mittelalters."

design. It was probable, however, that the clock contained in the maoly campanile of Sir Thomas Gresham's original Bourse, christened the Royal Exchange by Queen Elizabeth in 1569, was by far the finest public clock in England at that date, since, judging by Hollar's accurate views, its dial must have been of very large dimensions so as to have been conspicuous at the great height at which it was raised above the ground. It was treated honestly, as it should be in a campanile, with a story to itself, with a balcony to allow a ready access to its face, and with a lofty belfry over to hold the carillons, which, no doubt, Sir Thomas had caused to be contrived in emulation of those then just introduced in Antwerp and other cities of the Low Countries. In the second Royal Exchange, reared by Jarman, the City Surveyor, immediately after the Great Fire, good accommodation was also provided for a clock, which was introduced as an elegant pavilion in the line of balustrading over the great window of the first story of the tower. When the campanile was rebuilt in 1821, in a style far beneath that adopted by Jarman, the modern architect showed himself quite incapable of appreciating either what the clock for such a structure should be or how to weld in his dials properly. He made it much too small, and then pinched it in on one of the octagonal faces of the base of his belfry between two boldly-projecting trusses, as though, ashamed of its poverty, he would fain do his best to hide it. In the present structure the clock turret is the portion of the building least pleasing. The accommodation provided was, however, good. As might be expected from an original member of the Royal Society, a profound mathematician, and an able mechanician,* good accommodation was not wanting in several of Sir Christopher Wren's principal churches for large clocks. Wherever he could, however, he avoided the architectural difficulties of the incorporation of the dials in his masonry. At St. Paul's the problem was evidently a difficulty to him, and his mode of dealing with it was not satisfactory. In the first place, his provision apparently for two clocks instead of one, for the sake of symmetry alone, was a mistake, and in the second, the prominence given to the curved form of the stonework over the dials disturbed the repose and apparent stability of that portion of the tower as a base for the belfry story. At St. Olave's, Jewry, he was more successful, making a distinct feature of the dressings to his clock dial, immediately under the belfry. In the same way the dial dressings of St. Bride's, Fleet-street, though very plain, are satisfactory. In the beautiful steeple of St. Mary le-Bow no provision was made in the structure for dial faces, but the design of the projecting beam and clock case was picturesque, sensible, and not unworthy of Wren. In Christ Church, Newgate-street, and St. Nicholas Cole Abbey, Fish-street-hill, the clock dressings were treated much as they are at St. Olave's, Jewry. In one or two other minor cases, as at St. Margaret Pattens, St. Clement's, Eastcheap, and St Mary Somerset, Thames-street, Wren appeared to have made provision for clocks which had not been supplied. In some cases, in which he seemed to have omitted any provision for clocks, and in which clocks had been subsequently added, anything but agreeable architectural effects had been produced. Thus in the church of St. James, Garlickhithe, the clock dials, surmounted by a quaint figure of St. James, were carried on a heavy beam, apparently poked out through the windows of the first-floor of the tower. The beautiful campanile of St. Magnus, London Bridge, was similarly disfigured. In St Lawrence, Jewry, a church with one of Wren's finest eastern ends, the tower was disfigured by dials with sham stone dressings, stuck, as it were, against each of the faces of the belfry windows. At St. Swithin's, London Stone, the dials formed a strange excrescence such as could never have been contemplated by Sir Christopher, flourishing out from one angle of the church with an evident desire apparently to fly away from it. The projecting beam and dials of St. Edmund's, Lombard-street, were equally an obvious afterthought. How far Wren may have been party to these somewhat bungling additions to his buildings cannot now be told with any certainty, since in exceptional cases only did the clocks themselves afford evidence on the point. Among Wren's immediate successors, Gibbs, perhaps, dealt with his clock dials better than any other architect. Those of St. Martin's-in-the-Fields, and of the new church in the Strand, were well-proportioned and conspicuous, without in any wise running counter to the forms or lines of the architecture. In Hawkesmoor's case, the St. Mary Woolnooth clock, the dials of which were carried out on a beam, was not in itself ugly or unpicturesque, but it was in nowise agreeably supported by or connected with the masonry of the structure. In more recent times still no great progress had been made, and in quasi Classical buildings, Mr. Wyatt could scarcely recollect an instance which speaking as an architect only, one would not have felt relieved if all external evidence of the existance of a clock could have been blotted out. He was strongly of opinion that this need not have been, and certainly for the future need not be. With the facilities for the use of external colour which were now brought within the architect's reach by the abundance of coloured glass, encaustic tiles, faience, and especially coloured enamels on large surfaces of iron, it was his fault, and nobody else's, if dials remained ugly or indistinct. With the ease with which he might now get a fair measure of stone or wood carving well executed, and ornamental terra cotta or metalwork supplied, he had no business to leave his clock faces without suitable dressings, or its aspect, as well as its going qualities, to chance or the clockmaker. All that was wanting was that he should bestow upon its design the same care and foresight he did upon other features of his building. If he ignored it at first, and was ultimately obliged to deal with it, he might rely upon its having its revenge for the neglect, and telling of his forgetfulness to the end of time. The architect should remember that his work should not be considered done when he had made a round hole in a wall to be filled up with a clock face, even in the best and most convenient situation, as had been done at the Horse Guards, and in a hundred other places. In whatever style he might be working, models were not wanting of circular panels or windows surrounded by most beautiful framework, borders, or tracery, and there was no reason why his clock dials should not be equally well cared for. There was no absolute limitation of the dial to the circular form; a square, an octagon, or any polygon in which a circle might be regularly inscribed, would do just as well as a circle for the bounding form of a clock dial, so that there was ample scope for the exercise of fancy on the part of the architect, who was certainly, in his treatment of turret clocks, far behind the industrial artists who had from the fifteenth century to the present time lavished all the resources of good art and perfect workmanship upon portable and house clocks generally. Much of this inattention to beauty in externals was to be associated with that kind of prejudice which held, if not theoretically at least practically, that science and art in their highest forms of development were incompatible, a form of prejudice somewhat countenanced by Mr. Denison's observation, "that the value of the inside of a clock generally varies inversely as the decoration of the outside." If this was true "more's the pity," since there was no reason why the ratio should not be direct instead of inverse, as it certainly was in the days when the workmen of Venice, Augsburg, and Nuremburg, and subsequently of Paris, led the trade. He (Mr. Wyatt) would remind them of that most beautiful design made by Holbein for the clock to be given by Sir Anthony Denny to Henry VIII. Had we any reason to doubt that the best work then to be procured would be put into that case? He might also remind Mr. Denison that the finest turret clock in the world, with the design of which his name must ever be honourably associated, was placed in the most beautiful clock tower, and had the most beautiful dials ever yet made for any clock of anything like the same dimensions and importance. Of course he (Mr. Wyatt) alluded to Westminster. One of the most novel modes of exhibiting time on a large scale, without interfering with simple architectural structure, was that suggested by Mr. Owen Jones for the central feature of the south elevation of the Exhibition of 1851, and ultimately carried out. At each of the intersections of the thirteen main radiating ribs of the semicircular face-work which formed the vertical end of the semi-cylindrical glass vaulting of the great transept, with the semicircular ribs embracing three 8ft. bays of the facework, Mr. Jones placed a figure, No. 12 occupying the highest intersection, and No. 6 each of the two intersections on the level of the horizontal chord of the semicircular arc. The hand or radius, 12ft. in length, starting at 6 on one side (representing 6 a.m.) rose, passing figures 7, 8, 9, &c. (a.m.), until it reached its highest point at noon, whence, like the sun, it descended through 1, 2, 3, &c. (p.m.), until it sank below its horizontal line at 6 p.m., only to rise and recommence its work the following morning at 6 a.m, having, in the interim, traversed a similar semicircular orbit. As a novelty this was fresh and suggestive, but owing to the number of lines radiating from the same centre as that from which the hand radiated it was difficult to recognise at a glance from any distance the correct position it occupied.*

[It appears that the condition of this society is even more flourishing than we described it in our article of last week, for inadvertently we gave its numbers as they were at the commencement of the session 1867-68, instead of the present session 1868-69. It appears that no less than 116 members joined during the past twelve months, so that taking into account the number of resignations, &c., the total at the opening meeting amounted to about 470.]

* Wren was a fellow-student with Huyghens of the law of impact, and, no doubt, of the theory of the pendulum also.

GLASGOW ARCHITECTURAL SOCIETY.

THIS society met on Monday evening, Campbell Douglas, Esq., I.A., the president, in the chair. A paper was read by Horatio K. Bromhead, Esq., I.A., on "the Antipathies of Architectural Grammar," in which the author sought to show how architectural ornament ought and ought not to be combined, and to lay down the following propositions:—

Proposition I.—The origin, continued existence, and increasing isolation of the various styles of architecture indicate the opinion of many ages as most remarkably decided in asserting that there are sympathies and antipathies among architectural forms and colours that a correct taste cannot ignore, and that there are varied wants and requirements that have demanded and maintained a variety of style.

II.—An architectural work should not have a single detail of form or colour that is not in harmony with every other detail, and with the use and situation of the work, but should be treated as a harmonious whole.

III.—A new discovery, feature of design, method of construction or colouring, material for execution, or locality for erection has often caused a transition time of modification, finally resulting in the rejection of a previous feature and the production of a different style of architecture that avoids the discords occasioned by the novelty. Transitional styles are therefore of confused and imperfectly developed grammar; and a combination of styles containing unmodified parts of two or more distinct styles is flatly discordant and ungrammatical, and much to be condemned as a violation of æsthetics.

IV.—Architectural features, when used in several styles, though retaining the same name and skeleton, should not be so used without being modified in detail and outer form, so as to possess a sympathetic character for each style. The principles and methods of colouring should also be subject to this proposition.

V.—If a well known feature or detail that is to be found in many buildings is very seldom to be found in the same building with another well known style, feature, or detail, without modification, the combination without the customary modification is a discord that requires marked and careful sympathetic modification to become grammatical.

After some few closing remarks Mr. Bromhead concluded his reading, which was very well received by the meeting.

SKETCH FROM THE CHOIR, SELBY ABBEY.

WE give this week a sketch of one bay of the choir of Selby Abbey. Our readers will remember that the large abbey church of Selby is on a cathedral scale. The nave is Norman, and the choir was built at that period which is usually considered to be the zenith of our mediæval architecture; and perhaps it would be difficult, amongst all our cathedrals, to select anything more beautiful for correctness of proportion and delicacy of detail than this part of Selby. The foliated caps and canopies are very much choked up with whitewash; but enough is visible to show that they are fine specimens of the full and rich detail of the period.

* To be continued.

THE SPACE FOR ARCHITECTURAL DRAWINGS IN THE NEW ROYAL ACADEMY.

IT has, we learn, been officially announced to the Council of the Royal Institute of Architects that the new exhibition rooms of the Royal Academy will be completed and opened for the reception of works next March; and this intimation has been accompanied by a gratifying assurance to the profession that their works will no longer be condemned to be crowded into a mere passage room as hitherto. There are there, it appears, no less than fourteen galleries, at least 41ft. by 31ft., all of which are equal in point of light and position, so that architects may rely on justice being done to their productions in future. It is hoped, therefore, that architecture will be well represented on the occasion of the opening of the new Royal Academy. How far these new facilities may operate upon the prospects of the ensuing Architectural Association we cannot venture to predict; it is obvious, however, that there will be still a large class of the more practical and not the least useful descriptions of drawings for which admission to these new galleries can hardly be expected or desired, so that, doubtless, the energetic committee of that Institution will find the necessity for their labours will not be superseded. If, therefore, they lose some of the more attractive of the perspective views of buildings, which their authors will doubtless prefer to send to Burlington House, they must seek to develope that kind of careful and purely architectural delineation of designs which was so well represented by the splendid drawings sent by Mons. La Meire to the last Architectural Exhibition. Should they succeed in so doing we venture to anticipate that architecture will gain even by the separation of the two classes of drawings, for by the indiscriminate mingling of them it has often been felt that both have suffered.

IMITATION IN REFERENCE TO THE STYLE OF ECCLESIASTICAL BUILDINGS.

A FIERCE contest is going on about the reproduction of ancient styles and the propriety of abandoning anachronisms for a new style of the day. It is said that when some time hence London shall be as Nineveh, and the antiquary comes here to examine its relics, he will say such an edifice appears to be of William Rufus, such a one of Edward I., and at length he will find inscriptions or other evidence certifying the building to be of this day of Queen Victoria, and he will be much horrified at having been so deceived and at the want of truthfulness in the art of this century. All will pity much this archæologist, whether he come from Lake Nyanza or the Kara Korum range to improve his mind and instruct the future generations of a thousand years hence, and yet with all this sympathy we doubt whether any one of this present day will abstain from gratifying himself to ensure the gratification of the virtuoso of posterity, or whether, as we are so callous to the enlightened criticisms of competent men of our own country and the continent, we shall be sufficiently heedful of the criticism of those we know nothing about, and whose existence hereafter is highly problematical, should they find anything to exercise a judgment upon. Before the verdict of the coming time can be given, already will most of the works that are obnoxious to judgment have passed into ruin and oblivion, and some of the very worst examples will become the earliest victims.

We are apt to be too careful of futurity, and to assume for our works too great a durability, whereas the life of architecture is by no means assured even in the case of its best examples. This is well enough seen if we make an enumeration of the best temples of Greece or the best edifices of Rome. Of some of these we have relics, but of some we are so deficient as to be utterly unable to reconstruct the plan or outline. Even in the case of a monumental work this is so, for the life of any such building is exposed to vicissitudes, fire, earthquakes, war, change of religion, and so many incidents of casualty. Other smaller buildings are liable to removal because the site is wanted for other purposes. The same influences prevail in our days, and no architect can be assured that his works will be preserved. There was the old Treasury, in Whitehall; Sir John Soane refaced that, and Barry effaced Sir John Soane, and now Barry is doomed to give way to a Palace of Government. Then Sir John Soane laboured on the College of Surgeons, again to be encountered by Barry, and within a very brief period Sir John Soane's law courts at Westminster will be demolished by the younger Barry. There is Burlington House now being moved stone by stone; and who can tell what will be done with the National Gallery, or even the Post Office, for an adjunct to the latter is arising on the other side of St. Martin's Le Grand, which may be connected? No one would have dreamed of the wholesale destruction of Wren's buildings consequent on the removal of the City churches, and thus this prolific architect is threatened with the diminution of his monuments.

While the casualties of time very much reduce the value of what may be called the life assurance of a building, it is open to question, after making a good allowance for artistic qualifications, whether its utility is not one main characteristic after all in a short life or a long life. There are many circumstances indeed which tend to limit the pre-eminent consideration of style besides utilitarianism. Conventionality is one of these, particularly in reference to ecclesiastical architecture. In respect to this department there has certainly been a dominance of style. The reason we have Roman styles in their present state must be traced to the effect of Greek influence on the worship of Rome—an influence altogether apart from the literary influence, which may be considered of later date. The conventional idea of a Greek temple passed into Roman traditions, although there was a great difference in the local relations of a small Greek sovereign city and those of the Roman metropolis or of a Roman colony.

The same influences are to be defined in Egypt, acting even down to a later date, when first Greek modifications were adopted and afterwards Roman. So, too, with regard to Assyrian, Buddhist, or whatever class of worship we may refer to. This is assuredly less a matter of nationality or chronology than of religious faith. We see it strongly in the case of Mussulman structures, for, notwithstanding the various nationalities which have adopted the Mahomedan faith, we trace resemblances throughout. The divisions of race are great: the Arab is a Semite, the Persian an Indo-European, the Turk a Turanian. The architecture of Constantinople is anomalous in every respect. Santa Sophia is a Byzantine structure converted into a mosque, and yet is made to bear a nearer relationship to Cairo and Assyrian than to Christian or Grecian art. The consistency that it claimed is very questionable in most instances, and where it obtains it may, in reference to the general history of art, be considered as exceptional.

Traditions of art particularly affect religious edifices. The form and structure of churches in this country are the development of what is regarded by the high vulgar and the low as the suitable style for such buildings. Notwithstanding all that has been done from the time of Wren in Italian, and the Georgian outburst for Classic, the Classic and Italian styles have not been able to keep their ground or suppress their mediæval rivals. A natural example of reverence for tradition in art is to be found in the Greek church in London Wall. The congregation naturally preferred Byzantine, and such is the style adopted. They would have felt themselves schismatics in another structure.

One question is how far it is legitimate to comply with these popular conventionalities, and another is as to the practicability of our inventing anything which may serve as a new substitute and make the Victorian era better than the Caroline or Georgian era have been marked. Whether rightly or wrongly we shall experience mediæval influences in ecclesiastical architecture, and we have yet to learn what modification of it we can successfully accomplish.

REREDOS, CHRIST CHURCH, BRADFORD, NEAR MANCHESTER.

THE reredos which has just been completed is executed in Caen stone, relieved with polished shafts of Devonshire and Derbyshire granite. The principal features are the three gablets, the middle one containing a carved panel with the words, "Do this in remembrance of Me," and the emblems of the four Evangelists, and the other two contain respectively carved panels with the words "I am the Bread of Life," and "I am the True Vine." The panels at the side contain the Commandments. The whole has been executed by Messrs. Williams, sculptors, of Manchester, from the designs of Mr. John Lowe, architect, of Manchester.

SCHOOL OF ART.

On Tuesday week, the annual meeting of the Newcastle-under-Lyme school of art took place. The report stated that, although a financial deficit of £30 existed, yet the year past had witnessed great improvement, both in the subscription list and the general condition of the school. The report of the head master (Mr. J. R. Bacon) showed that out of the drawings which were finished in the school during the previous twelve months and sent to London in April to be examined, the works of ten students were satisfactory, three obtained prizes, and one honourable mention. At the National competition, at which about 100 schools compete for 10 gold, 20 silver, and 30 bronze medals, one bronze medal was awarded to this school. Two of the students, viz., W. P. Rhodes and F. J. Watkin, have been appointed free students, the Science and Art Department paying their fees for twelve months. The reports were adopted, and the prizes then distributed. It is believed that the deficit of £30, before alluded to, will be speedily cleared off.

ARCHÆOLOGY.

An antiquarian discovery has just been made in Hanover. Some soldiers, in digging a trench at Hildesheim, found about 50 vases, cups, candelabras, and other objects in massive silver, and richly chased; they are evidently the work of the Greek artists, and apparently date from the time of Augustus. Among them is a goblet, with ornaments in relief, representing Hercules strangling two serpents; and a second, with satyrs, bacchantes, and other similar figures.

Building Intelligence.

CHURCHES AND CHAPELS.

Ambrosden Church, Bicester, which has been undergoing a thorough and substantial repair, was reopened on Tuesday week. The restoration of the church has been ably carried out by Mr. C. N. Beazley, of Guildford-street, London, and the work has been executed by Mr. Lewis, of Bicester. The church consists of a spacious nave and south aisle, and a chancel of fine proportions; the latter being a good specimen of the Perpendicular style of architecture. The tower, originally Norman, has buttresses and parapet of the Perpendicular period; and the nave, originally of the Middle Pointed style, has a clerestory of the fifteenth century. The cost of the restoration is £1,400.

On the 7th inst. the memorial stone of a new Wesleyan Methodist Chapel was laid at Westhoughton, by Mr. J. Bell. Mr. George Woodhouse, architect, of Bolton, has designed the chapel, which is of a very plain character, and built of concrete, moulded by the patent apparatus of Mr. Charles Drake, of London, under the immediate superintendence of Mr. John Drake, and will be plastered over with stucco, lined to imitate stone. The entrance will be by a porch beneath a tower 15ft. high. The chapel is expected to seat about 300 persons, and a gallery will provide accommodation for an additional hundred, including the school children and the choir. The entire cost of the building is about £850.

Yesterday week a new Congregational Chapel was opened at Blyth near Newcastle-on-Tyne. The style is Gothic, of an early type, and the materials used are red bricks with chiselled stone dressings. The plan consists of nave and transepts, with galleries at each end. The cost is about £1,700, and the chapel seats 500 persons. Mr. T. Robson, of Newcastle, is the architect, and Mr. J. Nairn, of Blyth, the builder.

A new Wesleyan Chapel was opened at Pilsley on Tuesday week. The style is Gothic, of the early part of the fourteenth century, and it is built of clean pressed bricks with local stone dressings. Two schoolrooms are attached, available as transepts during service. The cost is £750, exclusive of fencing, walls, and cartage. Mr. S. Rollinson, of Chesterfield, is the architect, and Mr. G. Heath, of the same place, the builder.

The monthly meetings of the Incorporated Society for Promoting the Enlargement, Building, and Repairing of Churches and Chapels for the present session were resumed on Monday at the society's house, No. 7, Whitehall, S.W.: the Right Hon. the Earl of Romney in the chair. Grants of money, amounting to £855, were made in aid of the following objects, viz.:—Building the new church of St. Matthias, Earl's court, Kensington; rebuilding on a new site the church at Mistley, near Manningtree, Essex; enlarging or otherwise increasing the accommodation in the churches at Birstall, near Leicester; Bishop Stortford, Herts; Bradfield Combust, near Bury St Edmund's; Brede, near Northiam, Sussex; Bucknell, near Shrewsbury; Burrington, near Chumleigh, Devon; Discord, near Presteign, Radnor; Hellingley, near Hurst Green, Sussex; Llanbedr Paincastle, near Hay, Brecon; Llanfwrog, near Ruthin; Llanbadarn Fawr, near Aberystwith; Marlborough, near Kingsbridge, Devon; Mordiford, near Hereford; Quainton, near Winslow, Bucks; and Terrington, near York. Additional aid was voted towards building the churches at Fylingdales, near Whitby, and Traveller's Rest, near Barnstaple; rebuilding the church at Weston Patrick, near Odiham, Hants; enlarging and restoring the churches at Eaton Socon, near St. Neots; St. Lawrence, Reading; Shadoshurst, near Ashford, Kent; St. Margaret's-at-Cliffe, near Devon, and Sutton, near Rochford, Essex. The society likewise accepted the following trusts as repair funds for Halliwell St. Peter, near Manchester; Eastover Christ Church, near Bridgewater; St Stephen, North Meals, Chester; for a consecrated mortuary chapel, Cambridge, and a legacy of £1,000 bequeathed by a lady for the restoration of the church at Ramsden Crays, near Billericay, Essex.

BUILDINGS.

At a meeting of the Halifax Board of Guardians on Wednesday week, the various tenders for the enlargement and alteration of the Halifax workhouse were submitted, and that of Mr. Jonathan Charnock, of Hall-street, Halifax, accepted. The amount specified is £6,845, and his contract includes the stone, brick, joiner, carpenter, slating, plastering, plumbing, glazing, and painting works required. The operations are forthwith to be commenced, and to be completed by September 1, 1869. Additional land has been purchased for the site, and the plans for the alterations have been prepared by Mr. Oates, architect, Halifax, who was yesterday week appointed the superintendent of the works. The new buildings will be mostly for hospital use, on the pavilion plan, separate buildings for males and females, each three stories high and 100ft. long, all the wards being lofty and 22ft. wide. Distinct hospitals for males and females, each containing four spacious wards, will be erected for fever and infectious cases. Then there will be day rooms, dormitories, bath rooms, nurses' rooms, lavatories, &c., arranged on the most efficient plans, and in accordance with the instructions of the Poor Law Board. It is likewise intended to erect new kitchens, to be fitted with the most modern appliances for cooking, &c. The total cost will probably reach nearly £ 0,000.

The opening meeting of the session of the Royal Institute of the Architects of Ireland was held last evening at eight o'clock to receive the annual report of outgoing council, and treasurer's statement of receipts and expenditure, and to elect officers and council for the ensuing session. The silver and bronze medals awarded by the council at the close of last session were to Mr. Samuel P. Close, associate, and Mr. William Sterling, fellow, respectively.

TO CORRESPONDENTS.

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

RECEIVED.—W. Stone Co.—C. G.—E. and Co.—W. M.—J. P.—C. T.—J. H.—S. W. and Co.—H. C.—W. S.—W. W.—H. D.—M. G.—J. P. S.—F. C.—I. C.—W. I. C.—I. H.—H. C.—W. S.—"Clerk."

PATENT.—It will all depend on the nature of the improvements you have made.

ERRATUM.—In article in last week's number, on "St. Paul's, Past and Present," on page 779, top of column 3, read "and *not* art had accomplished the work;" for "and art had accomplished the work."

Correspondence.

"ROOF COVERINGS AND EXTERNAL DESIGN."

To the Editor of the BUILDING NEWS.

SIR,—With your kind permission I will make a few observations on an article under the above heading which appeared in your last issue:—

The writer there remarks, that "*green slates* have a doubtful reputation for durability." I readily admit that some kinds of slate are porous and non-durable, but when reading the article in question, it struck me that your correspondent probably had not seen at "the Museum of Building Appliances" (9, Condnit-street), a specimen of olive green slate, of "Gane's eureka tint," a slate that unquestionably possesses all the requisite properties for *strength* and *durability*. These slates (which are made in regular sizes) are *stout*, and show the edges much more distinctly than the ordinary slate, the thick raised edges showing (especially where small sizes are used) *strongly defined lines*, which add so much to the beauty of a roof.

Fifteen years' experience in various kinds of roofing convinces me that these slates are among the very best coverings for buildings we have—not only for durability and strength, but for effective appearance; and I think that, if your correspondent of last week will inspect the slate referred to, he will find its texture *close* and *hard*, in contra distinction to the porous slate frequently used. Apologising for thus troubling you, I am, &c.,

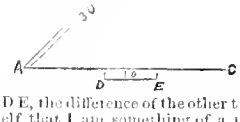
ANTI-TILE.

Intercommunication.

QUESTIONS.

[1128.]—CALCULATION OF PRIME COST.—Will any of your building friends favour me with the subjoined information? I have a house to build, the estimate for which is £600, and shall require to know on closing my books what I shall gain or lose by the undertaking. The materials I shall purchase and the labour I shall pay for will cost various prices, and some of it will be sent to customers at my usual day charges. Should the material and labour supplied to the house be placed through my books at the selling price? and is my gain or loss constituted by the difference between the selling price and the estimate? or, if not, how should I calculate it, when it is evident that the prime cost cannot be got at only by a distant approximation?—HENRY W. BADGER.

[1129.]—TRIANGLES.—Could any correspondent inform me whether it is possible to solve the following problem?—Given A B, one side of a triangle, = 30°: the angle, B A C,



= 40°; and D E, the difference of the other two sides, = 10°. I flatter myself that I am something of a mathematician, but I have not been able to solve it.—R. F.

[1130.]—CEMENT RECIPE WANTED.—Would you kindly inform me, through "Intercommunication," of a good substance that will make India rubber and wood stick well together when exposed to the wet? and oblige—A CARPENTER.

[1131.]—FRESCO PLASTER.—Will any of your readers kindly inform me of the materials of which the plaster for fresco painting is composed, and if the ordinary painters' dry colours are proper to use for the purpose.—A. O. F.

[1132.]—REMOVING WHITEWASH.—I want an efficient process for removing coats of whitewash from old stonework, plain and moulded, without injuring the face of the stone.—A. O. F.

[1133.]—CHIMNEYS.—The owner of a spot of land adjoining my house has lately erected a residence thereon, and has built the end wall abutting and considerably higher than my chimneys. The effect of this is to obstruct the free passage of smoke, which I have enjoyed upwards of fifty years, and renders it impossible for me to have a fire, which at this season of the year is exceedingly inconvenient. Will any of your readers be kind enough to tell me if I have a remedy against my neighbour? and I should be glad to know of any similar cases which have had judicial judgment.—B. W. R.

[1134.]—LATEST PRICES OF MATERIALS USED IN CONSTRUCTION.—Will some one kindly inform me, through "Intercommunication," where I can buy deals at the prices quoted in the BUILDING NEWS? and oblige—A YOUNG BUILDER.

[1135.]—QUESTION IN STATICS.—Suppose an uniform heavy rod, 5ft. long, is placed in a hemispherical bowl (unfixed) of 4ft diameter, in what position will it rest? I have been told that the above problem admits of an easy solution, but I am not able to work it out. Could any ingenious reader help me out of my difficulty?—RODNEY.

[1136.]—PUPILS' ARTICLES.—I have been in the office of an architect and surveyor (holding a public appointment and of moderate private practice) as clerk for about four years, but seeing the advantage obtained in after life by having passed through articles, I am desirous of doing so under the gentleman with whom I am at present serving. He has rather an objection to receiving pupils, as a rule; but having known me for a long period he would make an exception in my case, and has left me to tender a statement of what terms, &c., I would propose. I have attained a tolerably accurate knowledge of the profession generally, both outdoor and office work, and am in receipt of a salary of £100 per annum; aged 20. Under these circumstances, I am anxious to know what would be fair terms to both on the following heads: Duration of articles; amount of premium, and whether returnable as salary; and any other points which perhaps some of your many subscribers could suggest, if you would kindly make the case known in the way I have mentioned.—CLERK.

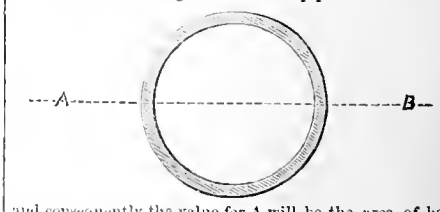
REPLIES.

[1091.]—ANCIENT WRITING MATERIALS.—One of the most ancient methods of recording events in writing was by the use of the "stylus" and brazen tablets. The former was a kind of metallic pencil, pointed at one extremity with steel, and blunted at the other. The tablets were merely thin sheets of brass, upon which were written by the sharp end of the "stylus" whatever was required. The blunted extremity was for the purpose of rubbing out or erasing any erroneous mark or letters. Our word paper is derived from the Latin term for a certain description of broad-leaved plants "papyrus," which was subsequently used as a medium for writing on. The bark of trees was a favourite "paper" among savage nations. When the Spaniards conquered Peru, the news of their invasion was carried into the interior, not by writing, but by drawing a description of their appearance upon leaves and the bark of trees. In the same manner the Indian chiefs describe what is termed their "totem."—HAYLEY.

[1092.]—LIQUID INDIAN INK.—I have heard it stated that a little vinegar mixed with Indian ink will keep it moist, but I cannot say I ever tried the experiment, so that "T. E. B." must take the statement for what it is worth. Every draughtsman is well aware of the trouble and annoyance caused by the fact that ink will dry up. The only real remedy is to bear with it. Never mind the trouble, but mix your ink fresh every day you use it. It is the only safe plan if you have to wash your drawing over with colour.—S. S. P.

[1092.] In reply to "T. E. B." on the above subject in the BUILDING NEWS of October 30, I have found by experience that the best way to preserve Indian ink in a liquid state without evaporation is as follows:—Having rubbed sufficient Indian ink to complete the work in hand in an ordinary colour saucer let "T. E. B." place the same in a deep plate or other vessel containing a small quantity of water, then over the ink saucer invert a glass tumbler so that its edge shall rest in the water. "T. E. B." will readily understand the principle of the above. Indian ink can in this way be preserved from evaporation for weeks and even months.—A. E. PEARSON.

[1093.]—IRON PIPES.—Your correspondent "Alpha" may calculate the strength of his pipe by the usual formula—$W = \frac{A \times D \times C}{L}$; bearing in mind that the neutral line A B in the figure divides the pipe into two halves,



and consequently the value for A will be the area of half the mean circumference of the pipe multiplied by the thickness. All the dimensions will be in inches, and the value of C for cast iron is equal to 25.—BETA.

[1096.]—STIFFNESS OF BEAMS.—Upon the authority of Tredgold, Molesworth, in his excellent little pocket-book, gives the following rule for the stiffness of beams:—Let B = breadth of beam in inches; D = depth, also in inches; L = length in feet; and W = load in pounds. Putting C for the constant, we have $D = \frac{\sqrt[3]{L^2 \times W \times C}}{B}$. The values of the constant C are as follows, for the different timbers:—Fir = 0.01; ash = 0.01; beech = 0.013; teak = 0.008; elm = 0.015; mahogany = 0.02; oak = 0.013. When the beam is uniformly loaded, instead of W use W × 0.625.—ARCHITECT.

[1098.]—SIZE OF BOLTS.—Having erected pillars in a position similar to that mentioned by "Contractor," I am in a position to inform him that bolts 2in. in diameter will answer perfectly well. I would advise him to have lugs cast upon the pillars to receive the nuts of the bolts, and to use cast iron bed plates, instead of a strap, underneath the concrete.—ENGINEER.

[1100.]—A WASH TO CONFINE SANDSTONE.—Let "W. H. Fowles" give his walls a good double coat of paint, and he will find they will soon cease to give off any dust.—T. E.

[1104.]—APPRAISER'S LICENCE.—There is no question but that you must take out a licence. The difference between you and a clerk is, that the latter performs his duties for his master, and is for the time being his representative and proxy. The master has a licence, and since you are now in that position you must protect yourself in a similar manner.—CLERK.

[1105.]—CENTRIFUGAL FORCE.—The angular velocity may be thus calculated:—Let W equal the weight of the body in pounds; R = radius in feet, or distance from the centre of motion; F = centrifugal force or angular velocity in pounds; N = number of revolutions in a minute; then $F = W \times R \times N^2$. This is sufficiently accurate for practical purposes, although not the exact theoretical formula.—ARITHMETICIAN.

[1109.]—LAND SURVEYORS' CHARGES.—In reply to "X.," I beg to inform him the general practice is an agreed sum for the survey and plan, either in the lump or as per acre. This, of course, would depend upon the position of the land, and whether contained within a ring fence or in detached pieces. If a moderately open country, and lying altogether, 5s. an acre, or £5 the whole, would be a fair charge for survey and plan showing proposed roads and building plots. For after management, a percentage upon the sales effected is the usual course, and varies from 2½ to 5 per cent. If land is sold to speculative builders, and advances made as the buildings progress, it is usual to charge an additional fee for each certificate granted. "X." would also require levels taken and sections of the proposed roads made.—H. H. H., Liverpool.

[1119.]—MEASUREMENT OF BRICKWORK.—Your correspondent, who signs himself "B B.," can prove the correctness of his own measurement with that of the other surveyor by multiplyiog his number of statute rods by 11½, which result will reduce his rods to cubic yards, there being 306 cubic feet, or 11½ cubic yards, to one rod of reduced brickwork.—ARCHITECT, Strand.

[1119.]—In reply to the question propounded by "B. B.," in your impression of the 13th inst., about comparing the results of measurements of brickwork in cubic yards with those in statute rods, I offer for his perusal the following: 11½ cubic yards, or 306 cubic feet of brickwork equal one standard rod; or, if "B. B." reduces the other surveyor's results to cubic feet, and takes 8-9ths of this sum, he will obtain the standard of thickness. Example: Suppose 230 cubic yards—

(1) 230 cub. yds. ÷ 11½ = $230 \times \frac{3}{34} = \frac{690}{34} = 20\,5\text{-}17$ st. rods.

By (2)

230 cub. yds.			
27		9)49680	
		272) 5520(20 5 17	st rods,
1610		544	[same as
460			[above.
6210 cub ft. × 8 ÷ 9		80	
8		$\frac{80}{272} = 5\text{-}17.$	
49,680			

MARTIN B.

[1119.]—"B B." can compare the results by multiplying his measurement, which is in standard rods, by 11.37, which will reduce his to cube yards.—C. D

[1119.]—If "B. B." will take the trouble to look in "Laxton's Price-book," he will find the number of cubic yards in a statute rod of brickwork to be 11½. "B. B" will do well to consult "Laxton" a little more before attempting to measure up work after another surveyor, and not fill up your valuable columns with so simple a question. Or he might have found it for himself if he had multiplied 272, the number of superficial feet in a rod of brickwork, by its thickness, 1ft. 1 in., giving 306 cubic ft. = 11½ yds. cubic.—D.

[1119.]—As there are four times the quantity of brickwork in a yard cube that there is in a rod of 8ft. superficial by 9in. thick, so let "B. B" multiply the cubical quantity by 4, and the answer is in rods. Proof: Suppose a wall 30ft. by 15ft. 9in. thick = 50 rods superficial = 12½ yards cube. Then 12½ by 4 = 50. I admit, however, that this is taking it to a great nicety.—H.

[1119.]—To reduce cubic yards of brickwork to feet superficial, 14in. thick, multiply by 36 and deduct one fourth; or multiply by 27 and deduct one-ninth.—J. K.

[1120.]—FALLING BODIES.—In answer to "Student"—1st. It has been ascertained by experiments that a dense or compact body when falling freely passes through the space of 16ft. 1in. during the first second of time. For example: Suppose a dense body falls 144ft.; divide the number by 16ft. (leaving out the odd inch for the sake of even numbers), which will give 9, then extract the cube root = 3 = the number of seconds in falling, as near as possible. 2nd. A light body will fall with the same velocity as a heavy one, provided it is of the same material and quality. If the atmosphere were removed all bodies, light or heavy, large or small, would descend with the same velocity. For instance, when a piece of coin and a feather, or any other light substance, are let fall at the same time from the top of the exhausted receiver of an airpump, they would fall at the same rate, and touch the bottom together. 3rd. In answer to queries 3 and 4, all bodies in descending continue to increase their velocity, as the attractive quality of the earth increases as the distance decreases. No positive rule can be given as to the increase of velocity in the descent of bodies on account of the changes which take place in the atmosphere, which renders the resistance variable.—G. W., Tonbridge.

[1120.]—If "Student" had consulted the most elementary treatise on dynamics, or bodies in motion, he would have found the rule for calculating the rate at which bodies descend from a fixed point. I give it under, condensed as much as possible, so as not to trespass on your space.

1. Space.—The space described in a certain time is equal to the product of the square of that time and the space fallen through in one second (16·0 ft., in the latitude of London); or, if the velocity and time are given, it is equal to one half the product of the velocity and time; or, if the velocity only be given, it is equal to the square of that velocity divided by twice the velocity acquired in falling one second (32·19ft.).

2. Time. The time of falling is equal to the velocity divided by twice the space fallen in one second; or it is equal to twice the space divided by the velocity, or it is equal to the square root of twice the space divided by the velocity acquired by falling one second.

3. Velocity.—The velocity is equal to the velocity acquired by falling one second multiplied by the time of falling; or is equal to twice the space divided by the time, or it is equal to the square root of the product of twice the space and the velocity acquired by falling for one second. Putting s for space, t for time, and v for velocity, we have:—

1 $s = 16.09\,t^2 = \frac{1}{2}\,t\,v = \frac{v^2}{2 \times 32.19} = \frac{v^2}{64.38}$

2 $t = \frac{v}{2 \times 16.09} = \frac{v}{32.19} = \frac{2\,s}{v} = \sqrt{\frac{2\,s}{32.19}}$

3 $v = 32.19\,t = \frac{2\,s}{t} = \sqrt{2 \times s \times 32.19} = \sqrt{64.38\,s}$.

I do not carry the decimals any further, as they are quite true enough for all practical purposes.—MARTIN B.

[1120.]—"Student" will be able to solve all questions relating to falling bodies by means of the following formulæ:—

$$v = g\,t + v^1 \quad (1)$$

$$s = \frac{g\,t^2}{2} + v\,t \quad (2)$$

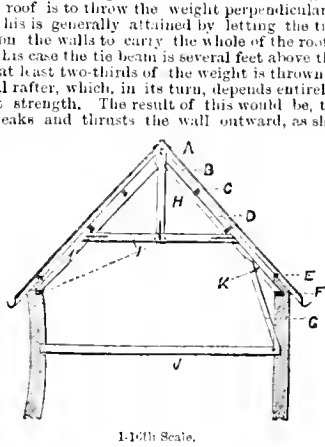
$$v^2 - v^{1^2} = 2\,g\,s \quad (3)$$

$$v^{1^2} - v^2 = 2\,g\,s \quad (4).$$

Where v = velocity in feet per second, v^1 = the initial velocity, t = time in seconds, s = space described, g = measure of the force of gravity, which is the velocity acquired by a body falling freely from a state of rest in a vacuum in one second, and which is taken in the latitude of London at the sea level, = 32·2ft. If the body is acted on by gravity alone $v^1 = 0$ in these equations; if projected downwards, with an initial velocity, v^1 = positive; if upwards, negative; 3 and 4 are simply deduced from 1 and 2, and are used according as the body is projected downwards or upwards with an initial velocity. If the resistance of the air be removed, all bodies under the action of gravity would fall through the same space in the same time, consequently gravity accelerates all bodies equally.—C. D

[Similar answers have been received from "J. B. P., Aberdeen," and "W. J. Dray."—ED. B. N.]

[1122.]—ROOF CONSTRUCTION.—I have ventured to send you a sketch showing the construction of a roof that has puzzled "A Beginner." The tendency of every roof is to sink down into the rooms below, or the pressure of the walls outward; and this is caused by its own weight and the pressure of wind acting on one of its sides. The great aim in every roof is to throw the weight perpendicular on the wall. This is generally attained by letting the tie beam resting on the walls to carry the whole of the roof above. But in this case the tie beam is several feet above the wall, so that at least two-thirds of the weight is thrown on the principal rafter, which, in its turn, depends entirely on its inherent strength. The result of this would be, that the rafter breaks and thrusts the wall outward, as shown in

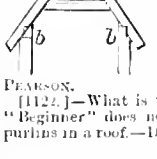


1-16th Scale.

A, Ridge, 7in. by 1½in. B, Rafter, 3in. by 2in. C, Purlins, 8in. by 4in. D, Principal Rafters, 7in. by 3in. E, Wall plate, 4½in. by 3in. F, Pad, 9in. by 2in., 2ft. long. G, Strut, 7in. by 3in. H, King Post, 4in. by 3in. I, Tie beam, 7in. by 3in. J, Joist. K, Strap.

left-hand side of sketch. An iron rod, as dotted, would, in a measure, counteract this; but this, in its turn, being subject to extreme variations of temperature, would expand and contract. I have, therefore, suggested a strut, tenoned into joists, and supporting the principal rafter at the point of its liable deflection, and thus making the joists do duty as a tie beam, and throwing the whole weight dead on the walls. Common rafters and purlins are subject to cross strain; in the figured dimensions I have made the former small, because the bearing is little, but the sizes of purlins must be arranged according to the length of bearing; the figures named would be safe for 8ft. Principal rafters are subject to cross strain and compression; strut to compression only; king post and tie beam to tension.—H.

[1122.]—In answer to "A Beginner," in the BUILDING NEWS of November 13, the collar would be in a state of tension, as the thrust of the principals is outward. Purlins are necessary, and should be placed as in the subjoined sketch or a purlins h h plates). The purlins should be 7in. by 4in., plates 4in. by 3in. There is no necessity for joining the collars at the intersection of the roofs.—A. E. PEARSON.



[1122.]—What is the length of the proposed building? "Beginner" does not exactly understand the use of the purlins in a roof.—D. Y.

[1123.]—WAR DEPARTMENT CLERK OF WORKS.—In your "Intercommunication" column of the 13th inst., a "Constant Subscriber" wishes to know how to obtain an appointment as clerk of works to the War Department. The writer of this reply, as holding that situation himself, can, from his personal experience, inform your correspondent that no fresh appointments have been made for eight or nine years, and that it is also generally understood that the civil branch of the Royal Engineer Department are to be allowed gradually to disappear. There have been many temporary clerks of works employed on various large works, but their services are liable to be discontinued at any time.—FIFER.

[1126.]—CIRCULAR GAS TANK.—Reservoirs at Penbridge, near Tunbridge, have been successfully lined with Pyrimont asphalte, to avoid the escape of water. Why not line your gas tank in the same manner? It seems impossible, from the description of a work so well done as yours appears to be, to account for the great escape of water from the tank.—J. J.

BUILDING AND LAND SOCIETIES.

AT a meeting of the members of the insolvent Victoria Land and Building Society held in Birmingham on Wednesday week, an offer by the directors to pay £7,500 in release of all claims against them was unanimously accepted.

WAGES MOVEMENT.

THE Bolton Branch of the General Builders' Association has issued to the Bolton Operative Stonemasons' Society a circular notifying the following alterations of rules, to come into force on May 1, 1869:—1. The rules relating to reckoning of time, and quarter time, and payment of wages, are to be abrogated and rescinded, and in lieu thereof wages will be paid at the rate of 7½d. per hour. 2. Any rule or custom forbidding or interfering with the employment or use of machinery or machine worked materials is to be abrogated and entirely done away with. 3. Any rule or custom forbidding or interfering with the introduction or use of stone worked at the quarry, or anywhere else than the place where it is to be used, is to be abolished and done away with. 4. That all trade rules, disputes, demands, and differences shall be settled for the future by consultation or arbitration, and proper courts shall be constituted for the purpose. The masters further state that they are prepared at any time, upon six days' notice from the men, to meet them and appoint arbitrators, and select the umpire. And they are willing to leave to the decision of the arbitration court thus appointed, all future settlement of trade rules and disputes, demands, and differences. Circulars to the same purport (as far as the wording is applicable) have also been forwarded to the joiners, painters, plasterers, and plumbers in this town.

The Wakefield Branch of the General Builders' Association has issued a notice to the operatives of the trade, notifying that on and after May 1 next, the rules relating to the reckoning of time and quarter time and the payment of wages are to be abrogated and rescinded, and in lieu thereof to be calculated and paid for by the hour, and that all trade rules, disputes, demands, and differences shall be settled for the future by consultation or arbitration, and proper courts shall be constituted for that purpose. The masters are prepared at any time, after six days' notice from the men, to meet them and appoint arbitrators and umpire. And they are willing to leave to the decision of the arbitration court thus appointed, all future settlement of trade rules, disputes, demands, and differences.

The stonemasons and labourers in the building trade of Wolverhampton have had notices given by the masters as to a proposed alteration of rules. The notices provide for all disputes being settled by arbitration and for the constitution of courts for that purpose before the 1st of May, when the masters require the proposed new regulations to come into force. This section of the trade has not yet adopted the system of arbitration which has worked so admirably under Mr. Kettle in the other branches.

STAINED GLASS.

A STAINED glass window has been erected in the Episcopal Church at Stirling to the memory of the late Colonel Priestly, of the 42nd Royal Highland regiment. The window is from the establishment of Messrs. Ballantine, of Edinburgh.

St. Mary's Church, Cowes, has just received a great addition to it in the shape of a handsome stained glass window, which has been presented by Lady Fellowes and Mrs. Parker as a memorial window. The subjects illustrated are "Moses striking the rock," "The Baptism of our Lord," and the "Passage of the Red Sea." In the tracery piece over the other windows is a large quatrefoil, in which is depicted "Our Lord in Majesty." The treatment of the whole of the subjects and ornaments are in the early Gothic type, harmonising with the building.

LEGAL INTELLIGENCE.

A BREACH OF THE BUILDING ACT.—At Clerkenwell, on Wednesday, Mr. William Thomas Purkiss, of 29, Bellevue-villas, Seven Sisters'-road, was summoned by Mr. John Turner, the district surveyor of the eastern division of Islington, for having erected a building at the rear of No. 40, Grafton road, after the same house had been built, with walls only 4½in. thick, the door frame flush with the face of the brickwork and the roof covered with boarding, contrary to the rules of the Metropolitan Building Act. Mr. Purkiss not being in attendance at the time mentioned in the summons, the magistrate, after deferring the hearing until the other summonses had been disposed of, then considered the case, when Mr. Turner stated the building was erected at the end of the beam building of the house, between it and the dust-bin; that it was about 8ft. in length and 4ft. wide, and about 4ft. 6in. high, and that there were eleven other buildings exactly of the same construction added at the rear of the other houses erected by Mr. Purkiss in the Grafton-road. The service of the notice to amend having been proved, the magistrate said the question

with him was, whether this was a building within the meaning of the Act, when, upon his referring to the statute, he decided it to be so, and ordered that the said building be amended as required by the district surveyor, or removed within the period of one month, and that 12s. 6d. costs be paid. A second summons for a similar building at the rear of No. 2, Gloucester-road, was then gone into, when Mr. Turner explained the building in this case was larger than the former, and there were eight others similar in construction at the rear of the houses erected by Mr. Purkis in the Gloucester-road. The magistrate made a similar order and award of costs as in the preceding case.

DISPUTE BETWEEN A BUILDER AND THE BOARD OF WORKS.—A case of some interest was heard before Mr. Ingham at Wandsworth, on Wednesday, upon an adjourned summons against Mr. Joseph Liddiatt for building houses in the Bridge-road, Battersea, beyond the line of frontage as determined by the superintendent architect of the Metropolitan Board of Works. It appeared that the defendant began building before the line of frontage was determined, and afterwards completed his houses. On proceedings being taken against him, he memorialised the Metropolitan Board to allow his houses to stand, but they declined to make any order, and the magistrate was now called upon to have them demolished. Two cases in point were cited. One was a case which had been heard in the Court of Common Pleas, and it was read in support of the defendant's objection. In that case the judges were of opinion that the decision of the superintendent architect was not final, and that the magistrate had power to review it. The second case was of later date, and was heard in the Court of Queen's Bench. It was read by Mr. Corselli's, the clerk of the local board, in support of the summons, and it was to the effect that the judges held that the decision of the superintendent architect was binding upon the magistrate.—Mr. Ingham said his own opinion was that he was bound by the decision of the superintendent architect, and that he was called upon to determine whether the buildings were beyond the line. He recommended the defendant to apply again to the Metropolitan Board. He did not think he ought to be punished in that serious way by the destruction of a large quantity of valuable property for having been obstinate.—The summons was then adjourned for a month to enable the defendant to make the application, the magistrate giving him permission to use his remarks.

THE CROSBY BRICKKILN BURNING CASE, LIVERPOOL.—On Monday Mr. Serjeant Wheeler gave his final decision in the case of De Costa *v.* Humphreys. The case, which was tried before his Honour and a jury on the 28th ult., was an action by Mr. De Costa, shipping agent, of Liverpool, against Mr. William Humphreys, brickmaker, at Crosby. The plaintiff, whose residence is near the defendant's brickkiln at Crosby, complained that the brickkiln was a nuisance to him, and had injured the fruit and trees in his garden, and the smoke and vapour from the brickkiln and chimney had also penetrated into the house, to the injury of his family's health. He claimed damages for the loss of fruit, damage to his trees, and the offensive smell and annoyance to the house, amounting to £50. The final decision was postponed until Monday, when his Honour directed a verdict to be entered for the defendant, with costs. The case excited considerable interest amongst the parties concerned, as well as the inhabitants at Crosby, as an opposite verdict involved the closing of the brickkiln and works altogether, the defendant stating that he could not do more than he had done by the introduction of machinery in order to condense the smoke and vapour so as to prevent its being an annoyance to the neighbourhood.

NOTICES OF BOOKS.

Report on the Proper Principle of Drainage to be Adopted in the towns of Oxford, Eton, Windsor, and Abingdon. C. B. EWART, Lieutenant Colonel, Commanding Royal Engineer, London District. Printed by order of the Secretary of State for the Home Department.

IN pursuance of instructions received from the Home Secretary in June last, Colonel Ewart visited the towns above named, and carefully investigated the arrangements already existing for the disposal of sewage, examining the country in the immediate vicinity to such an extent as he deemed requisite.

Dismissing as either pernicious or impracticable the cesspit, earth-closet, and purifying systems, he proceeds to consider the three systems of carriage of sewage by water, viz, the "joint system," the "mixed system," and the "separate system." Under the joint system, all the rain which falls within the drainage area is carried into the same sewers as the sewage matter, and passes with it, in a polluted state, to the outfall. Under the separate system the sewage is carried in separate sewers, and the rainfall passes into the rivers or is absorbed by the surface on which it falls. The mixed system is a modification of the first two systems, under which a portion only of the rainfall passes into the sewers, the rest being carried into natural channels. Colonel Ewart's objections to the joint system are, the insufficient size of the sewers, the accumulation of sand and other street material carried into them by the surface water at the bottom of the sewers, the injurious effluvium which proceeds from this mass of stagnant matter and forces its way into streets and dwelling-houses, and the danger to the public health from the overflows. He also considers that these objections equally militate against the mixed system. He therefore recommends to the Home Secretary the separate system as the proper method to be applied to the towns comprised in his report, and advises that a complete system of sewers should be at once laid out to receive all the sewage matter, that the rainfall should not be allowed to enter into these sewers, but either be stored for domestic use or allowed to run into its natural channels, that a complete system of water supply should be provided where it does not at present exist and that the water and sewage works of each town be, if possible, under the control of the same local authority. He further recommends that a sufficient area of land be selected and obtained for the purpose of irrigation, the quantity of land requisite being, he calculates, one acre to every 100 of the population, in order to admit of farming the lands subject to a judicious rotation of crops.

The A. B. C. Sewage Process. Second edition. Elliott Stock, 62, Paternoster-row.

THIS pamphlet contains accounts of the experiments recently made at Leicester, Tottenham, and Leamington on the purification and utilisation of sewage.

The A. B. C. mixture (so called from the initials of the three principal ingredients—Animal-charcoal, Blood, and Clay) is a compound which, when dissolved in either sewage or water, and added to the sewage, is said to produce an immediate precipitation of the greater part of the injurious matter in the form of large flakes, which rapidly fall to the bottom; the supernatant liquor being then allowed to flow into a tank, a small quantity of a solution of perchloride of iron is added to it, and this precipitates the sulphuretted hydrogen dissolved in the water, and removes the last traces of smell. To these four ingredients it has been found desirable to add a proportion of alum, which is said greatly to accelerate the process.

We have before alluded to the experiments which have been made, and, therefore, now only extract what are said to be the actual results:—

1.—The sewage contained 43.02 grains per imperial gallon of organic matter. Of this the A. B. C. process precipitated 33.33 grains, leaving only 9.69 grains in the water, and this from an average of fifty samples taken at intervals during the progress of the experiment.

2.—Hitherto the lime process has been acknowledged to be the best, and the Leicester mode of conducting it to be the best of its kind. The A. B. C. contrasts most favourably with this, inasmuch as, from samples taken at the same time from each, the water contains as follows:—

Water from the A. B. C. contained 9·69 grains per imp. gal.
" " lime " 16.18 " " "
having precipitated from the sewage the following proportions:—
Organic matter precipitated by the A. B. C., 77.48 per cent.
" " " lime 62.39 "

There are also other alleged advantages, for which we must refer our readers to the pamphlet. We think there is little doubt of the efficacy of the A. B. C. mixture, but we fear there is a danger of a speedy exhaustion of the supply of its chief component part.

A Rudimentary Treatise on the Manufacture of Bricks and Tiles, containing an outline of the principles of Brickmaking. By EDWARD DOBSON, A.I.C.E., M.I.B.A., author of the "Art of Building," "Masonry and Stone-Cutting," "Foundations and Concrete Work," &c., &c. Revised and corrected by CHARLES TOMLINSON, F.R.S. Fourth edition. With additions by ROBERT MALLET, A.M., F.R.S., M.I.C.E., &c. With illustrations. London: Virtue and Co., 26, Ivy lane. New York: Virtue and Jorston. 1868.

MR. DOBSON'S name is too well known in connection with other volumes of the "rudimentary series" to require that we should do more than state that the present edition of "bricks and tiles" has been carefully revised, and contains valuable additions to the contents of its three predecessors. The author has done everything in his power to render the information he lays before his readers complete and reliable. He mentions in the preface that, with a view of collecting accurate and precise details of the manner in which the process of brick and tile making was carried on in different localities, he drew up a series of questions and distributed them among those most likely to assist him in his researches. Some of these naturally went astray, but the majority were returned, containing valuable particulars and a large amount of practical information. After investigating what may be termed the general "art of brickmaking," examples are given of the method of conducting the operation in Holland, in Nottingham, Staffordshire, Great Grimsby, Suffolk, and London. Every district has, as may be expected, some little point of practice or usage, as it might be termed, differing from those of its neighbours, but the main features are very similar in all. A description is also given of the application of machinery to the same purposes and the recent improvements introduced since the year 1863, including Whitehead's improved clay-crushing and grinding roller mill, and other machines by the same maker. The manufacture of tiles is also treated of, particularly those of an encaustic character. This description of tiles has lately come very much into use, especially for pavements, borderings, and a variety of other useful and ornamental purposes. In fact, a work treating of brick manufacture could scarcely be regarded as complete were this branch of the subject altogether omitted. The same remark holds good respecting drain pipes, an enormous quantity being now employed in drainage and other sanitary works. For pipes of limited size up to about 18in. in diameter, they constitute the best means that could possibly be used for accomplishing the required object. The amateur or professional man who may desire to thoroughly "make up" the whole art and science of brick and tile making, will find that in Mr. Dobson's work it is treated in a manner which will enable him to master all the branches with the least amount of labour and trouble to himself.

A Practical Treatise on Heat as applied to the Useful Arts, for the Use of Engineers, Architects, &c. By THOMAS BOX, Author of "Practical Hydraulics." London: E. and F. N. Spon, 48, Charing Cross. 1868.

UNDER the above title we have a valuable little volume which combines the scientific and the popular style in a very happy mean. It is capable of being studied as a text book and also read as an interesting treatise. The aim of the author has clearly been to enlist the attention of his readers, and to facilitate the acquisition of knowledge by divesting the necessary medium of many of its unattractive features, not to use any stronger term. All the usual standards have been adhered to, such as the "unit of heat," "specific heat," "unit of temperature," and others, so that anyone who has investigated the subject of calorie in different works will find himself quite at home in the present. Most of the practical applications of heat to industrial, manufacturing, and useful purposes are investigated, and explanations given of what may, at first sight, appear to be unaccountable. The theory of combustion is exemplified by allusion to steam boilers, the relative effect they produce in proportion to their size, whether they are long or short boilers, and the necessity there exists for the proper regulation of the fire and the blast. Chapter V., on chimneys, will be found exceedingly well illustrated by examples, and the author draws a comparison between them and the discharge of pipes, which, to all intents and purposes, they really are, only we are accustomed to regard a pipe more as a medium for the conveyance of water than of air. The much-vexed question of heating air is entered into, and the various methods of accomplishing the operation described. They may be briefly summed up as consisting of the use of open fireplaces, stoves, steam pipes, and hot water pipes. The last method, upon the whole, would appear to be the preferable one, and is that which has been employed in the majority of instances with respect to churches and other public and private buildings.

Passing on to chapter XII. we come to the transmission of heat and laws of cooling. Heat may, generally speaking, be transmitted in three different ways—by radiation, conduction, and reflection. From a table, constructed from the formula of Mr. Cauchy, by which the temperature attained at a given depth by any substance in a given time may be calculated, sand is the most difficult substance to heat, and air the easiest. There is also an excellent table giving the loss of heat by horizontal pipes, of different diameters, cased in woollen felt or cotton wool, and covered by thin canvas or a jacketing of some non-conducting material. The loss occasioned by radiation is calculated from the well-known formula of Dulong and Petit. It would, in fact, be impossible to write a treatise on the laws and applications of heat without borrowing from the French *savans*, as they have been more assiduous than ourselves in furthering the cause of all the sciences, both pure and applied. Dulong and Petit, Péclet, Pouillet, Ganot, and many others, have been foremost in conducting experiments

and deducing formulas and laws, not only with respect to the subject of caloric, but of every other branch of physical science. The question of ventilation, one of the most important that can possibly arise, considering its influence upon the sanitary welfare of the inmates of large cities and towns, is treated as it undoubtedly deserves, and particular notice made of the best means to effect the adequate ventilation of schools, churches, and hospitals. The volume concludes with a chapter upon winds, and their action upon general ventilation, and as purifiers of the atmosphere. There are abundance of practical examples adduced as illustrations of the rules laid down, and anyone, by due attention and study, can thoroughly master them all. The volume is printed in capital type, and its whole style and get-up are such as to recommend it to the amateur, the student, and the professional man.

Our Office Table.

Some additions have been made to the Egyptian Saloon in the British Museum in the shape of some interesting statues, and a picture said to represent Thermuthis, the daughter of Pharaoh, who saved the infant Moses.

On Monday, the 9th inst., Benjamin Armitage, Esq., presented the International College, Spring-grove, with marble busts of H. R. H. the Prince of Wales and of Mr. Cobden, sculptured by Mr. M. Noble. A further portion of the college buildings is now being erected by Messrs. Holland and Hannen, at the cost of about £10,000, under the superintendence of the architects, Messrs. Norton and Massey.

The death of Edward Hildebrant, the celebrated painter, which we announced three weeks back, is followed by the appearance of six beautiful chromo-lithographs after water-colour paintings by him. R. Wagner, of Berlin, is the publisher, and the agents for England and France are Messrs. Goupiel and Co., of Southampton-street. Additional interest attaches to these souvenirs of the deceased artist from the fact that the proprietor of the originals, from a chivalrous desire for the spread of the fame of Hildebrant, of whom he was an intimate friend, has freely permitted them to be reproduced. They, moreover, widely differ from the general run of chromo-lithographs. The usual hard and harsh outlines are altogether removed, and the softness of the colours is beyond anything yet attained.

Notice has been given that application is intended to be made to Parliament, in the ensuing session, by the Mayor, Aldermen, and Commons of the City, for leave to bring in a Bill to empower the Commissioners of Sewers for the City of London and the liberties thereof, to require gas, water, telegraph, and other companies and corporations, societies and persons, to make use for the purpose of laying down, after the passing of the intended Act, gas, water, and other pipes, tubes for telegraph wires, and any other pipes or apparatus in any subway already formed, or in course of construction, or to be formed in or under any of the streets. To restrict the breaking-up of the surface of any such street. To require the alteration and the removal into the subways of pipes, tubes, wires, and other apparatus laid before the passing of the intended Act, and to prohibit the continuance and maintenance, except in the subways, of pipes, tubes, wires, and other apparatus laid before the passing of the intended Act. To empower the Commissioners to execute works, and to remove pipes, and to place pipes in the subways, and to break up the soil and pavement for that purpose. To provide for the maintenance of the pipes and apparatus in the subways by the parties to whom they belong, and for the supervision thereof by the Commissioners and their officers; and to vary and extinguish all rights and privileges of any company, society, corporation, or person which would interfere with the objects of the intended Act.

Pilgrims to Jerusalem will in future find the Holy Sepulchre restored, and the interior bronze decorations completed ere long. The painting of the cupola is finished, and the railings of the "gallery of lamps" are about to be sent from Paris. France—in fact, the Empress—has taken a leading part in this work.

The Smithfield Club Cattle Show is to commence at the Agricultural Hall, Islington, on Monday, December 7, and will continue open during the four following days. The aggregate amount of the prizes is £2,300.

The Home Secretary, it is stated, proposes to transfer from the police to the Metropolitan Board of Works the supervision of dangerous structures in London. The Board have, in answer to inquiries, signified their willingness to undertake the duty.

The Spanish Minister of the Colonies has directed that materials imported from abroad for roads, railways, and other public works in Cuba, Porto Rico, and the Philippines shall be exempt from duties.

Mr. Taylor, the pastor of a Baptist congregation in Kenosha Wisconsin (U.S.), is justly entitled to the appellation of a working minister. The tall spire of the edifice was greatly in need of a coat of paint; a painter by trade could not readily be found to undertake the difficult job, therefore Mr. Taylor proceeded to do the work himself. The church spire is tall and slender, the ball on the top of the rod being 100ft. from the surface of the ground. He succeeded, with a little help, in raising a slender ladder from the bell deck, reaching nearly to the brackets below the top ball of the spire. On this he ascended, and, standing on the small iron brackets, gave the ball two coats of paint. The most difficult part of the work, however, was to paint the long space of the spire below him. By the help of a line he drew up a rope, fastened it round the rod and then around his body, and swung off fearlessly from his standing place. By readjusting and lowering himself in the ropes as occasion required, he was enabled to swing himself around on all sides of the spire, giving a good coat of paint all the way down to the deck. This is, perhaps, not the first time a daring feat of this kind has been performed, but very likely there are few men unpractised in performances on the rope who would venture to dangle in the air at such a fearful height.

The Poplar District Board of Works have taken action under Mr. Torrens' Act. Two houses in Barr's-alley, Robin Hood Lane, were reported by the medical officer as unfit for human occupation. They were visited by the surveyor, who describes them as having two rooms each: they are approached by a covered passage 20ft. in length and 2ft. 9in. in width; the ground floor of both is below the surface of the ground; the ceilings are about 6ft. high; the bricks and plastering are decayed from damp, and the smell is offensive. The privy is in bad order, and the drainage defective. Houses and privy are devoid of water. There were a man, his wife, and four children in each house. The board passed a resolution ordering the landlord to demolish the houses within a period of three months.—*Lancet*.

At the annual general meeting of the Royal Scottish Academy of Painting, Sculpture, and Architecture, held in the library of the Academy, at Edinburgh, on Wednesday week, Mr. J. Dick Peddie, architect, was elected associate of the Academy.

Velocipede building now forms an important branch of trade in Paris. There are not only manufactories of these new locomotives, but there are foundries where the iron work of which they are composed is cast. One of these employs 250 workmen, and finishes off twelve velocipedes per day for a coachbuilder of Lyons, who sells them at the rate of twenty per day. An expert driver can do ten miles and a quarter (that is, sixteen kilometres) in an hour, but the average rate of travelling is ten kilometres in the sixty minutes (that is, six miles and a half), and with the same fatigue which would be experienced by walking at an ordinary pace during that time. The effort a man makes to advance 3ft. will carry him 9½ft. forward on a velocipede, but naturally on condition that his machine is well built and works easily. The ordinary price of a good one is £12.

The Metropolitan Board of Works has authorised the establishment of telegraphic communication between the firemen's station at Westminster and the new fire brigade station in course of erection in Adelaide-road, St. John's Wood, at an annual cost of £40, and between the latter station and that at Hampstead, at an annual cost of £20.

The Board of Works has just completed the re-paving of the Parliament Square, Edinburgh, and on Wednesday a stone, marked "I. K., 1572," within an oval, was set to mark the burial-place of John Knox.

The twenty-first annual dinner in aid of the Builders' Benevolent Institution will take place on Thursday next, at the Freemasons' Tavern; George F. Trollope, Esq., the President of the institution, in the chair.

The *Echo de Saone-et-Loire* gives the following interesting details:—Commandant de Reffye, orderly officer of the Emperor, and M. Bertrand, Conservator of the Museum of St. Germain, delegated by his Majesty, lately arrived to ascertain the results of the latest excavations at Beuvray. A Gallic mural rampart, with all its details of construction, answering to the description given by Cæsar, has been traced out over a length of 500 metres, and the entire system of the fortifications of the place has been laid bare. The foundations of the works are everywhere preserved, and the visitors themselves were able to take for the museum the iron clamps remaining in the woodwork. They saw, still in their original position, in the centre of the right redoubt, thirteen cinerary urns placed in a line, and containing ashes. A not less curious discovery is that of a sort of arsenal, which has furnished information, hitherto unknown, respecting the military condition of the Gauls. Smelting furnaces and forges of a rude construction were attached to the buildings which commanded the entrances. Four hundred Gallic medals, and a single Imperial one, bearing an early date of the reign of Augustus, already form an historical series of some considerable interest.

The *Lancet* regrets to hear that the staircases of the new St. Thomas's Hospital are to be constructed of Portland stone, a substance too soft to withstand the wear and tear of traffic, and believes the combination of wood and metal (Hawksley's patent), similar to that in use at the metropolitan stations, would be found to answer better.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Geographical Society, 8.30.
Society of Arts.—Opening meeting, 8.

TUESDAY.—Institution of Civil Engineers.—Discussion on, 1st, Mr Henderson's paper on "Lighthouse Apparatus and Lanterns;" 2nd, "Roman Rock Lighthouse, Simon's Bay, Cape of Good Hope," by Mr. J. F. Bourne, M. Inst. C.E.

WEDNESDAY.—Society of Arts.—"A Glance at the Past and Present of the Society of Arts, with some Suggestions as to the Future," by S. F. Davenport, Financial Officer of the Society.
Geological Society, 8.

FRIDAY.—Architectural Association.—Annual reports and discussion thereon.

SATURDAY.—Associated Arts Institute.—Exhibition of sketches, subject, "The Tempest," [illegible]; and a meeting—Discussion, Question, "Does the Literature of a Nation to any extent influence its Art?"

Patents for Inventions

CONNECTED WITH THE BUILDING TRADE.

603. R. HEATHFIELD. IMPROVEMENTS IN THE MANUFACTURE OF CUT NAILS. Dated February 22, 1868.

The patentee claims manufacturing cut nails from hoops or strips of iron [illegible] steel, the edge or edges of which are rounded or bevelled or are of a V or diamond shape in cross sections, substantially as described and illustrated, whereby the nails cut from the said hoops or strips are more readily driven than [illegible] nails.—Patent completed.

610. T. LYTHGOE AND H. THORNTON. IMPROVEMENT IN THE CONSTRUCTION OF WALLS, FLOORS, AND ROOFS FOR DWELLING HOUSES AND OTHER STRUCTURES, AND [illegible] APPARATUS [illegible] THEREIN. Dated February 26, 1868.

The invention consists, first, in lining the wood or other frame or mould into which the concrete is filled with an improved compound having a hard and smooth surface. Second, in forming the outer and inner surfaces of the wall of fine concrete, which is run in between the outer frame or mould and a small inner frame. Third, in certain improved apparatus employed in the construction of walls and other parts of buildings made of concrete. Fourth, in attaching to the inside of the frame or mould triangular or other shaped projections placed horizontally and vertically, or otherwise, which projections produce corresponding recesses in the face of the building in imitation of the joints of the stones or panels or other designs, and in making recesses in the mould to produce ornaments

or other designs in relief. Last, in certain improved modes of constructing floors and roofs with bars of T-iron and concrete.—Patent completed.

674 H. CHAMBERLAIN, J. CRAVEN, AND H. WEDEKIND. IMPROVEMENTS IN BURNING BRICKS, LIME, CEMENT, &c. (Partly a communication.) Dated February 24, 1868.

This invention relates to two previous patents dated respectively December 22, 1859 (No. 2918), and June 24, 1864 (No. 1566). According to the present invention, it is proposed to combine with kilns constructed on the principle set forth in the specification of the patents before referred to, a system of forced combination obtained by the employment of a fan blower or exhauster situate on the outer or inner circumference, or on the top of the burning chamber of the kiln, and dispensing with the use of the usual chimney and smoke chamber.—Patent abandoned.

687 T. S. WHILOCK AND H. HARFORD. IMPROVEMENTS IN FASTENINGS FOR WINDOW SASHES. Dated February 28, 1868.

In constructing fastenings for window sashes, the inventors place across the channel in the frame of the window in which the lower sash works a metal bedplate in a dovetail recess, in which a dovetail plate slides horizontally. The dovetail plate is fixed to a vertical bar, which also slides horizontally, the bar having on its inner face two projecting pins or studs. The bar works in an opening made in the bead ing on the outer edge of the channel in which the lower sash works. The sliding bar is pressed inwards by a spring, so that when the bar is in its normal position, it fills up the opening in and forms a continuation o the beading. By means of a small bolt on the side of the window frame the sliding bar described may be fixed or rel ased. On the inner side of the lower sash a series of holes is made, with any two of which the pins or studs on the sliding bar may engage and thereby fix the sash in its closed position, or fix it at any required height in the frame. In order to unfasten the sash, the small bolt is first withdrawn, so as to liberate the sliding bar, when the latter may be pressed outwards, so as to withdraw its pins or studs from the holes in the sash. The sash may now be raised or lowered to the required extent, after which the sliding bar is loosed from the hand, when it is pressed back or inwards by its spring. The studs or pins on the sliding bar are thereby made to engage with the holes in the sash, and fix it in its closed or adjusted position. By shooting the small bolt the sliding bar is fixed.—Patent abandoned.

678 J. LEACOCK. IMPROVEMENTS IN PAVING FOR STREETS, ROADS, AND WAYS. Dated February 28, 1868.

This invention has for its object the construction of paving by using blocks or pieces of granite, syenite, or other suitable material, provided with holes in the same, and disposed in series or sets combined in one block, the holes forming the sets or rows to be sufficiently close to each other to be capable of being easily opened by a tool, so that blocks prepared in accordance with this invention shall afford a safe foothold for horses and other such like animals, and yet present such an even surface as required for wheels to travel on; and in case of severe traffic the level will be retained in proportion to the surface of the blocks, as against the single set, or about (say) twelve times to one.—Patent completed.

705 W. ROLLO. IMPROVEMENTS IN THE ARRANGEMENT AND CONSTRUCTION OF WATER-CLOSETS. Dated March 2, 1868.

This invention consists in using an air vessel of special construction to which the branch pipe from the water supply main pipe is directly connected, and the necessity for using a tank or cistern situated at a higher level than the pan of the closet is avoided.—Patent abandoned.

714 W. E. GEDGE. A MINERAL PAPER-HANGING INTENDED TO PRESERVE APARTMENTS FROM DAMPNESS. (A communication.) Dated March 3, 1868.

This invention consists in the preparation and application of a paper hanging termed by the inventor "mineral paper," the object of which is to preserve apartments against damp without suppressing it, and by means of coats of paint applied on a paper of any kind and of any size. This painting must be composed only of materials obtained from lead, such as minium or red lead, ceruse or white lead, litharge, calcined ore or lead ashes, which may be applied with any of the liquids used in painting. This paper bears a relief, forming ridges, this relief being composed of sand or of any material which is not decomposed by damp. These reliefs in ridges permit the damp to circulate without being constrained to rise again or to descend.—Patent completed.

718 J. BARKER. CERTAIN IMPROVEMENTS IN THE METHOD OF CONSUMING SMOKE, AND IN THE APPARATUS CONNECTED THEREWITH. Dated March 3, 1868.

The patentee claims, first, the novel employment, adaptation, and use of regularly feeding the furnaces of steam boilers with fuel by means of revolving shovels in connection with the mechanism described, or any slight modification thereof. Second, the novel employment and use of gas burners situated in the flues of boilers for the purpose of consuming smoke, together with the general arrangement of mechanism constituting these improvements, as described.—Patent completed.

722 J. MANLY. IMPROVEMENTS IN THOSE KINDS OF NAILS WHICH ARE USED UPON FURNITURE. Dated March 3, 1868.

The patentee claims the combination of a cast head with a wire, point, or shank in the manufacture of certain kinds of nails, affixed or put together by pressure, substantially as set forth and described.—Patent completed.

723 W. SPENCE. IMPROVEMENTS IN MACHINES FOR MAKING NAILS. (A communication.) Dated March 3, 1868.

This invention relates to the manufacture of nails from metal in a cold state, and consists in taking a bar drawn to the requisite section for the nails to be made therefrom, then removing from the same a series of small portions corresponding with nails of different dimensions, afterwards taking from another face of the bar another series of small portions, answering the purposes of brads; and last, in forming a series of larger nails.—Patent completed.

720 H. KENNEDY. AN IMPROVED MACHINE FOR CUTTING FILES. Dated March 3, 1868.

This invention relates to a machine wherein the file blank is supported below a vibrating cutter, which, by a succession of blows, forms the teeth from end to end of the said blank, either the cutter or the blank being caused to travel in the direction to cause the teeth to be cut regularly from end to end of the same. The nature of the said invention consists, chiefly, in regulating, controlling, and varying the movements of either the cutter or the file blank so that the teeth cut in the latter are not exactly parallel with each other; also in the peculiar construction and arrangement of the mechanism for supporting and adjusting the file blanks, in the novel formation of the cutter, and in the mode of and means for operating and adjusting the same.—Patent completed.

740 E. CLIFTON. IMPROVEMENTS IN ADJUSTABLE DOOR HANDLES. Dated March 4, 1868.

This invention relates to door handles or knobs and spindles which are capable of adjustment to the thickness of the door. The patentee employs the ordinary square spindle, one end of which may be permanently fixed into one knob, and the other end having screw threads formed on the angles to screw into the other knob, which is by preference (but may or may not be) bushed with metal. In order to secure the knob when screwed on the spindle to the thickness of the door, he applies a cotter in which is a slot hole, one part fitting the square of the spindle and the other part being round or sufficiently wide to allow of the spindle turning therein. This cotter is either fitted into a dovetail slot formed across the face, or that part of the knob towards the door, or it may be passed through a slot formed in the shank of the knob. The said cutter may be held in position by the rose or washer, which may be either screwed on the knob or on the door, or the said cotter may be made to spring, and thereby remain or keep in position, so as to hold the handle as adjusted to the door.—Patent completed.

743 A. M. CLARKE. IMPROVEMENTS IN PAVING ROADS, STREETS, OR WAYS. (A communication.) Dated March 4, 1868.

This invention relates to an improved system of metallic paving for roads, streets, and ways. The paving is formed of blocks of cast iron of about 8in. square, having four or other number of perforations at their centre for allowing the rain water to run through. The surfaces of these blocks are further grooved at right angles, the said grooves communicating with deeper cross channels, which are inclined so as to conduct the water to the holes above mentioned. The surface may further be steeled if desired. The interior of these blocks is so arranged that the ribs at the angles form ducts for the rain water.—Patent completed.

TENDERS.

ACTON.—For the erection of a public house, stabling, &c., Acton lane, Acton, W., for Wm. Williams, Esq. Mr. Edwd. Monson, jun., architect. Quantities supplied by Mr. D. W. Young:—

Harding	£1565
Messrs. Chamberlain	1339
Adamson and Son	1328
Wright (accepted)	1209
Welch	1195

CHEDDAR VALLEY.—For erecting the Axbridge Railway station:—

Brock, Bristol	£2700 0 0
Searl, Bridgwater (accepted)	1843 13 9

COWES, ISLE OF WIGHT.—For erecting new baths at Cowes, Isle of Wight. Quantities supplied:—

Chinnock	£4365
Nightingale	4567
Wheeler	4180
Stephens	4100
Thomas	3903

ILMINSTER (Somerset).—For the erection of a minister's house, schoolrooms, &c, in connection with the Congregational chapel, Stoke-sub-Hamdon. Mr. R. C. Bennett, architect:—

Tucker	£2077
Wilton	1986
Pudding and Rendall	1980
Chapman	1600
Staple and Bartlett (accepted)	1488

LONDON.—For erecting model dwellings, Grosvenor-mews, Bond street, for the St. George's parochial association. R. H. Burdon, architect. Quantities supplied:—

Morris	£2945
Patman and Fotheringham	2875
Fish	2630
Gammon and Son	2685
Longmire and Barge	2643
Stoner (accepted)	2615
Keys and Head (too late)	—

NORTH WOOLWICH.—For building five cottages and finishing five carcasses, near North Woolwich Gardens. Messrs. W. and T. Stone, architects:—

Batterley	£1625
Davis	1500
Clark	1266
Perry	1120

STANTON DREW.—For erecting a parsonage:—

	House.	Stables.	Roads.	Total.
Beavan	£1814 0	£289	£85	£2188 0
King	1759 0	260	29	1979 0
Davis	1570 0	290	—	1860 0
D. C. Jones	1555 0	242	25	1832 0
W. Jones	1520 0	225	40	1785 0
Brock	1423 10	203	20	1646 10
Hayes and Sons	1143 0	150	20	1613 0
Diment	1283 0	225	21	1535 0

COMPETITIONS.

INDIA.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

PRIORY ESTATE, DOVER.—December 15.—For laying out about 13 acres of building land. Premiums of 50 and 20 guineas. Mr S. Finnis, Biggin-street, Dover.

NORTHAMPTON.—November 23.—Designs for the erection of a new central hall at Free Grammar School. T. B. Housman, secretary, St. Giles square, Northampton.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

LEICESTER WATERWORKS.—December 8.—For the construction of a large storage reservoir, &c., and for the erection of an engine and boiler house, and other works. J. H. Williams, secretary, Waterworks offices, Bowling Green-street, Leicester.

PENZANCE.—November 28.—For the improvement of the harbour of Mousehole, in the parish of Paul, near Penzance, in Cornwall. Rodd and Cornish, solicitors to the Commissioners, Penzance.

ROCHDALE.—November 24.—For lighting the new town-hall with gas. Z. Mellor, town clerk.

ROCHDALE.—November 24.—For warming and ventilating the new townhall. Z. Mellor, town clerk.

TOWER SUBWAY COMPANY.—November 30.—For the construction of lifts. Mr. P. Barlow, engineer, 26, Great George-street, S.W.

MARYPORT.—November 30.—For laying street gas mains, and for excavating, restoring, and sustaining the streets. J. Barwise, Harbour Office, Maryport.

November 30.—For the erection of a block of model buildings, near Tottenham Court-road. Mr. S. Legg, architect, 32, Bedford row, W.C.

HAMPTON COURT AND WALTON BRIDGES.—December 16. Tender for tolls. Mitra, Hamoton Court.

CHELSEA.—November 24.—For the construction of about 640ft. run of brick sewer. C. Lahee, Vestry hall, Kings road, Chelsea.

ADMIRALTY.—November 24.—For the supply of iron chain cables, &c. A. Brady, Registrar of contracts.

ST. JAMES'S CHURCH, GREAT YARMOUTH.—December 12. —For the erection of a portion of this church. J. P. Seddon, architect, 12, Park street, Westminster.

REIGATE.—For completing a residence at Reigate. J. F. Matthews, London road, Reigate.

ST. MARY ABBOTT, KENSINGTON.—For the construction of about 1,100ft. of brick sewer. Mr. J. Whitchurch, surveyor, 7, Lincoln's Inn Fields.

STREATHAM.—December 1.—For the construction of about 3,480ft. of brick sewers. A. A. Corsellis, Battersea rise, Wandsworth, S.W.

STOKE-ON-TRENT.—November 24.—For certain alterations and additions required at the Spittals Workhouse, in adapting and converting the old school buildings into sick and other wards, together with the other works connected therewith. C. Daniel, clerk to the guardians, Parish office, Stoke-on-Trent.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

W. King, York road, Wandsworth, stonemason—C. Cornes, King street, Hammersmith, carpenter—Joseph Moores, Poole, plumber—Charles Thomas, Alexandra road, Kilburn, plasterer.

TO SURRENDER IN THE COUNTRY.

R. Martin, Liverpool, contractor—J. Chesworth, Liverpool, estate agent—H. Halton, Hyde, Cheshire, joiner—D. Long, Hunstanton, Norfolk, carpenter—J. Foster, Leeds, plasterer—C. J. Welsh, Springbourne, Hampshire, painter—William Brooks, Barnley, plumber and glazier—John Emson, Wolverhampton, gas engineer William Robinson Levens, Middleton, builder—Henry Sharman, Ellesmere, builder.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

December 2, R. Payne, Little Pulteney street, Golden square, bricklayer—December 2, A. Powley, Warren street, Tottenham court road, plumber and glazier—December 4, T. Llewellyn, York street, Walworth, builder—December 4, S. Callard, Ashdown street, Kentish Town, builder—December 4, G. H. Hall, Willesden, builder—December 8, S. Benn, Great Horton, plumber and glazier.

PARTNERSHIPS DISSOLVED.

J. Whitehead and W. Helliwell, Halifax, chimney repairers and lightning conductor makers—W. Kellett and R. Kellett, Wigan, Lancashire, land and mining surveyors—Jemingham and Coleman, Peckham Rye, builders—Edwards and Co, Stainland, Yorkshire, stonemasons—Smith and Ward, Fenton, builders.

DECLARATION OF DIVIDENDS.

W. Sheppard, Gloucester, builder and contractor, first div. of 7s. 3½d., any Wednesday.

SCOTCH SEQUESTRATION.

Richard Lees, Edinburgh, builder, November 24, at 1

BANKRUPTCIES ANNULLED.

W. Miller, Lewisham, Kent, builder—C. Simonds, Euston road, Middlesex, builder.

THE BUILDING NEWS.

LONDON, FRIDAY, NOVEMBER 27, 1868.

MODERN ARCHITECTURE.—THE PHILOSOPHY OF FAILURE AND THE SECRET OF SUCCESS.

IT will be admitted by intelligent observers of all parties, cliques, and schools that modern architecture regarded from an art point of view is not a success. We have huge edifices, triumphs of engineering skill imposing piles of building resplendent with trophies of the stone-carver's craft, and magnificent erections of iron and glass, marvellous as specimens of metalwork, and gorgeous in their effect. Nevertheless we have no distinctive and satisfactory style, no precise principle of construction, no characteristic method of ornamentation, and no practical power of realising that idea of *beauty* which hovers in thought before the mind of every intelligent designer, which all true architects strive to grasp and make their own, and without which there can be no permanent pleasure in art work, no enduring satisfaction, or effectual fame. It is, therefore, of the last importance to search out the source of this failure. Until we discover the fault it is vain to hope for improvement.

It may seem but the repetition of a hackneyed truism to assert that the *true* and the *beautiful* are inseparable. Yet if we are not greatly deceived it is because in modern architecture these two qualities are regarded and treated as separable that the practice of art is a failure. As a matter of fact the attainment of beauty is proposed as an object altogether apart from the consideration of truth. For example, an architect sits down to design a building required for a specific purpose, and to be erected under certain prescribed conditions of cost, construction, ground plan as determined by the site, and accessory surroundings. What is his intention? What the task which he proposes to himself? First, he either resolves to adhere closely to his instructions and designs his building on a purely utilitarian principle, trusting to his ingenuity to make it beautiful by a subsequent process of ornamentation; or he struggles with the difficulties presented by his instructions, and contrives to eke out a tower here or a façade there, in order to give what he is pleased to describe as an artistic effect to his work, or, in other words, to make it appear beautiful. The supplementary application of ornament, of course, serves, as in the former case, to cap the process of beautifying. Now, we contend that in both of these methods of work truth is sacrificed; the realisation of the idea of beauty is proposed as an independent object, and hence the inevitable failure. The man who builds with a simply utilitarian object, regardless of beauty, and then adorns his building to make it captivate the eye with an appearance of beauty is practising an æsthetic fraud. His edifice is not beautiful in itself, he is conscious of its defect; hence he labours to give it a meretricious aspect by means of ornament. Is it wonderful if he fails? Is it strange if the art instinct of the public sees through the deception and rejects the sham? Again, the designer who distorts the constructional parts of his work with the aim to realise something of beauty is no less untruthful, inasmuch as the façade or the tower he contrives to produce are not necessary—they form no integral part of the utile edifice. The public eye quickly detects the artifice, discovers its hollowness, and, in contempt of the designer's disregard of truth, despises his work. In illustration of these supposed classes of work, and in proof that they are not imaginative, it is only necessary to instance the numberless hotels, stations, warehouses, and public buildings scattered throughout the country which in themselves are ugly, but to the perverted vision of a vitiated taste are made tolerable by an incrustation of cornices, carved friezes, statuettes, intricate metalwork and elaborate ornament. These are examples of buildings erected without a thought of beauty and beautified afterwards. The class of works which are untruthful in their form, and ape beauty rather than possess it, may be illustrated by the twelve or fourteen-roomed houses fashioned like castles, the insurance offices and banks built to resemble edifices of great civic importance. The cloistered bath and wash houses, the club houses and reading rooms, like Greek or Roman temples, the divans like ducal palaces, and the parish churches in town and country constructed as cathedrals—all these things are *deceptive*, and it is because they transgress the principle of truth and regard the attainment of beauty as an object to be gained apart from truth, and even in violation of its immutable and universal laws, that they are failures.

But a practical view of the question requires that we should make some attempt to answer the question, What is *truth* in relation to architecture? The affirmation of mere general propositions, however convincing, can serve no useful purpose. Confessedly, it is a task of great difficulty to define the precise conditions of architectural truth. On the first blush of the matter it is self-evident that there must be purity of intention in the design. If a man sets out with the purpose of building a barn, it must not be a Swiss villa or a Chinese joss-house that he plans—it must be a barn pure and simple. The practical error takes its rise in the false notion that certain objects are more respectable and pleasing than others, and, falling into the vicious practice of flattery, the architect deems it more complimentary to the feelings of his client or considerate to public taste to make his barn look like something very charming, in the shape of a light and graceful out-building, precisely on the same principle that he continues to render a twelve or fourteen-roomed house something like a castle. Now, truth would forbid all such misrepresentation of fact. Then, again, truth would interdict all meretricious ornament—that is to say, it would deter the use of embellishments properly so-called. It would require a grandeur, and a style and degree of ornamentation befitting the nature of the building and the purpose to which it was to be applied, but it would not allow the enrichment of a plain mass with a view to raise it to the pitch of beauty supposed to be possessed by a building of more elaborate figure. The ornament prescribed by truth would be suitable in kind and quantity to a mass of the form which it was proposed to decorate, and neither intended to conceal nor pervert its figure. If these two fundamental conditions of truth in architecture are fairly and honestly interpreted and applied—first, purity of intention in design, and, second, perfect consistency in the use of ornament—the inevitable consequence must be that the designer will be compelled, if he seeks *beauty* at all, to alter it in the original arrangement and configuration of the various parts of his building in its masses, and in close connection with absolute truth. This at once brings us face to face with the practical aspect of the subject. It is because architects design their works as objects of utility first, and then attempt to make them beautiful afterwards, that they fail. It is in the abandonment of this erroneous policy, and in the adoption of a method seeking beauty in the arrangement of masses, that we shall find the secret of success. A very little quiet thought and unprejudiced observation must suffice to convince any intelligent man that this view of the case is substantially correct. How numerous are the examples of good work marred by the vicious practice of subsequent enrichment. Take, for instance, three well known buildings; first, Salisbury Cathedral. No one who is well versed in architecture, or endowed with a faculty of eclectic taste properly cultivated, will, we presume, be found to estimate that building as a very noble or pure work of art. It is admitted by all to be weak, especially at the west front, and generally spoiled by the redundancy of its accessory masses and ornamentation. Nevertheless, let any one examine the masses of Salisbury Cathedral in the dull light of the evening or in the early morning, when the details are obscured; let him compare the spire with the base line and the general mass with its several parts, he will detect a harmony, a rhythm, and a consequent beauty which is altogether masked and rendered ineffectual by the mistaken character of the system of ornamentation. A still more striking illustration of our idea is to be found in the mass of the Victoria Tower of the Houses of Parliament. Seen in the dusk there is a grandeur and imposing effect produced by that structure which is altogether lost when viewed in a strong light, with its miserable details, so much below the mass in point of excellence, visible. St. Paul's Cathedral and the river elevation of Somerset House are equally notable examples of this marring of masses by injudicious efforts to enrich and ornament. Had the several architects of the works to which we have referred been content to treat their original conception without striving to make them appear more beautiful than their intrinsic form had rendered them the effect would have been *truthful* and infinitely finer. These considerations obviously point to conclusions that it is on the attainment of beauty in the management of his utilitarian design that the architect should concentrate his care and skill. This was the principle on which the designers of the best and purest epochs in the history of art acted. The works which have been preserved for us from the thirteenth century are eminently *truthful* in their intention. They tell the story of their use without disguise or prevarication. They do not seek to appear more noble or higher in the scale of beauty than they are placed as respects the arrangement, configuration, and balance of the masses of which they are composed. The ornament is never excessive, it never belongs to a class of building more elevated or elaborate than that to which it is applied; it never suggests the idea that the designer aimed to make his work look *enriched* or beautified. Simplicity and truth are characteristics of a style which all accept as thoroughly honest and pre-eminently respectable.

The error into which the Gothic revivalists have fallen is that they have attempted to reproduce the *form* of mediæval work but neglected the *spirit*. Now it must be evident that much of the architecture which we admire in its place, amid the associations of the thirteenth century, would be anachronic, however skilfully reproduced in the nineteenth century. What we want is a revival of the old spirit of manly out-spoken honesty and the love of truth which animated the old art-architects. Special developments of art are inseparably connected with conditions of time, place, and circumstance. We cannot live, and dress, or build as they did who lived in the thirteenth century, but we can subject ourselves to the same pure and simple influences of truth which swayed the minds whose creations we so thoroughly appreciate. We can pursue their method, we can eschew our modern mistake in divorcing the ideas of truth and beauty, and we can strive for that primeval phase of excellence which consists in the production of harmony and simple elegance. When we have mastered the principle of such a revival, and embodied it effectually and truthfully in the practice of art, then, and not until then, shall we have studied to some useful purpose the philosophy of failure and discovered the secret of success in modern architecture; then, and not

before, will be a reasonable prospect of developing a respectable style suitable to the necessities of the nineteenth century, and worthy of being handed down to posterity as an expression of our national taste and a register of our intellectual progress.

COLOURING SHOW DRAWINGS.

NEITHER the engineers nor the architects can consider themselves perfect in their respective professions unless they are first-rate draughtsmen; their knowledge in other branches and the ideas they may originate are alike useless unless they have perfect ability to transmit those ideas to the minds of others. No man either can consider himself a first-rate draughtsman unless he can both colour and shade well, unless, in a word, he has a certain amount of artistic knowledge and taste. The former may be acquired, but the latter can only be cultivated; it can never be created by education.

Drawings are usually placed in two classifications—line drawings and coloured drawings. Many professional men have a dislike to coloured drawings, and we fancy this dislike is more prevalent in Great Britain than on the continent. Certain it is that our continental neighbours pay more attention and devote more study and instruction to this matter than we do. Allowing for this dislike amongst us, it cannot be denied that a good line drawing, when properly coloured and shaded, has a pleasing effect, and is also the clearest possible exponent of a particular arrangement of parts. The colouring and shading give a distinctness to each separate portion of the whole.

The preparation of a first-class finished drawing is a matter involving at once labour, skill, and exceptional care, and, added to all these, experience; we must know beforehand to a great extent what effect each particular colour and every variation of tint will have on the general appearance of the whole. A drawing, to be the very best of its kind, must be commenced with that view; the finish can never be an afterthought. Care must be exercised at the outset in the purchase of the paper. Incontestably the best paper for such a purpose must be hand-made, and no paper enjoys wider or more deserved popularity in either of the professions than Whatman's. Some persons like it rough, others prefer it smooth; for our own part, we do not think any arbitrary rule can be laid down. The person about to execute the drawing must judge of what will suit his particular subject best. For very large work, a somewhat rough paper is very suitable, but for small pictures, the sort known as middling, or that which is the same quality as what is afterwards "hot-pressed," answers best. When the paper is to be strained, as indeed it should invariably be for finished work, "hot-pressed" answers very well, as the wetting takes a little of the size and very smooth face off the paper, leaving it sufficiently rough to take either flat tints or stippling with great facility. When the paper is being purchased, it should be, if possible, three years old; this is unfortunately, however, a matter of much difficulty, as there is but little old paper in the market, and the only means to obtain it is to try at some of the little out-of-the-way stationers, who may have old stock on hand. Old paper is best, because it is harder and more set than the new papers, it is not so "fluffy" and rotten, and bears stippling and washing much better. The sheet should be held on nearly a level with the eye, in a horizontal position, and opposite a strong light, to detect any flaws or imperfections in the paper, and which would often escape any but a careful scrutiny until strained, when the wetting would render it at once apparent when the sheet had become dry again; and sometimes the defect would not be visible till the picture might be more than half completed.

Having secured a good sheet of moderate thickness, the next step is to strain it. This is ever a troublesome and difficult matter to do successfully. It is not a thing that can be half done or indifferently done, because if not well done it is almost better left undone. The paper should be laid down on the board to which it is to be secured, with the face to be drawn on placed next to the board, which should of course be spotlessly clean and clear of the remotest trace of dust. The sheet should be then thoroughly wetted on the back with a large flat brush, such as is used for copying letters, and this being done, be turned over and the opposite side should be treated similarly. Some persons advise its being then wrapped in a clean cloth, and left so for at least half an hour. We confess we prefer to let it lie flat, and perhaps to lay a clean damp cloth over it, as being less likely to crack or injure the face, on the preservation of which depends much of the success of the colouring. The board should be at least an inch and a half larger than the paper both in breadth and length. The paper should be set as nearly square as possible, without resorting to a tee on the board. The edges should be all rubbed with hot strong glue for about a width of half an inch all round, on the side next the board, and the glue should be laid on with a small brush; and the draughtsman ought to begin at the centre of the length of the margin, and work to each end, doing the same on all the edges; and then, without any attempt to pull the paper, merely to let the margins rest down on the board, and, by means of a long straight edge, to press the glued parts down all round, so as to secure it firmly to the board. The whole should be left so for half an hour, care being taken to watch that no "cockling" of the glued edges took place by using the straight edge when necessary. After this the board may be leant against a wall for an hour or two, and then being laid on the bench a piece of old clean news or other smooth paper to be laid down so as to cover the whole of the paper. The following day the paper should be ready for use.

We have already stated that a good drawing must be commenced with the view that it should be so, and now the draughtsman must exercise all his skill to preserve his paper from soil or mark, and, above all, to avoid the use of rubber by every means in his power, as it spoils the paper for colour and renders it apt to pick up dust. In "inking in" his drawing, he must carefully avoid putting in any dotted lines till after the colouring has been completed, as the ink will wash up. Some persons wash the drawing over with a damp sponge after it has been "inked in," and this removes all superfluous ink, and leaves it ready for colour without any danger of the ink washing up. This proceeding is, however, defective, because the ink is liable to "smear" all over the paper, making the remedy worse than the disease.

In using the colours there are two distinct processes in finishing a drawing, viz., "tinting and shading," and it is optional which may be done first, but it is best as a rule to begin with the latter, as then the face of the paper is clear, and there is no chance of the shading colour and the body tinting mixing or washing up. In shading the draughtsman must consider attentively the character of the structure to be finished up, to study the relative position of the various parts, and to labour to make the picture at once as elegant and as distinct as possible. A great point in these drawings is that the shading should be forcible without being heavy. Shading is a very tedious operation to execute properly. Two modes may be adopted, each of which may be modified to suit the habits of the draughtsman. One of these modes is most applicable to large surfaces, and it consists in putting in successive works of the shading tint, carrying the first tint about half way over the surface, or nearly so, and then softening it off with a clean damp brush. This, and indeed the first three coats, should be very thin indeed, only enough to tint the paper, and then they may be gradually strengthened. Each successive coat should be narrower than the last, until it makes the shaded surface darkest in a line a little removed from the edge of the surface; and the shading should be perfectly smooth and flat, and melt away gently into the white light, which should be nearly midway between the centre and the line or edge next the light.

PAINTING ST. PAUL'S.

ART at all times has been naturally divided into the two great divisions of past and present, but never, it is certain, with that distinctness and wideness of difference that it is now in these days of rapid change. In old times the change was from one phase of a style of art to another phase following and growing out of it; in these modern times it is a change of *principles of artistic action*, as well as a change in styles of art. In old days this at least may be affirmed, that the works produced bear on the face of them evidence of the individuality that brought them into being, while the whole of the work professing to be fine art in these latter days is the result of a system of manufacture and the consequent *absence* of this so much prized and expressive individuality. Hence does it become more and more interesting and important every day to help and preserve all—and little enough it is—that remains to us of this individuality of artistic expression as exemplified in the works of the past, and it is this consideration which makes St. Paul's a building of very peculiar signification and interest, and what is now being done in it one of the most important practical art problems of this generation. If the subject wearies the reader it ought not to do so, and we feel that no small good will be done to the cause of art and artists if by any argument and possibility we shall succeed in bringing again to the light of day any—however small—section of the actual and real stone walling of the interior of St. Paul's Cathedral, and at the same time point out what might have been and perhaps yet may be done to *decorate* it. You cannot pull down St. Paul's and put up another building in its place, or put up a pole advertising the waste ground on which it stood "to let," like the site of a common city church, but it is possible to completely destroy the whole art value of this great cathedral by dint of ignorant experimenting, and by efforts to do something when you do not know what to do.

I should like to begin this somewhat difficult subject with an art axiom or common-sense truism, so as, if possible, to carry the reader fairly into the subject, and make him at least agree with the main proposition before us, which is, how to decorate St. Paul's artistically, and so as to vitally interest the general public mind in it, and increase, if possible, the beauty of the interior of this greatest of England's churches. I would begin by saying that it is the duty, the bounden duty of the public, and of the public authorities who represent them, and who do their technical and professional work for them, to employ the very best art means the age affords. If the Royal Academy, as most people admit, contains within it the best and highest of the artistic capacity which the time and country has produced, and St. Paul's be the noblest of our buildings, then I humbly submit it was the duty of the Dean and Chapter of St. Paul's, and of those whom they employed to advise them, to call in the aid of the *painters* of the Royal Academy in the decoration of St. Paul's Cathedral. No one, I think, will dispute this intelligible and perfectly common-sense truism. It would have seemed only a fair and simple act of ordinary patriotism to have solicited from among the Royal Academy body of artists, designs at least for the whole of the proposed painted windows, for the mosaics, and for a painted ceiling and walls. This is not merely to employ an

English contractor or decorator, or manufacturer of mosaic or glass, to do the manual work, and as a matter of business, but to help to realise the idea of employing in the best and noblest place the very best and most able men and artists. Some there are who must surely sympathise with this proposition, and agree that thus much *ought* to have been done. But what *has* been done? If the curious spectator has been surprised, as we feel sure he must have been, with the strange sight of the new organ and the scaffolding which supports it, and the iron girders which will help him to mount up to it, and the common oil paint which hides the stone walls and narrows the dome, and if perchance he hear, or even find, the old organ, and asks but to discover, may be, that the screen has been sold for old timber, yet more, as I think, will such spectator be confounded and utterly dismayed by the sight of the *ceiling* of St. Paul's now in course of being "decorated." To describe it would be impossible, or even to illustrate it by a woodcut, however carefully drawn; the idea can only be conveyed to those who cannot go and see it by the simple statement of the plain facts—that each circular panel (one only is as yet completed) of the ceiling of the east end of this building is painted in *imitation of mouldings* and sunk panels! No one can see such work as this nowadays in a common music hall or new theatre, or even smart public-house, the mere work, as work, being as bad as the design for it. Let no one who can go and see this specimen of decorative art take this statement on trust, and let him take good care to remember where he is while gazing at it—in St. Paul's Cathedral! Now, I think that even Mr. Penrose will allow this much, that when Sir Christopher Wren, the architect of this noble building, designed this ceiling and left these circular panels quite flat and plain, he intended them to be painted, *i.e.*, by a *painter* of some kind or other, and that such painting should consist of figures representative of some action or other, or illustrative of some sacred story. Surely he would have said to Rubens or Raphael or Angelico, "Go *you* and paint that round panel." This was the policy of Julius II. when the ceiling of the Sistine had to be "decorated," and of Leo X. when he found work for Raphael in the Vatican; and of our Charles II. when the Whitehall banqueting-room needed decoration; and it really seems to have been the way universally in the times that are gone by for those who employed art labour of any kind to find out, as if by instinct, the best men of their time, and then to employ their artistic skill and genius in the execution and decoration of the best and greatest works. We seem almost to reverse all this, and our painters expend all their time and talents in providing for the exigencies of the drawing and the dining-room. Cathedrals are either too large or too small for them, and are left to the mere tradesman and manufacturer of art.

To do thorough justice to this important subject would in effect be to write a specification for the entire restoration of the whole cathedral, and I have but space to hint at but one or two needful things. Confining ourselves therefore to the *roof* for the present, we may ask, Is it not a mistake to *gild* ornamental details? Round the circular panels, now so spoilt, Wren with great judgment designed some admirable ornament sunk within bounding mouldings; this has all been brightly gilt, so that the beauty of the details is lost by bright metallic lights and reflections, pretty enough in themselves, but destructive of the modelling of the ornament. This will be plain to anyone who looks at the capitally cut keystones of the arches under the gallery of the dome, where all the fine carving is completely lost under the coat of gilding so injudiciously put over it all, the high lights and bright reflections killing the sculpture. I think it may be laid down as a general and certain rule in artistic decoration, that the metallic gold in an interior should be confined to flat surfaces, to plain mouldings, and to very small ornaments, as where the moulding itself is cut into. The groundwork, for instance, of these circular panels before painting might have been of burnished gold, the figures on it, however quaint or natural, telling from the floor of the church with perhaps a truer force and effect than the simple painting of Rubens in the Whitehall ceiling. The three-cornered panels which make up the space between the circular centre panels and the four semi-circular arches which support them would be of course treated in like manner, and be made parts of the same composition. Surely this subject is worth a little more reflection before the whole roof is covered with "decoration" inferior to good papering. Thus, as it seems to me, there are in St. Paul's three things to be done; first, the whole of the wretched stone-coloured paint to clean off from the walls, thus to make visible and evident the colour of the stone and the real nature of the material of which the building is composed, and at the same time to improve and perfect the sound of it. Secondly, to replace as far as possible the stalls and organ loft and organ, and the old arrangements of the sanctuary or choir, and thus to preserve the idea of the church and the evidence of the motive of its building. And, thirdly, the stone surface being all visible, to decorate the interior bit by bit, and gradually and at the same time help the art of the age and country by giving the *painting* of it to painters—not, it is true, to Buonarroti and Raphael, or to Correggio or Rubens—for the time has not produced them or such as them—but to those whom it *has* brought forth, and in part at least helped and nourished—to Millais, Hunt, Dyce, and others such as them, and take the work out of the hands of mere tradesmen and art manufacturers of coloured glass and decoration. It is to be feared, however, that we have but very faint means indeed in this country of forming even a feeble judgment of what a *painted* building means, for with the solitary exception of the before mentioned ceiling of the Whitehall chapel, there is no building in London coloured by a *painter*, or rather, as we ought to phrase it, an artist-painter. There are plenty of "decorated" buildings coloured all over from roof to pavement, but such work does not and cannot rank higher than paper hanging. Rubens' painted ceiling will give some idea of what such splendid and magnificent work is, and a restored St. Paul's is worth a like effort.

C. B. A.

ASSOCIATED ARTS' INSTITUTE.

AT the usual fortnightly meeting of this Institute, held on Saturday evening, the 14th inst, Mr. A. H. Wall, vice-president, in the chair, Messrs. Charles Hazard and R. G. Box were duly elected members. R. Soden Smith, Esq., M.A., F.S.A., of the Art Library, South Kensington Museum, then read a paper—

ON SOME PHASES OF ORNAMENTAL ART CONSIDERED IN RELATION TO ETHNOLOGY.

During the last session of the Institute, the author read a paper "On the Ethnology of Art," in which he advanced the theory that all art was referable to three classes—viz., instinctive, intellectual, and moral or spiritual art, answering to the degrees of proportional development among the various races of mankind, of man's sensuous, mental, or moral nature. Instinctive art is the subject treated of in the present paper. Though the term "instinctive" cannot wholly be applied to any effort of the human mind which results in artistic feeling, it is the most expressive word the author can use. Architecture has been styled the parent of decoration, and justly so, in a general sense; but decorative art exists where architecture is unknown, and in countries where such architecture as there is is obviously subsequent in introduction or invention to the art now under consideration. Architecture is developed by civilisation, but instinctive art exists where civilisation has not appeared. The aim of such art cannot, therefore, be high; it occupies itself with surface decoration, not as subordinate to, and enhancing the effects of, sculpture and painting, but as the only art known, and, therefore, primary, instead of, as it should be, secondary. Instinctive art does not seek to interpret the aspects of external nature and translate them into a language intelligible to other men; this is the aim set before the landscape painter; it does not seek to reveal the story of human life or betray the secret springs of human action: this is part of the magnificent field open to the history painter. Its work is lower than this. The objects that surround daily life, the utensils of daily work, these are felt to be wanting in something beyond mere utility—something that will in no way hinder their use, something to be superadded to them for the satisfaction and rest of the eye. The results produced by this yearning after ornament are what the author calls "instinctive" art. Though each art is mainly traceable in efforts to decorate surfaces, it also influences form and among certain nations exceeding grace of curve and outline follows from an innate perception of the harmonies of form when the workman has materials sufficiently yielding—a perception analogous to that possessed by many of number, time, and tune. Within its own necessarily confined sphere, instinctive art may attain a perfection appropriate to each phase of art, besides that completion of the whole, that highest perfection which would result were the efforts of all three (instinctive, intellectual, and moral) arts united in their utmost development. The lower perfection (if the phrase is allowable) is gained most readily by instinctive art. It seems to be devoid of the hesitation and embarrassment incident to reflection; it works with a security of reaching its more lowly aim, and with a recklessness unknown in the highest art. Its nature is sensuous; it originates merely in the gratification of the sense, and begins and ends its appeal to man by pleasing his eye, as in colour or form, and satisfying his sense of touch, as in the small diaper on a savage's paddle, giving him a more secure hold. All art (the statement is here a truism) strives to appeal to make itself felt by some special quality or aspiration of man's nature. Instinctive art is not symbolic, for it does not address itself to the intellect; it is not truly æsthetic, for it does not stir the emotions. Its appeal is to man's lower nature. Its limits are best noted by observing its failures. While it confines itself to the outline of a club or the prow of a canoe, to the distribution (with an almost unerring sense of fitness) of a carved diaper, to the disposal in admirable balance of the colours on a chequered mat, to the enriching a surface with the most complex gold filigree or covering it with interlacings almost too minute to disentangle, success follows; but when attempts are made to realise animal or human forms the result is inevitably grotesque failure. The latter subjects of art belong to a nobler range and require the development of higher faculties to handle them safely, and it is therefore observable that instinctive art is often faulty among races of high organisation. Instinct in them is partially superseded by knowledge, and knowledge is not perfect. Instinctive art is limited wholly to conventional forms, whether in the round or the flat. The invention of these forms is probably the result of general as well as particular impressions made by the aspects and objects of external nature acting on certain innate faculties of the mind. For example:—The sense of direction is innate; there is no doubt in the mind about straightness; also, certain curves, as that of an egg, may please or even satisfy the eye. Such a curve is instinctively brought into relation with the innate notion of straightness, and thus an element of ornament is acquired. Again, the play of light among foliage or its glow over a wide landscape makes an impression more or less intense upon the mind. The sense of colour is an instinct with some races, notably with those living in tropical lands, is roused, and finds expression for itself, not imitating any particular object, but striving after a remembrance of the general impression in the combination of the most varied or the most gorgeous tones within their observer's knowledge or reach. Instinctive art in its primary expression deals wholly with forms that have no exact counterpart in external nature; it passes its limits when it strives after direct imitation. In form, its merit is due, first, to keeping with absolute certainty in view the use for which the object is intended, thus obeying a primary law of construction; secondly, to a perception (innate among some races, traditional among others) of the lines which, while se-

curing and furthering use, will most thoroughly satisfy the eye. In surface ornament its merit is due to the complete subordination of the ornament to the general form—to its suggestion of additional excellence in the object decorated, as solidity, toughness, or strength. The defects of such art are its limited range and the low order of faculties to which it appeals, neither influencing the intellect nor moving the heart.

Instinctive art amongst the races ethnologically classed as Malayan (New Zealanders, South Sea Islanders, &c.) is exemplified in collections of weapons and implements and utensils used by those races. The diapers woven in matting made by half-civilised tribes are often excellent examples of instinctive surface decoration. The patterns are geometrical, and the colours few and simple, and the effect is produced by the nice sense of proportion with which they are adjusted. The Chinese (the great representatives of the Mongolian tribe) seem incapable of conceiving moral or spiritual art, and intellectual art is scarcely developed amongst them. It seems doubtful if it is at all indigenous. They are constructors and builders, but can scarcely be called architects. Their instinctive art, though remarkable, is not pure, being mingled with efforts more or less abortive to attain to intellectual art, which their mental organisation prevents them comprehending. Their surface decoration is often marred by the introduction of ill-conceived elements. This especially applies to carving in relief. Scarcely an example, apart from colour, is quite satisfactory. In open work decoration the junction and combination of lines is so strange as to deprive the eye of repose; the spring of curve from curve is often not tangential; and a singular effect (which the author prefers to call Chineseism, for want of a more expressive word) separated Chinese art from that of all the "outer barbarians." With respect to colour, the instinctive art of the Chinese is instructive and admirable. They are colourists of remarkable skill, though surpassed by the Japanese, also a Mongolian race. Colour, as used by these nations, is unlike anything else in the world. Its chief characteristic is its dependence on secondaries and tertiaries, and in the use of some of these (as pale green, pink, and a broken blue) they are unsurpassed by any ornamentalists. They understand the application of the most vivid red, yellow, and the brightest white, but these are applied only in very small quantities in proportion to the broken colours. By the magic of colour the Chinese harmonise the discordant elements of form which intrude into their compositions and conceal errors or failures that would otherwise be fatal. In considerable surfaces of one tone their management of colour is admirable. The senseless uniformity of hue which mars the effect of many a piece of Sévres is skilfully avoided by the Chinese potter. His colour on a vase deepens and ripens in parts, as the sunny side of an apple or cherry, and it palpitates, as do the hues of nature. The source of this effect is at length known to, and sought to be realised by, English and French potters. The sooner it reaches the Saxon potters the better will it be for Dresden. Among the Celts (a race higher in the scale of humanity) instinctive art was developed in the highest degree, while, at the same time, no advance whatever was made by them (while unaffected by foreign influence) in the direction of intellectual art, and while only formless or uncouth efforts, as far as we know, were made in the direction of moral or spiritual art. The Celtic race unmixed does not appear capable of rising to the higher order of art: its conception, much less its realisation, is not within the scope of their powers; but their singular delicacy of touch and flexibility of hand may aid well in carrying out the thoughts of minds more gifted with art capacity. Amongst the Celts of Great Britain, especially of Ireland, the remains of their art are the most remarkable. There are two special directions in which the Celts have displayed their proficiency in instinctive art—viz., metalwork and the illumination of manuscripts. In both these the extraordinary skill with which surface decoration is managed will well repay study, always bearing in mind that it is only another development of that art which the New Zealander or the Papuan displays on his club or his canoe—an instinct or a tradition antecedent to civilisation. If spoken of as excellent and commended as unsurpassed, it should be remembered that it can in no wise appeal to those nobler faculties of the mind which are moved by the sublimity of architecture, the symmetry of sculpture, or the pathos of painting. The author entered at considerable length into the details of Celtic metalwork and illuminated manuscripts, which, from want of space, we are obliged to omit.

A short discussion ensued (Messrs. R. Phene Spiers, Holyoake, G. R. Redgrave, and Lewis Day being the speakers), and Mr. Smith having briefly replied on the different points raised, and a vote of thanks having been passed to him, and another to the various persons who had contributed art objects on the occasion of the late *conversazione*, the proceedings terminated.

THE NEW OPERA HOUSE.

ON Saturday last the officers and a large number of the members of the Architectural Association visited the new Her Majesty's Theatre, Haymarket, now in course of re-erection, and were conducted over the works by the architects. The roofs were first visited. Those of the auditorium, amphitheatre, and stage are flats, covered with No. 16 Vieille Montagne zinc, laid on Croggon's patent hair felt and inch-and-a-half boarding. These zinc flats will be the largest in London. The roofs of grand staircases and saloons of dressing-rooms and of carpenters' shops and painting-room are constructed with iron principals, covered with board and slate. The stage, amphitheatre, painting-room, and carpenters' shops are lit by skylights. The roof of auditorium is carried by four braced wrought-iron girders. These girders are 86ft. in span, and about 7ft. deep in the centre, and weigh about twelve tons each. There are no rooms over the auditorium or stage, the painting-room being placed by the side of the stage, and the carpenter's shop over the dressing-rooms facing the Haymarket. Angle iron ribs form the framing for the dome, and elliptical beams are suspended from the roof and secondary girders. The ceiling is to be formed with half-inch boarding. The next things noticed were the wrought-iron cantilevers for carrying the boxes. Those in the centre of the house have a projection of 12ft. from the columns, the object being to form open tiers of boxes to be used when required for dramatic purposes. There are four full tiers of boxes and a half-circle tier. The length of the auditorium is a few feet less than in the old house. This is partially occasioned by the increased depth of the centre boxes, and partially by the stage being made deeper. The height will be about 10ft. greater than that of the old building. Attention was next directed to the entrance hall and grand staircase. These, in the old house, were placed at the back of the auditorium, but in the new building they have been placed at the north-east angle, next to the Haymarket, the grand staircase being carried up to the half circle tier of boxes and communicating with each tier, instead of stopping at the grand tier level, as in the old house. A stone staircase of communication between all the tiers has also been provided in addition to the grand staircase. The gallery staircase and the principal staircase to the amphitheatre stalls are provided at the north-west angle of the building, communicating with the arcade. There is also an additional staircase provided for the gallery leading to the grand stairs, to be used in case of fire. All parts of the auditorium are in communication with at least two staircases. The passages to the stalls and pit lead out of the principal entrance hall. All staircases throughout the house are of stone, and all passages or landings are constructed on Dennett's patent concrete arches. The royal box has a separate staircase, with retiring rooms, &c., complete. The stage is much increased in size, being about 56ft. in depth by 95ft. in width, and, in addition, there is a scene dock on the east side, under the painting-room floor. The original stage of the old house was about 34ft. by 90ft. The roof over the stage is constructed of braced wrought-iron girders about 56ft. in span. The painting floor is on the east side of the stage, and measures 71ft. by 21ft. It has a cut in the floor on one side for lowering the painting frames, and one on the other side for lowering the scenes on to the stage. The basement under pit floor is devoted to the storage of "properties," &c. The remainder of the building is devoted to offices and dressing-rooms. The only wood floors throughout the building are the floors of carpenters' shops and the floors to the boxes and gallery. Everywhere else the floors are constructed on Dennett's concrete arches, including the whole of the basement floor. A massive wall is carried up over the proscenium. The fronts of the boxes, as well as the surface of the ceiling, will be boarded, and there will be no decoration in relief, so that, as far as possible, the new theatre may possess the same excellent acoustic qualities as its predecessor. The works are being carried out by Messrs. G. Trollope and Sons, from the designs and under the superintendence of Mr. Charles Lee, assisted by Messrs. Lee, Brothers, and Pain, of 3, Whitehall-place, architects, and they are now in a very forward state, and fast progressing towards completion. There is no doubt that the building will be completed in March next.

The members of the Association having expressed their thanks to the architects for their kindness in showing them over the works, the latter signified their willingness to do so again when the works are nearer completion.

CLOCKS, AND THE STRUCTURAL ARRANGEMENTS MADE FOR THEIR DISPLAY AND PRESERVATION.*

THE author said he approached the third and more specially practical part of his subject with considerable diffidence, but he felt that some member of his profession ought to break silence on the subject of architects' alleged ignorance of the obvious requirements for satisfactorily incorporating turret clocks with ordinary structures. He was first led to think of this subject by finding out practically the trouble and expense incurred in making arrangements for the fitting up of a large turret clock in a building in which no special provision had been made for its reception. The clockmaker understood his clock, but he could not realise the particulars given him of the building; Mr. Wyatt understood his building, but could not realise the particulars given of the clock. The consequence was far too much friction before the two working parts could be brought to go well together, and that friction would have certainly proved prejudicial both to the clock and the building if the knot had not been cut, rather than untied, by making a new building specially for the clock, instead of endeavouring to fit the clock to the existing structure, altered to accommodate it. The experience so acquired induced the author to pay some little attention to the matter, and he soon found that the want of sympathy and ready understanding of one another's difficulties which had existed between the clockmaker and himself was by no means singular. In Mr. Charles Frodsham's admirable report on Class XV. of the Exhibition of 1862 (Horological Instruments), he met with the following passage: After commenting on the work of a clockmaking firm who had lessened the value of an otherwise excellent instrument by using too short a pendulum, the reporter observed that the makers in question alleged as a reason that "they seldom found room for a greater length, which we all know is too often the case. Architects generally forget that a clock is a very large piece of machinery, requiring room and fall for the weights—100ft. for a very large clock, and from 30ft. to 40ft. for a small one. Turret clocks may be made well and cheaply at the same time; it only requires three or four good models, because it is the large repetition of the same models that enables the manufacturer to work cheaply and economically." Armed with this expression of Mr. Frodsham's opinion the author set himself to work to tabulate the items of information which it seemed to him most essential that the architect should have at hand for consultation when engaged in designing any portion of a structure destined for the reception of a turret clock, and then endeavoured to collect the requisite data for filling it up. In this he had been unsuccessful, owing mainly to a sudden domestic affliction which befel the gentleman on whose assistance he had most relied. He thought it well, however, to now bring forward the tabulated form he had prepared, with all its blanks, in the hope that some intelligent clockmaker would fill it up or improve upon its form (See next page.)

With reference to the kind of information the author desired to collect for the guidance of architects, in his reply to an application to him for aid, Mr. Frodsham remarked:—"I scarcely know anything of the kind that is more wanted. At present there is no uniform rule of constructing clock rooms, proper channels for the fall of the weights, room for bells and bell hammers, and a score of other provisions. Thus the construction of a turret clock is rendered very expensive. I

QUERY.—Most convenient situation for run of clock weights?—In 1-dial? 2 dial? 3 dial? 4-dial clocks?

QUERY.—Most convenient position for swing of pendulum below floor of clock chamber in 1 dial? 2 dial? 3 dial? 4-dial clocks?

It is assumed that the dimensions given for the clock-chamber will be sufficient to allow a man to get at all parts of the clock if he can pass up through the floor of the chamber.

N.B.—If this table should be drawn up on the basis of clocks with single dials (and not illuminated) it would be well to note differences due to additional dials, as for two instead of one, four instead of two; or for illumination, if through transparent dials, or for chimes if added.

consider the English marine chronometer a marvel of cheapness, particularly when the various adjustments must be done by an educated scientific man; yet, from the repetition of one or two good models, they are constructed in large numbers at a tithe of the cost of a few years ago. But in turret clocks nearly every order ignores previous, and involves fresh arrangements and new casting patterns." While acknowledging that this might be partly attributable to the architect's ignorance, and the requisite structural wants for good clock accommodation, the author was bound to notice how little effort had been made by horologists to remove that ignorance. One would have thought that to frame a few simple rules for the guidance of architects would not have been a very difficult matter, and yet he altogether failed in meeting with anything of the kind. A little information, and but little, was to be gleaned from Mr. Vulliamy's old pamphlet "Some Considerations on Public Clocks," and rather more from Mr. Denison's treatise, but both were eaten up with personalities and quarrelling. The first duty devolving upon the architect practically would be to advise his client as to the propriety of having a clock at all; upon its best situation if determined upon; as to its suitable size, quality, altitude, and connection or not with bells or chimes. There were circumstances under which the striking was more important than the time-showing, and *vice versa*. The next point the architect had to consider was the relation of diameter of dial to height at which the dial might have to be placed, or conversely, to fix the height suitable for the display of a dial of any given size. The old empirical rule of 1 to 10 had been held to be a safe one by most writers on the subject, although the tables of heights and diameters of leading dials given by Mr. Denison and Mr. Vulliamy by no means uniformly sustained this view. The former considered 1 to 10 to be a minimum, and on a comparison of the best-looking and best seen dials and clock towers he (Mr. Wyatt) was of opinion that 1 to 8 would be a juster proportion than 1 to 10. It was imperatively necessary that the spots marking the positions of the figures on the dials should be real spots, whether the figures were distinct or not, and that the hands, both in form and colour, should offer the strongest possible contrast to the dial. Mr. Denison had many excellent remarks on the subject, but they might be summed up in the above. It was a common practice with the earliest clock faces to cover them with a projecting hood or roof carried on bold brackets. The author was by no means sure that this was a commendable course, since the hood was apt to throw a shadow across the clock face, rendering it extremely difficult at a distance to realise the position of the hands during the busiest hours of the day. It was far preferable to select enduring materials, such as stone, slate, glass, majolica, or enamelled iron or copper, the colours and gilding of which had been fixed by vitrification. In such case rain cleansed without injuring, and hoods of any kind might be dispensed with. In designing diapers or ornamentation for clock dials, care should be taken to keep straight lines out of the pattern, since they had a tendency to hold the eye and distract it from seizing the position of the hands at a glance. The best mode of ensuring the contrast pointed out as indispensable was to make the dial dark and the hands and spots for the figures light, or *vice versa*, and in colour, that of the hands and spots for figures should be complementary to that of the average tone of the dial. It was well not to make a violent contrast between the periphery of the dial and the stone or other framework in which it was set. If this was neglected the eye would run round the exterior before settling on the clock hands. There were three particular points of the architect's practice in respect to the accommodation of clocks in lofty positions, as in upper chambers of towers, in which he would come across dilemmas which would occasion him some trouble. For instance, firstly, he might provide for the support of the heavy clock frame rigid beams of iron or comparatively elastic beams of timber. The advantage of the rigid beams was that the clock would go better in fair weather; their disadvantages were that they communicated instantly to the works every shock, oscillation, or vibration experienced by the tower in stormy weather, and what these amounted to in cases where the tower was slight in its construction, those only could realise who had remained amongst the bells when a gale had been blowing. In the case of the wooden beams the advantages and disadvantages were exactly reversed. The prudent course would be found to consist in providing rigid iron beams for large clocks in very stable towers, or when the clocks were not raised to any great height from the ground, and trussed timber in other cases. Trussed timber beams were better than untrussed, since, however strong the untrussed beam might be, it would in time acquire a "*set*" under the permanent load which might disturb the going of the clock, altering the position of the going part with reference to the dials. Secondly, the architect might provide many air openings for the ventilation of his clock or none. If he adopted the first course, he would leave his clock too much exposed to change of temperature, and the admission of dust and even wind, dirtying and deranging the best mechanism. If he adopted the latter, damp would form and prove nearly as prejudicial. His good judgment, if exercised, would lead him to avoid either extreme, and either to ventilate by derivation, as from a lower thoroughly ventilated chamber through to an upper thoroughly ventilated chamber; or, if direct openings were made from the exterior of the building to the clock, by a system of filtration, in which inclined louvres (as the blades of a Moore's ventilator opened but little) stopped wind or violent draught, and in which wire gauze or finely-perforated zinc arrested the passage of dust, blacks, and other impurities to the works of the clock. Thirdly, for the preservation of the movements from the effects of atmospheric changes, and for preventing the too speedy congelation and clogging or drying up of the oil or other lubricant used, the architect might deem it wise to enclose his clock in a wooden case, to which, however, the following objections existed, viz.:—enhanced risk of destruction in the event of fire; darkness, increasing the difficulty of oiling and repairing; and such an encumbering of the clock chamber as made examination of the state of the clock a considerable trouble, leading to neglect and to consequent rapid deterioration. His best issue from this dilemma would be found in a spacious case of wood, and the enclosure of the movements itself by means of lifting or sliding glazed sashes. Care should of course be taken to ensure that if a rope should break, letting fall a heavy weight, it should either have a clear run to Mother Earth, or be arrested in its downfall by a safe and satisfactory buffer. For this Mr. Denison suggested that "there ought to be a box of at least 2ft. of dry sawdust and shavings, with a cover of wood, or, still better, of stone for the weights to fall on if a rope breaks. Otherwise a heavy weight will go through any number of tower floors, and into the vaults below, as has sometimes happened."*

NEW PATENT VENTILATING CORNICE.

NEW methods of ventilation, differing little in application and not at all in principle from each other, are by no means rare. Few survive the test of experience, principally on account of the tendency of most of them to create that terror to all cold-catching Englishmen—a draught. A new plan has been introduced by Mr. William Potts, of Handsworth, near Birmingham, which at any rate avoids that evil, and seems to have many advantages. Acting on the generally admitted rule that the upper part of a room is the proper place for the admission of fresh air, he uses the cornice as the means of its admission. The cornice is formed of metal—preferably of tin or zinc—with ornamental perforations. It is easily moulded into any form, and may be painted, gilt, or decorated in any way, and can at any time be washed or renovated. It is, moreover, almost, if not quite, as cheap as the ordinary plaster cornice. By dividing the cornice longitudinally about the middle the patentee forms separate air chambers, the hot air escapes by the ornamental perforations in the upper members of the cornice into the channel at the back of it, all round the room, and from thence passes into the chimney or other flue, through a valve or valves opening at will; the cold air, being admitted into a channel at the back of the lower portion of the cornice by a valve or valves communicating externally, or with the hall or lobby, or both, enters the room without draught by passing through perforated zinc or gauze, becomes warm in descending, and expedites the discharge of the vitiated air.

Existing plaster cornices can be easily and inexpensively adapted to the new system, and where architects still prefer to use plaster the effect can be obtained by the usual mode of wood framing. The valves which control the egress and ingress of the impure and fresh air are entirely under the control of the inmates of the house, and can be opened and shut when desired.

We are informed that Mr. John Dale, the architect, is fully convinced of the value of the invention, and has expressed his intention to use it in every room in a very extensive convalescent hospital about to be erected from his designs.

The ventilating cornice is at present fixed at Messrs. Hart and Son's, Wych-street, and at Messrs. Brown and Co.'s, 93, Newgate-street. At the latter place is the best effect produced—from an ornamental point of view. Mr. Brown courteously intimated to us his willingness to show and explain its principles and construction to parties interested in the subject, and we recommend such to see it and judge for themselves.

THE WEST LONDON HOUSE PAINTERS' ASSOCIATION.

ON Thursday week an interesting lecture was delivered by Mr. M. Digby Wyatt, on the "History of Decoration by means of Colour," to the members of the West London House Painters' and Decorators' Mutual Improvement Association, at the St. John's Schools, in Kirkman's place, Tottenham-court-road. The chair was taken by Mr. Edward Hall, F.S.A., and there were present Mr. Crace, the Rev. H. Solly, and others. Suspended on the walls were numerous drawings by Mr. Wyatt of buildings in Italy, and details of

* To be continued.

decoration, as well as specimens of textile manufactures exemplifying Persian, Chinese, and other methods of ornamentation. The lecture, besides treating of the Eastern, Egyptian, Greek, Roman, and later Italian, and the French styles, explained the principles of conventionalism and imitation in decoration, the latter of which was characterised as dangerous, although it embodied the perfection to be attained; whilst the former had the attribute of propriety, and, being more easy of attainment, had come first in the progress of art, and even now was in vogue in some countries. The value of an attention to style was also shown. One characteristic of each style was the harmony that it had in itself; and this harmony should not be omitted as a feature when new productions were required. The audience was afterwards addressed by Mr. Crace, Mr. Solly, and the chairman, who urged the importance of establishing classes for instruction in drawing and other requisites of the house-painter's craft, and who also adverted to the necessity for securing greater durability in painter's work, especially where costly decoration was attempted.

INDIA MILL, DARWEN, LANCASHIRE.

THIS building, of which we give an illustration, is the one in which the art exhibition of August last was held, and presents several noteworthy features, one of these being the largest, if not the highest, chimney shaft in the world. The mill itself is 330ft. long, 99ft. wide, 90ft. high, and contains six stories. The engine house is 80ft. by 28ft., the engine bed containing 20,000ft. of ashlar. The boiler house is 100ft. by 75ft., and accommodates ten boilers. There is also a cotton shed and twist warehouse 100ft. by 80ft. The engineering and mill gearing is being executed by the trustees of the late W. and J. Yates, of Blackburn, all the entablatures and pillars being carefully got out to architectoral proportions, an unusual thing in machinery. The total height of the chimney shaft from the bottom of the foundations to the top of the iron cresting is 310½ft., and from the ground line 300ft. The base is of solid ashlar, 29ft. square at ground line, and 42ft. high. The massive stone cornice to the base is 35ft. long on each of the four sides. The shaft itself is built with red, white, and black bricks, with sand grit-stone dressings, and is 24ft square, and built perfectly plumb. The walls are 3ft. thick at top of stone base, reduced by "set-offs" on the inside to 23in. at the commencement of main cornice, which is 255ft. above the ground. Many of the stones used in this cornice weighed as much as five tons each, and were hoisted by steam power. The balusters surmounting this feature are of cast iron, as also are portions of the four vases at the corners. The crown mould of the cornice at the top of the shaft projects more than three times as far over the wall as it rests on it, and was kept in its place by iron cramps until the cast iron cresting was fixed upon it. This cresting contains about 20 tons of metal, and is composed of more than three hundred castings. There is no bolting nor any particle of wrought iron in this portion of the work, the parts being kept together by slots and lugs. The whole weight of this cresting stands upon the brickwork, and keeps the upper stone cornice firmly in position. There is an interior and totally independent shaft, 180ft. high, to prevent the great heat from the boiler furnaces subjecting the wall of the outer and main shaft to unequal expansion and contraction. Mr. Ernest Bates, of Manchester, is the architect, and the whole of the work has been done by day work by workmen under the superintendence of Mr. Robert Edwards, clerk of the works, no contractor being employed.

THE FEMALE SCHOOL OF ART.

ON Saturday afternoon prizes and medals were distributed to students of this School of Art who had excelled in drawing, painting, designing, and art literature. The students and their friends assembled in the lecture hall of the University College, Gower-street, which was filled to overflowing. Mr. Layard, M.P., presided, supported by Mr. M'Cullagh Torrens, M.P., Mr. Westmacott, R.A., Mr. S. Poole, Miss Gann, the superintendent of the school, and numerous artists.

Mr. S. Poole read a lengthy report, which stated that there were 108 students on the books; 80 students had sent up works for inspection to the annual examination of the drawings at South Kensington, and fourteen had obtained third grade prizes of books, the works of eight students—Misses Banks, Clarke, Ellis, Hewson, Locke, Manly, M'Gregor, and Pocock—being selected for the National Exhibition. Of these students two obtained National Queen's Prizes, and one a National Bronze Medal. Three students—Misses Dixon, A. D. Webb, and M. W. Webb—obtained certificates of the third grade (these certificates being of a much more advanced character than the second grade). A prize of five guineas, presented by Mr. J. H. Walton, for anatomical studies, was awarded to Miss Alice Blanche Ellis. Various vacation prizes, presented by Mr. Henry Bicknell and Mr. J. H. Walton, had been awarded, the first to Miss Julia Pocock for a study from the life. A prize of five guineas, presented by Mr. John B. Allcroft, and a second of two guineas, presented by Mr. L. R. Talpy, for the best essay on the uses to which the School of Art could be put, have also been awarded to Miss E. Toulmin Smith and Miss Isabel Berkeley. The Queen's Gold Medal was awarded specially in the department of applied design to Miss Sarah M'Gregor, for designs in lace and church decorations; the drawings by the student were submitted to the Queen's inspection, who graciously purchased a study of flowers as a mark of her Majesty's approbation. The examiners for the Queen's medal were Charles Landseer, R.A., Sir A. Hart, R.A., Henry O'Neil, R.A., and J. Holland. Alice Alfrida Manly, late pupil teacher in this school, who last year carried off the Queen's Medal, has been admitted a student of the Royal Academy. The report having been read, the prizes were distributed to the successful candidates; and, on presenting them, the chairman bestowed a few words of encouragement and laudation on each of the fair recipients. At the conclusion of the presentation Mr. Layard addressed the assemblage on various art topics.

Mr. M'Cullagh Torrens, M.P., in addressing the school, asked the students to avoid "the finical." He thought it was the besetting sin of our time to be too minute and too anxious to do something that was perfect in itself. There was also a tendency to make the objects of art too small—they should rather draw large than diminutive. He moved a vote of thanks to the council of the University for the loan of the lecture-hall, and for the interest they took in promoting their studies. Mr. S. Poole seconded the proposition, which was carried; and a vote of thanks to the chairman terminated the proceedings.

MEDIÆVAL IVORY CARVINGS.

WE furnish our readers this week with a lithographic drawing of mediæval ivory carvings, taken principally from the collection at the South Kensington Museum, where a special department is devoted to the exhibition of such and similar works of art.

Nos. 1 and 3 are abnormal animals. They make up the spandrels of circular mirror cases, and are of fifteenth century workmanship.

Nos. 4, 5, 6, and 7 are carved, engraved, and cement-filled plaques on the cover of a bone box. They represent the various poses, &c., of the common Morris or pseudo-Moorish dancers of the fifteenth century, and are taken from a casket of French execution.

Nos. 8 and 10 are twelfth century Byzantine borders, and are exceedingly playful and characteristic in their interlacings.

No. 9 is a cross of very simple and elegant proportions, carved in low relief on a Romanesque panel.

No. 2 is by a draughtsman of the thirteenth century, carved out of walrus tusk and labelled, "The sign of the Zodiac for the month of January;" but we would suggest, however, that more probably it is a representation of the preparation for "a sacrifice." This example, now in the British Museum, is very boldly cut, the figures being almost entirely detached from the ground.

From the Egyptians downwards we find the use of ivory universal in every age of art. Several very fine specimens of Egyptian, Assyrian, and old Indian ivory carving are to be seen in the Louvre and our own Museums. In Scripture, too, we find mention made of ivory thrones, beds, and palaces, and if we can credit the account of Strabo and others regarding the colossal statue of the Olympian Jupiter at Elis, made of ivory and gold by Phidias—the Chryselephantine of the Greeks—ivory was then made much more use of than in modern times. The solid and compact nature of the material allows the artist to linger over and revel in his work, as exemplified in the minute delicacy of the Chinese carvings. To the mediæval European artist it must ever have been a costly material.

Ivory has this decided advantage, that where many fine art treasures of the precious metals have succumbed to the vicissitudes of the times, and found their way into the melting pot, it has been preserved owing to its value as a work of art and its inherent worthlessness except from an art point of view. In a temperate climate it may be considered as practically indestructible. The Assyrian ivories, when brought to the British Museum, were found to be much desiccated by time and dry atmosphere, but after they had been saturated with boiled ivory shavings they became as hard as the ordinary material. O. W. D.

SOCIETY OF ARTS.

THE 115th session of the Society of Arts commenced on Monday evening, when Lord Henry G. Lennox, M.P., delivered the opening address. After some introductory remarks Lord Lennox said—The first thing he would notice would have relation to the Art Copyright Bill, which would be again brought before Parliament during the ensuing session. With respect to technical education, he considered that the study of the pure sciences must be the true foundation of all valuable technical instruction. After referring to the school of naval architecture at South Kensington, which was, he said, sending into the profession a valuable body of young men, his lordship stated that he hoped the long-sought, for problem had been solved of the discovery of a chemical composition to prevent the fouling of ships. He regretted that Mr. Whitworth, whose munificent foundation of the only technical scholarships could not be too highly lauded, was not present to receive the gold medal, which the society had awarded him, and he went on to advocate the maintenance of art museums in great manufacturing centres. It was most important to set good models before the artisans. In 1750, when the Society of Arts gave premiums for success in art, they had no museum and no gallery by which to educate the artists. His ancestor, the third Duke of Richmond, then supplied them with a gallery of statues and objects of art. His lordship then alluded to the deplorable want of taste in the London streets and statues, and recommended that a committee of taste should be appointed to examine and report upon the Thames Embankment, with a view to its prevention from being employed in a manner contrary to good taste. He concluded by assuring his hearers that he would use his best exertions to promote their welfare. Mr. W. A. Gibbs was then presented with the gold medal of the society and 50 guineas, for his invention for harvesting corn in wet weather. Mr. Robert C. Kington was presented with a certificate for having obtained the greatest number of first-class certificates at the society's examinations. The Albert Gold Medal, awarded to Mr. Whitworth for his munificent donations for the benefit of technical education, was to be forwarded to Mr. Whitworth by Mr. Foster, the secretary. Upon the motion of Mr. Shaw, seconded by Mr. Seymour Tenlon, the thanks of the society were given to the noble chairman, and the business terminated.

A correspondent sends us the following letter:—Sir,—It appears to me that the study of the profession of architecture would be greatly facilitated to young men were they furnished with a list, by those in position, of the works most suitable as standard text books and references. Amid the vast sea of publications it is difficult, nay impossible, for the student to make the selection for himself, but were he guided by adequate authority as to which works are really useful he would be saved much time and unprofitable labour. It is not the *scarcity* of good books of which he has to complain, but a want of an authorised statement of their comparative usefulness. Let the Institute make a small and careful selection from existing works and publish it under their approval, and by doing so I am sure they would earn the lasting gratitude of the younger members of the profession.—X.

HINTS ON HOUSEHOLD TASTE.*

IN the preface the object of this work is stated to be "in a word, to suggest some fixed principles of taste for the popular guidance of those who are not accustomed to hear such principles defined," and it has reference to articles of furniture, house decoration, and other things of ordinary use which surround us in our homes. As most of our readers will acknowledge that a healthy art in any age or country will affect the design of articles of manufacture, and not limit itself to pictorial inventions or any other special department of taste, there can be no question as to the utility of such a handbook of household taste as this purports to be. Several antiquarian treatises of the subject of furniture have appeared before, and that by Monsieur Viollet le Duc is known to and appreciated by most architects; few of these, however, are addressed to the class of persons whom Mr. Eastlake seeks to reach, and the examples described in such works are seldom adaptable to modern requirements.

It not being for architects or artists that this work is intended, any criticism founded upon its not presenting in its pages special novelties to them is disarmed. The same reason explains the absence of all reference to the efforts of other professional men who have for some time been striving in the same direction, no great success having yet crowned their efforts to correct the public taste. Speaking generally, the strictures passed by the author upon the character of modern cabinet work and upholstery, though severe, are just. False principles and false taste are rampant. Still, seeing the direction in which the author would endeavour to lead his readers, it is impossible to forget that the Mediæval Court at the International Exhibition of 1862 contained works of merit by Messrs. Morris, Marshall, and Co.,

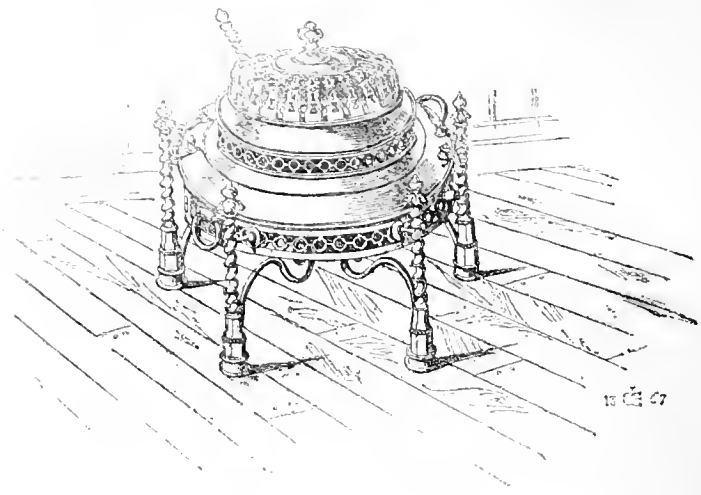
* "Hints on Household Taste," by C. L. EASTLAKE, Esq.

Burges, Seddon, and others, and various examples of the kind have from time to time been illustrated in the pages of this journal. In other styles also, several manufacturers have produced works which do not deserve to be classed with the tawdry rubbish described as so general. The grace of English furniture of no very ancient date is of marked merit, and some of our best artists and designers have left their mediæval love, and gone clean over to the camp of those who extol the relics of the days of Queen Anne. We ourselves, though heartily endorsing Mr. Eastlake's strenuous upholding of the common-sense principles which dictated all Gothic design, would commend to his serious study the delicacy and refinement of the furniture of the class we have referred to.

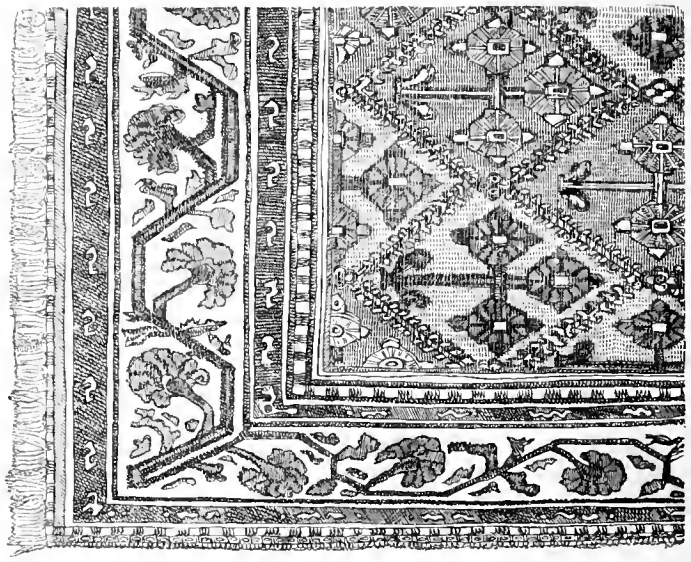
The volume is divided into twelve chapters, to which an introduction is prefixed. The first chapter is devoted to a description of the present character of street architecture, for the sake of comparison with which a clever illustration is given of a street in Nuremburg; we must own that the author has taken no unfair advantage by this selection, as Pugin is said to have done in his "Contrasts," for, with the exception of the church in the distance, we see nothing particularly picturesque in it, the houses being of very ordinary character. Surely Nuremburg or a hundred other cities would have afforded subjects more likely to press home this point.

The chief theme, however, of the work is the interior and not the exterior of houses, and Mr. Eastlake does not confine himself to criticisms on what exists, with lamentations after what has passed away; but side by side with capital sketches from old examples he sets some excellent and suggestive designs of his own to show what he would propose in their place. In the following passage he racily hits the blots of ordinary modern work:—

> And here, perhaps, I should astonish my readers if I were to state that there is no upholsterer in London at whose establishment good artistic furniture of modern date is kept on stock for sale, and yet such a statement would not be very far from the truth. For years past this branch of art-manufacture has been entrusted to those whose taste, if it may be called taste at all, could be no more referred to correct principles of design than the gimcrack decorations of a wedding cake can be tested by any standard of sculpturesque beauty. It may be urged, in answer to this parallel, that in the latter case it would be superfluous to apply such a test. Without even admitting this to be so (for in the best ages of art the commonest article of household use, down to the very doornails, had an appropriate form and beauty of its own), it is obvious that, although we may tolerate insipid prettiness in perishable confectionery, we ought not to do so in objects which become associated with our daily life, and which are so eminently characteristic of our national habits. There are few persons of education and refinement who do not feel interested in architecture, but I would ask of what use is it to decorate the exterior of our country houses if we are to permit ugliness within them; and ugliness we shall be sure to have if the choice of furniture is left to ordinary upholsterers. Indeed, their notions of the beautiful are either centred in mere novelty or derived from traditions of the Louis Quatorze period. That school of decorative art, bad and vicious in principle as it was, had a certain air of *luxe* and grandeur about it which was due to elaboration of detail and richness of material. Its worst characteristic was an extravagance of contour, and this is just the only characteristic which the tradition of upholstery has preserved. Our modern sofas and chairs aspire to elegance, not with gaily embossed silk or a delicate inlay of wood, but simply because there is not a straight line in their composition. Now a curve, especially of such a kind as cannot be drawn by artificial means, is a beautiful feature when rightly applied to decorative art, whether we find it as the appendage to an old Missal letter, or bounding the entasis of a Greek column. But a curve at the back of a sofa means nothing at all, and is manifestly inconvenient, for it must render it either too high in one place or too low in another to accommodate the shoulders of a sitter. The tendency of the present age of upholstery is to run into curves. Chairs are invariably curved in such a manner as to ensure the greatest amount of ugliness with the least possible comfort. The backs of sideboards are curved in the most senseless and extravagant manner; the legs of cabinets are curved, and become in consequence constructively weak; drawing-room tables are curved in every direction—perpendicularly and horizontally—and are therefore inconvenient to sit at, and always ricketty. In marble washstands the useful shelf, which should run the whole length of the rear, is frequently omitted to ensure a curve. This detestable system of ornamentation is called "shaping." It always involves additional expense in manufacture, and therefore, in avoiding "shaped" articles of furniture, the public will not only gain in an artistic point of view, but save their pockets.



No. 5.—MODERN SPANISH BRAZIER.



No. 6.—HEARTH-RUG FROM SCINDE.

The "Entrance Hall" is the title of the second chapter, and, to show what may be done with floors, illustrations are given of encaustic tile pavements, by Messrs. Maw. Of these, however, we think no very favourable selection has been made, for we notice in them the prevalence of an indifferent buff, while one ribbon border offends against a canon laid down in the text, "that there should be no attempt to indicate relief or raised ornament in the pattern." Nor can we say that we care for the example of mural decoration of Messrs. Heaton, Butler, and Bayne. The design for a hall table, by the author himself, shown in the illustration (No. 1), is far preferable, and by its simplicity and by the character of its structure and ornament serves to show the direction to which Mr. Eastlake would lead us in the way of reform.

Chapter III. treats of the dining-room, and contains some good remarks, but we fear that the author will fail in his endeavour to induce the public to dispense with their movable tables. The interesting old examples he gives were very suitable to the public halls for which they were designed, but would be most cumbrous for present household use A modern telescope table on four corner legs is, it is true, ugly and weak, but the expansive system is a great convenience and may be better treated. The old armchair from Knole, shown in the drawing (No. 2), is a pleasing example, equally suited to our own wants as to those of our grandsires.

In chapter IV. on "the floor and the wall," as an example of Oriental manufacture, and *apropos* of the advantage of a certain degree of freedom and irregularity of design as compared with the studied accuracy of English carpets, the sketch (No. 6) is given of a cheap hearth-rug, from Scinde.

Such carpets, laid upon parquetry floors, the author recommends as better and hardly more costly than the practice of covering up every corner of a room with Brussels carpet, which he inveighs against as a piece of modern folly involving waste of material and sacrifice of effect.

Chapter V. treats of the library, and the drawing-room forms the subject of the sixth chapter, and we think that the ancient examples of the furniture for the latter, given in the illustrations, far surpass those suggested for modern use; thus while we can hardly sufficiently express our admiration for the beautiful sofa from Knole, shown in plate 28, we confess we do not see the adaptability to its purpose of the drawing-room cheffonier designed by Mr. A. W. Blomfield. Sympathising with the author's desire to see good inlaid ornament substituted for the indiffe-

rent carving now in vogue, and appreciating his pretty sketch of an ancient example of the style of decoration recommended, we subjoin his remarks on the subject with the illustration they refer to.

Where an effect of richness is aimed at, two legitimate modes of decoration are available for wood, viz., carving and marquetry or inlaid work. For cabinets, coffers, sideboards, and other repositories of household goods, the wood carver's art has been successfully employed in the best ages of design; but it should be sparingly used for chairs, tables, couches, and in all situations where a knotted lump of wood is likely to prove inconvenient to the touch. It is a pity that marquetry should have fallen into such disuse, for it is a very effective and not necessarily expensive mode of ornament. It consists of inlaying the surface of one wood with small pieces of another, differing from it in vein or colour. These pieces may either be grouped in geometrical pattern or arranged so as to represent natural objects pictorially. The tarsia, or old Italian marquetry, was used for both purposes, and owing to the minute size of the inlaid pieces, was equally adapted for either. The woodcut (No. 3) is from an early Italian casket in the South Kensington Museum. The lower portion is of carved ivory, the lid being composed of ebony and ivory inlaid. It is probably of fourteenth century manufacture.

The seventh chapter is entitled wall furniture, and the eighth treats of the bedroom; the good design for a chest of drawers (No. 4) will give a sample of its contents.

The concluding chapters treat of crockery, table glass, dress and jewellery, plate and cutlery, all of which are well and fully illustrated with able sketches of interesting objects, from which we select the sketch of a modern Spanish brazier (No. 5) in the possession of Lord Mount Edgecumbe, at Cothele, with some remarks as to the prospects of art manufactures deserving of consideration:—

The future success of art manufacture in England must, of course, depend in a great measure on the taste of the public for which it is supplied; but I do not see how that taste is to recover from its present degradation until manufacturers begin to educate it by the production and display of goods which will bear the test of sound criticism. Museums and exhibitions of art treasures are useful in familiarising the eye with the appearance of objects which illustrate the taste of a former age. But it must be remembered that such objects are usually articles of luxury, which at any period would lie beyond the reach of ordinary means, and which in many instances were applied to some purpose that has long since fallen into disuse. In examining them, people are apt to forget that our forefathers were not all people of unlimited wealth, who could afford jewelled caskets, costly embroidery, richly carved cabinet work and plate, which would fetch ten times its weight in gold and silver.

In those early days there were, as now, households in which economy was an object. Pots and pans, wooden trenchers and three legged stools—articles, in short, far more humble in make and material than those which increased commercial prosperity has given to our present homes—were then required, produced, and sold at a moderate price. But it was not because they were cheap that they were necessarily ugly or ill fashioned. That contemptible kind of workmanship that is at once slovenly and tasteless because it may be showy and cheap, was not then in demand. The rich, indeed, spent more money, both on dress and objects of general luxury, than at the present day; but such furniture as be fitted the habits of ordinary citizens and country gentlefolks of that date was found in the homes of the middle classes more than two hundred years ago; and wherever it existed, we may be sure it was deftly and honestly made. Those examples of ancient handicraft which have reached our own time may well put to shame the efforts of modern smiths and cabinet makers, who work like machines, while their ancestors worked like artists and practical men.

We think the work is well-timed, and calculated to prove practically useful in spreading those true principles of ornamental art which we desire to see more widely understood and followed.

RAILWAY COMMUNICATION WITH BILLINGSGATE.

THE proposal to remove the fish market from Billingsgate to some more easily accessible and convenient site has met, of course, with disapproval at the hands of many interested in its proximity to the river. The removal of a market is not effected without great cost, and there is always a risk of the new establishment proving a failure. Its improvement or removal being still under the consideration of the Corporation of London, Messrs. Vigers, of 2, Frederick's-place, Old Jewry, have submitted a plan for extending the existing railways into the port of London and to Billingsgate, thus, among other advantages, making the existing market easily approachable by land, without any loss of access by water. The promoters say the railways are all practically at Blackfriars, and to extend them along the foreshore of the river to Billingsgate, and thence to Tower Hill, will afford opportunity for the enlargement of the market and the acquisition of additional advantages. They propose to construct a new road from Adelaide-place, London Bridge, along the new line of embankment to Billingsgate, and thus afford relief to Lower Thames street, at presently fearfully overcrowded. If this were done both the Metropolitan Low Level Sewer and the Metropolitan District Railway might be carried through the new embankment to Tower Hill—the former according to Messrs. Vigers at a saving of £100,000 as compared with the expenditure required for the present inland course it is proposed to adopt. Application is to be made to Parliament during the next session, and plans, sections, &c., will be deposited during the present month.

TO CORRESPONDENTS.

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

MR. J. M. SMITH'S DRAWINGS.

To the Editor of the BUILDING NEWS.

SIR,—Of what have the subscribers to your esteemed journal been guilty that they should be subject to the pictorial eccentricities of J. Moyr Smith? At one time the animal, at another the vegetable kingdom, and sometimes both, are paraphrased and translated into new and anything but improved versions. And that a versatile mind may not be limited for a choice of subject, he leaves for a moment existing varieties and embodies the extinct "dodo," duly necklaced and clad in habiliments of the period, standing with astonished gasps at the audacity of modern art. In short, through the variety of Mr. Smith's inventions, your subscribers may be said (applying that gentleman's advice relative to one of his designs) to be "done in a variety of ways." Of these ways let me specify one or two; the cross, for instance, in illustration for August 28th, embellished with a series of animal heads most usually found both in number and perfection adorning the ends of umbrella sticks, but in this case leering at one another in a most congratulatory way at their good fortune in promotion from secular to sacred use.

Again, Mr. Smith's recent contribution, apologetically called "grotesques," the result evidently of Polynesian art studies, illustrating among other things seven different modes of eye-delineation, not, by the way, seven as symbolical of perfection in eye art, but as instances which "only touch on and by no means exhaust the number of treatments possible of the subject," and, it may be added, showing what ingenious arrangements of circles, dots, and notches are possible to an inventive mind. But, to speak seriously, the influence of these original and in some respects clever sketches on the unformed, impressible minds of young students of architecture is, in my opinion, not only unlikely to be in the least beneficial, but positively injurious. Mr Smith is an accomplished delineator of the human figure, but quite otherwise as a designer and composer of architectural forms; his outlines are crude and ungraceful, his details out of proportion, and his foliage conventionalised to mechanical mannerism.—I am, &c.,

G. S. A.

WATERPROOF WOODSHEDS.

SIR,—"W. S." Nottingham, in "Intercommunication" (1116), November 13, having given a description of "shingles" and their use in Norway and Sweden will you permit me to give a description of "shingles, &c.," in Canada? Shingles are either "split and shaved" or "sawn," and are manufactured of white pine, fir, cedar, spruce, &c. Shaved shingles are usually made in the bush, where suitable timber is to be found. There the "shingle weaver" sets up his "shanty" to protect him from the weather whilst carrying on his work. For shaved shingles straight-grained timber is sought and is usually found in fallen trees prostrated by the wind, which have lain several years and so are partially seasoned. The tree is cross-cut into lengths of 16in., and these blocks are split into a series of splints ¾in. thick, and varying in width as the diameter of the tree is reached. These splints are then placed and held in a "horse," upon which the weaver sits and shaves them with a "draw knife" down to their proper shape, which is as broad as the splint will make with parallel edges, the butt being ¾in. or 5-16in. thick, gradually tapering off to a sharp edge at the top. The longitudinal section of a shingle is a triangle 16in. in height and ¾in. or 5-16in. wide at the base. Sawn shingles are manufactured by a peculiar machine, which grasps the block of wood and presents it to the saw circular, which cuts the shingle off to its proper dimensions at once. A shingle is 4in. wide, and is put up for the market in bundles containing 250 and sometimes 500—that is, a bundle will not contain 250 separate pieces, but must contain so many pieces that their united widths when laid in work will equal 250 by 4in., or 83ft. 4in. One thousand shingles will cover a "square," allowing liberally for waste, which is generally large. Roofs are, as a rule, close boarded, and in starting work two thicknesses of shingles are laid at the eaves; at 4½in. or 5in. from the butts of this row a chalk line is snapped, and to it the butts of the next row (single this time) are laid with their edges abutting, and in like manner the work is continued to the ridge, which is always curved with a saddle board. The sides of buildings are sometimes shingled, and where sawn shingles are used they are sometimes planed and squared, and when carefully laid present a good appearance. A shingle is said "to be laid 4½in or 5in to the weather" when the distance apart of the butts of overlying rows is either 4½in. or 5in. Cut nails, somewhat larger than the lath nails in use here, are used, and are always so placed as to be covered by the next overlying row. Joints are broken as in slating. Shaved shingles are more durable than sawn, and command a higher price in the market.

A SHINGLE WEAVER.

DEAD MEAT MARKET.

SIR,—This important addition to the markets of London was opened on Tuesday by the Lord Mayor, and your reporter no doubt attended. We have observed the excellent notices of the building which have already appeared in your paper, but there has been no mention of the "Pyrimont Seyssel Asphalte," which forms the wide margins to all the shops and immediately beneath what are technically called the "butchers' hangings." So uniform and neat an appearance does this work in asphalte present that one cannot but remark that if the entire area had been floored with the same material it would have been, with a view to utility and cleanliness, a far better flooring than the wood pavement, the whole of which, with its countless joints, must absorb a great deal of offensive matter liable to become dangerously unpleasant during hot weather, and ultimately to necessitate the removal of the wood, whereas had asphalte been wholly adopted such a non-absorbent material could by a limited supply of water daily from the hydrants, have been made thoroughly wholesome.

Hoping your reporter's attention was directed to it when he visited the building on Tuesday,—I am, &c.,

J. FARRELL, Sec.

Seyssel Asphalte Co., 3, Parliament-street, S.W.
November 26.

GREEN SLATES.

SIR,—I was glad to see, in your article on Roof Coverings, attention drawn to the superior merits of green slates over any other colour. I cordially endorse all you say on the subject, and also what your correspondent, "Anti Tile," says as to the durability of some sorts. I think I know the

slate he refers to, and recognise a good hard Welsh slate under its classic title. There is no doubt if architects would only look into the matter a little more for themselves, they would find plenty of green slates, both cheap and beautiful, hard and durable. They are, however, too apt to select a green slate simply for its shade of colour, without reference to its texture or lasting qualities. I trust this question will be well ventilated, and that our fine public buildings will no longer be disfigured by the thin blue things that a mistaken economy places on them.—I am, &c.,

A QUARRY OWNER.

A CORRECTION.

SIR,—Having unintentionally attributed in a report I wrote on Class XVI. of the Paris Exhibition for our Government the credit of having executed a very satisfactory reproduction of a picture of Phideas by Mr. Poynter to Mr. Powell, of Whitefriars instead of to Messrs. Harland and Fisher, of Southampton street, Strand, I desire to make any reparation I can to them for this slip of my pen. I shall esteem it a personal favour if you will allow these few lines to appear in the next number of your journal.—I am, &c., M. DIGBY WYATT.

37, Tavistock-place, Russell-square, W.C.
November 21.

Intercommunication.

QUESTIONS.

[1137.]—POLISHING ALABASTER.—Will any reader kindly inform me as to the quickest, best, and cheapest way of polishing alabaster?—T. R. W.

[1138.]—THIEVES' VINEGAR.—What is thieves' vinegar? I have heard several speak of it as a good disinfectant, and should like to know of what it is composed?—CELEBATE.

[1139.]—LIME MEASURE.—I shall be obliged if some of your correspondents that are acquainted with the building trades will inform me how many bushels of lump lime are considered to be one cube yard; also the number of bushels of ground lime usually sold for a cube yard: and the cause of the difference, if any.—H. W.

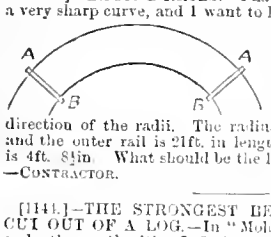
[1140.]—BUILDERS' CHARGES.—I should be much gratified could I gain some information as to what is right in the following: In cases where a large discount is allowed on materials (say 15 per cent. on plate glass, or 50 per cent. on gas piping), what ought a builder to charge, or who should gain the advantage of such discounts?—SURVEYOR.

1141.]—BACK NUMBERS.—I should feel obliged if any of your readers would kindly inform me, through the medium of "Intercommunication," where I can obtain the BUILDING NEWS for 1865, or whether they themselves have it to dispose of. I should prefer it in numbers, but if not, the volume will do.—A. Y. E.

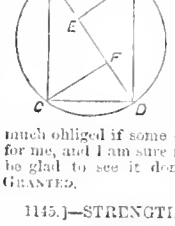
[Some of the numbers for 1865 are out of print; the remainder can be had from the publisher on application.—ED. B. N.]

[1142.]—VELOCIPEDE.—Will you or any of your numerous readers kindly inform me, through "Intercommunication," of the address of the builders of the velocipedes referred to in the BUILDING NEWS of Nov. 20, p. 799? and oblige—G. P. T.

1143.]—LAYING RAILS.—I have to lay some rails upon a very sharp curve, and I want to know how much I must cut off the inner rail, so as to make it of the proper length to bring the joints A and B (see figure) opposite one another, that is, in the direction of the radii. The radius of the curve is 200ft., and the outer rail is 21ft. in length. The width or gauge is 4ft. 8½in. What should be the length of the inner rail?—CONTRACTOR.



[1144.]—THE STRONGEST BEAM THAT CAN BE CUT OUT OF A LOG.—In "Molesworth's Pocket Book" and other authorities I find that the following rule is given to cut the strongest beam out of a log:—Divide the diameter A D into three equal parts, A E, E F, and F D, and from E and F draw the lines E B, F C at right angles to the diameter, then A B C D is the section of the strongest beam that can be cut of the circle shown in the figure. Now, assertion is no proof, and although I am unable to prove the thing myself, I should be much obliged if some of your correspondents would do it for me, and I am sure many of your readers besides would be glad to see it done.—ONE WHO TAKES NOTHING FOR GRANTED.



1145.]—STRENGTH OF JOINTS.—How should I calculate the strength of a pin, as shown in sketch, where a number of bars are joined together? This is the arrangement adopted in the chains of suspension bridges, but it does not seem clear to me how the proportions of the pins are arrived at.—DRAUGHTSMAN.

[1146.]—LOCAL BOARDS. Could any of your readers inform me whether there is any appeal against the decision of a Local Board, and if so, where to carry it? The Board of my district are carrying out some very stringent measures against some of the inhabitants, including myself, and we are thinking of taking action against them in the matter.—RATEPAYER.

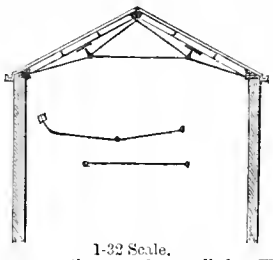
[1147.]—COPYING PLANS.—I have been recommended to get a pantagraph for reducing and copying a number of plans I have in hand, and I should be exceedingly obliged to any of the subscribers to "Intercommunication" if they would inform me what is the principle of the apparatus, and its probable price; also whether it is to be relied upon for producing accurate work. Some copying instruments I have seen are utterly useless so far as accuracy of reduction is concerned.—S. P. S.

[1148.]—CENTRE OF GRAVITY.—Can any reader inform me how to find the centre of gravity of a piece of iron (uniform) 16ft. long having 9ft. bent at right angles to 7ft.? and oblige—RAYMOND F.

[1149.]—FRICTION.—A ladder, 30ft. long, makes an angle of 30 deg. with the wall against which it stands. The coefficient of friction between the ladder and ground is .6, and between the ladder and wall .5. If the ladder weighs 4cwt. (84lb.) how high may a man weighing 11st ascend before it begins to slip? If any reader could solve the above I should feel obliged.—RAYMOND F.

[1150.]—CHARGE FOR STREET PAVING IN LONDON.—I shall be obliged if any of your circle of intercommunicants can inform me what is the usual charge made by the vestries of London parishes for paving the streets when they take possession thereof. I, an unfortunate provincial, have a house in London with a frontage of 16ft., causeway 9ft. wide, and half of carriage-way 15ft. wide. For paving the carriage way with Kent flints (including removing soil 15in. or 18in. deep) and taking up and relaying flags of causeway they demand £9 15s. per house. This seems to me an extortionate charge; and on public grounds, and as the reply to the question may be useful to some other readers, I venture to make this inquiry.—K. M.

[1151.]—ROOF CONSTRUCTION.—Will you or any of your correspondents be kind enough to give me your opinion of a roof of the kind I have sketched? There has been one of its kind put up in this town on a school, and it has come to grief, carrying the entire side of the building with it. Not being myself well up in such matters I should like some reliable authority on the subject. The roof was completed, slated, slate-pointed, and lathed and plastered to the small rafters, or spars as they are here called. What I want to know is, whether it is likely to have been the fault of the construction of the roof, and I should like to know the weight there is on the roof irrespective of lath and plaster—principal rafters 12in. by 4½in., purlins 8in. by 4in., common rafters 3in. by 2½in., roof tree 7in. by 3in., rods and pins 1in. round malleable iron, cast-iron shoes, struts and sockets for principal rafters and roof tree. The architect is a joiner.—R. SCHOOL.



1-32 Scale.

[1152.]—INDIAN INK.—Can any of your readers inform me where I can procure Indian ink that will not run when coloured over? I have tried various descriptions of ink on paper strained and unstrained, and have even laid the drawing aside for some weeks, but to no purpose, the lines always run more or less when colour was applied.—W. M. M.

[1153.]—DEALS AND BATTENS.—Will any of your correspondents kindly inform me the best manner of bringing a number of deals and battens of various sizes into St. Petersburg standard, or could they name any able and cheap work for that purpose. For example, what would the following expression mean:—731 pieces = 7 3-11 10-12? By kindly inserting the above you will confer a favour and receive the thanks of—ASPIRANT.

[1154.]—MAKING BRICKS WATERTIGHT.—Will some of your practical readers kindly give their opinion on the following points:—Is a coat of boiled oil on the outside of a house built with tolerably good bricks an effectual or partial preventative of rain driving through? I dislike the appearance of stucco, even if it were damp-proof, which I find is not always the case.—P. B.

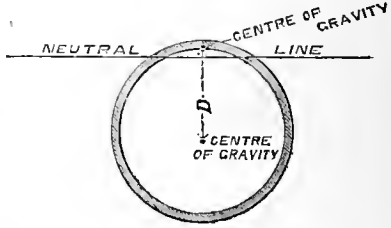
[1155.]—JOINTING STONEWARE.—What is the best material for jointing stoneware socket-pipes with when used for house drains?—P. B.

[1156.]—LEAD AND IRON PUMPS.—What kind of pump is best for raising water about 12ft. or so? Lead or iron are most recommended by their respective makers, but which or what is the most serviceable and easiest repaired, and best adapted for house use?—PROVEN BY PRACTICE.

REPLIES.

[1080.]—RETAINING WALLS.—I am very much obliged to "J. L." for his solution of the problem of finding the pressure of a surcharged embankment against a retaining wall. I think, however, there are one or two slight errors—misprints perhaps—in the letters and signs of it. The equation $G\ I = \frac{^2W\ x \times (b + x)}{W + {}^2W\ x}$ should be, I think, $G\ I = \frac{^2W\ x \times (b + x}{w + {}^2W\ x}$. The entire weight of wall also should be $w + {}^2W\ x$, and its moment $= \left(\frac{^2W\ x \times (b + x)}{w + 2\ W\ x} + a\right)$ $(w + {}^2W\ x)$, and the reduced equation will be, $x = \sqrt{\frac{o - w\ a}{^2W} + \left(\frac{a + b}{2}\right)^2} - \frac{a + b}{2}$. I shall be glad to know if these corrections are right. Also, should the thickness, as found, for exact equilibrium, be multiplied by 2 or 9-4, to give that required for stability? Or should the moment of the earth = o he first multiplied by 2 or 9-4, and the moment of the weight of the wall be made equal to it, and then the thickness of the wall found from that equation? There will be a difference between the thickness found by the first method and the second, and it was to this I referred in my question in No. 710, of Aug. 14, 1868. I mention this, as in the *Builder* of Dec. 28, 1867, in a paper on "Stability of Arches," the thickness found for equilibrium of the pier is not doubled, but the force to be resisted is doubled; and this equation gives a thickness for the pier much less than twice that required for equilibrium.—X + Y.

[1093.]—IRON PIPES.—The formula given by "Beta" for calculating the strength of a cast-iron pipe can only be an approximation when applied in the manner advanced; and I cannot see in what principle he thus applies it. Neither does the neutral line divide the pipe into two halves, but as shown on figure, dividing it into two portions, equivalent to the tensile and compressive powers which the material (cast-iron) has to resist these forces.



Their relative values are 6 and 1. Thus the area in tension = 6-7, and that in compression 1-7 of the whole area. The formula $\frac{A \times D \times C}{L}$ may then be applied, taking 6-7 the whole area = A, and D = the distance between the centres of gravity (which are the centres of pressure) of the two areas. For a wrought-iron pipe the same formula will apply, with a different value for C, and the area divided in the proportion of 16 to 20, or $A = \frac{\text{area} \times 16}{20.}$ c = 80. The approximation of "Beta's" formula is close, inasmuch as the upper area bears so small a proportion to the lower, and would be correct were the whole area in tension, or, rather, neutral at the top and exerting a maximum force at the bottom.—W. P.

[1096.]—STIFFNESS OF BEAMS.—I wish to point out the serious error made last week by "Architect" in the formula for the depth. He gave it thus:

$$D = \frac{\sqrt[3]{L^2 \times W \times C}}{B}$$

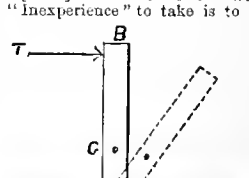
It should have been thus—

$$D = \sqrt[3]{\left(\frac{L^2 \times W \times C}{B}\right)}$$

PURLIN.

[1110.]—ANCIENT LIGHTS.—"H. C." may proceed to build his house as high as he likes provided he leaves the proper distance between the two walls. No one can claim the exclusive right of putting in a window that shall overlook uninterruptedly another person's property.—F. H.

[1112.]—STRENGTH OF WALLS.—The first step for "Inexperience" to take is to ascertain the value of the outward thrust, and he may then proceed as follows: It is a simple case of leverage. Let T = the outward thrust; R the resistance of the wall, which will of course act at G, the centre of gravity of the wall; and H its height. The forces tending to overthrow the wall by turning it about the point A are the thrust multiplied by the height of the wall; and those tending to maintain it are R multiplied by the distance of the centre of gravity from the point A, multiplied by the weight, W, of one cubic foot of the wall. Thus we have $T \times H = R \times A\ G$, and $R = \frac{T \times H}{A\ G \times W.}$



As a rule, the mean thickness of the wall may be taken equal to $\frac{H}{6}$, and the wall must be battered at the rate of one inch to the foot. I would strongly recommend "Inexperience" to put in a tie beam, and not run the chance of overturning the wall. Walls are very rarely built now to take thrusts, except those of arches.—HEYTON.

[1117.]—DISCOLORATION OF STONE.—There is only one way of removing the discoloration your correspondent mentions, and that is to have the stone re-tooled. No washings or solutions of any kind will be of the least use.—MASON.

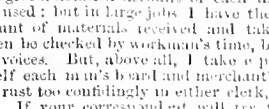
[1121.]—BATTER OF WALLS.—There is not the slightest necessity for continuing the batter of walls below the ground level. You may run them down plumb, as in the sketch given in the BUILDING NEWS of the 13th inst. The best way to get your curve is to plot off the top and bottom thicknesses of the wall, join them by a straight line, and then strike a curve that touches the inside of the line at top and the outside at bottom.—SURVEY.

[1128.]—CALCULATION OF PRIME COST.—In answer to your correspondent, I trust he will not be offended in the opinion I am about to express—viz., that he must have a very imperfect way of keeping his accounts if he cannot find, at the close of a contract, what profit he receives from the same. I am afraid both contractor and contracts will come to grief before long if he does not alter his ways. I beg to inform him of my way of doing business—viz., to have a separate heading for each contract

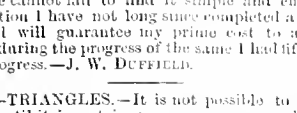
with debtor and creditor columns, entering in debtor column every week each item received from own yard, merchants, &c., including all wages, of course, all at prime cost, so on until close of contract, then cast up and take total. In the creditor column I enter all materials which have been taken away from one job to another at prime cost price, then at close of job the total credits are deducted from the debtor column, and the balance consequently is the prime cost. Of course the workmen who take the materials from a contract job give a detailed account of each day's work and material used; but in large jobs I have the foreman keep an account of materials received and taken away, which can then be checked by workman's time, board, and merchants' invoices. But, above all, I take especial care to check myself each man's board and merchant's invoice, and not to trust too confidingly in either clerk, foreman, or workmen. If your correspondent will try the above method he cannot fail to find it simple and effective. I may mention I have not long since completed a £600 contract, and will guarantee my prime cost to a shilling, although during the progress of the same I had fifty smaller jobs in progress.—J. W. DUFFIELD.

[1129.]—TRIANGLES.—It is not possible to solve this problem until it is put in a proper manner. How can a line be measured by degrees? What result does "R. F." expect? A boast is made of being somewhat of a mathematician, and yet two lines meeting at a point are called a triangle.—H. F. P.

[1129.]—"R. F.'s" problem may be solved, with the aid of a right angled triangle, in the following manner: Given A B = 30; ∠ B A C = 40°; and difference of sides A C and B C = 10°.



Let fall a perpendicular from B on A C, cutting A C in D



Then—As log. sin. B D A, 90° = 10
: log. A B 30 = 1.47712
:: log. sin. A B D, 50° = 9.88425
: log. A D, 23° = 1.36137

Let D C = x. Then A C = (A D + x) = 23 + x; and B C = (23 + x) — 10 = 13 + x. Then—As the whole base (23 + x): sum of the other two sides, 30 + (13 + x) :: difference of those sides, 30 — (13 + x): difference of segments of base (23 — x)

$$\therefore (23 + x)(23 - x) = \left\{30 + (13 + x)\right\} \times \left\{30 - (13 + x)\right\}$$

a simple equation, from which x = 7 10 13.
∴ A C = 23 + x = 23 + 7 10-13 = 30 10-13; and B C = 13 + x = 13 + 7 10 13 = 20 10-13.—J. G. SINGLE.

[1134.]—LATEST PRICES OF MATERIALS USED IN CONSTRUCTION.—Charles Cane and Co., of Baltic Wharf, Wisbeach, write to say that they should be glad to supply "Young Beginner" with price list of deals, &c.

[1135.]—QUESTION IN STATICS.—
[C. D.'s answer to this question contains some algebraic signs which we have not got, and cannot procure. Some of C. D.'s signs are written so indistinctly that we cannot make them out.—ED. B. N.]

WATER SUPPLY AND SANITARY MATTERS.

THE Queen has been pleased to appoint the Right Hon. Thomas George, Lord Northbrook; the Right Hon. Charles, Earl of Romney; Francis Wemyss Charteris, Esq. (commonly called Lord Elcho); the Right Hon. Charles Bowyer Adderley; the Right Hon. Henry Austin Bruce; Sir Thomas Watson, Bart., M.D.; Sir Charles Lanyon, Knt.; Lieutenant-Colonel Charles Brisbane Ewart, R.E.; John Robinson M'Clean, Esq., C.E.; George Clive, Esq.; Francis Sharp Powell, Esq.; Acton Smee Ayrton, Esq.; Roger Sinclair Aytoun, Esq.; Benjamin Shaw, Esq.; John Lambert, Esq.; James Paget, Esq., F.R.C.S.; Henry Wyldbore Rumsey, Esq., M.D.; Henry Wentworth Acland, Esq., M.D.; Robert Christison, Esq., M.D.; William Stokes, Esq., M.D.; and Samuel Haughton, clerk, M.D.; to be her Majesty's commissioners to inquire into and report on the operation of the sanitary laws for towns, villages, and rural districts in Great Britain and Ireland, so far as these laws apply to sewerage, drainage, water supply, removal of refuse, prevention of overcrowding and other conditions conducive to the public health. Also to inquire into and report upon the operation of the laws for preventing the introduction and spreading of contagious and infectious diseases, and of epidemics injurious to the public health. Also to inquire into and report upon the local administration of the aforesaid sanitary laws, namely, the constitution and action of the respective governing or managing bodies and the formation of the districts in which these laws are carried into execution. Also to inquire into and report upon the operation of that part of the registration system which relates to certificates of causes of death, with power to suggest improvements in all or any of the matters aforesaid, and in particular to distinguish any laws that should be obligatory in their operation from those which should be permissive only, and any laws which should be generally applied from those which should be confined to populous places or particular localities.—*Gazette.*

STATUES, MEMORIALS, ETC.

AN equestrian statue of the present Emperor of the French has just been fixed over the new gateways that lead beneath the great gallery of the Louvre into the Place du Carrousel. The work is a close imitation of the well-known equestrian statue of Henry IV. over the central entrance of the Hotel de Ville. It is executed in half relief, in bronze, and is of great size, measuring about 14ft. each way, and weighing nearly a ton. It is being fixed to the stonework by means of 16 or more bronze bolts, screwed into sockets in the marble. The Emperor, in the costume of the Cæsars, is crowned with laurels, and holds in his left hand and resting upon his thigh the imperial sceptre. The work is said to be by the able sculptor Parye.

STAINED GLASS.

A STAINED glass memorial window has been placed recently in the north aisle of St. George's Church, Ramsgate. The window was prepared by Messrs. Warrington, of Hyde Park, and is executed in the architectural style of the fifteenth century. The general character of the drawing and canopy is appropriate. The latter consists of the passion-flower, the blossoms being richly blended with leaves. The subject is taken from the 1st chapter of the 1st book of Samuel, and illustrates the death of Jonathan.

LEGAL INTELLIGENCE.

RE LUNDY GRANITE COMPANY.—On the 19th inst., in the Chancery Court, Lord Romilly gave judgment in this case, in which two petitions—one by the National Bank of Ireland and the other by shareholders—had been presented, praying for an order to wind up the Lundy Granite Company. It was not disputed that an order to that effect must be made, but the second petition contested the claim (over £15,000) of the National Bank, and made grave charges against the National Bank, in relation to the Lundy Granite Company. It was not necessary, nor indeed desirable, to enter now into these charges in detail. It was sufficient for the court to say that the charges against the directors of the National Bank, or, at least, four of them, were that they had carried on a species of trade in launching and winding up joint stock companies for their own benefit; that, in fact, the National Bank was the Lundy Granite Company, that the claim of the National Bank was illusory, and such as the shareholders of the Lundy Granite Company were not legally liable to pay. The charges, which were supported by affidavits, were not satisfactorily answered. Indeed, the directors avowed that they declined to answer the charges fully, on the ground that this was not the time for entering into them, and that that should be done in the course of the winding up. He could not dismiss the petition of the National Bank without saying that their claim was invalid, but at present he could not determine that question. He could not dismiss the second petition without coming to the conclusion that the charges contained in it were frivolous and unsubstantial; but, after having read the whole of the evidence, he was of opinion that there was matter of grave importance to be tried, and that the conduct of the directors of the National Bank could not be properly disposed of under a winding up order obtained and carried on by them selves. He thought the best course was to make one winding-up order on both petitions; but that the carriage of it should be given to the second petitioners.

JENNING *v.* BULL.—A case of some importance in connection with the Metropolitan Buildings' Act came before Mr. D'Eyncourt last week on a summons taken out by Mr. Joseph Jennings, district surveyor for the south part of St. Marylebone, against Mr. Edwin Bull, an architect, of 16, Holles street, Cavendish-square, and owner of a house No. 9, Duke street, Portland-place. It appears the house in question has been rebuilt, and a claim for district surveyor's fees made in due course, his fee being for inspecting arches under public ways, 10s., which Mr. Bull objected to on the ground that the arches had not been touched. On this objection being made Mr. Jennings withdrew his claim, but substituted another of 7s 6d, for "alteration made to building after the roof had been covered in, situate in front of No. 9, Duke street." Such "building," Mr. Jenning explained, was the coal cellar, and the alteration was the taking down a portion of the area wall on which the area railings stand, and an alteration entitled him to half the fee charged on a new building under 100 superficial feet and one story high, viz., 7s 6d. Mr. Bull denied his liability, contending that what had been done was by way of necessary repair, and moreover that vaults and cellars under public ways could not be deemed buildings; if so why did not the Act style them so? whereas it continually referred to them as arches and floors under public ways, and there was a distinct fee payable to the district surveyor on these arches and floors under public ways being disturbed. The other two vaults might also be considered buildings, and why had not Mr. Jenning charged a fee on each of them? In support of these views Mr. Bull called Mr. Henry Baker, district surveyor for St. Pancras, and surveyor to the Duke of Portland, and he stated that he had inspected the premises, 9, Duke street, and found that what had been done was only by way of necessary repair, and that a cellar or vault under a public way was certainly not in his opinion a building under the Act, that the area wall in question did not come under the regulations of the Act as regards the material it was to be built of, nor was it liable to the fee Mr. Jenning had charged, and that during his experience of more than thirty years as district surveyor he had never made such a charge or seen such a charge made. Mr. D'Eyncourt deferred his decision for a week, and now said that a cellar was in his opinion a building, and that the taking down a portion of the area wall he considered was the external wall of such building, and as such was liable to the fee Mr. Jenning had charged; but he, Mr. D'Eyncourt, thought it rather a harsh proceeding, inasmuch as he had ascertained that it was not the practice of district surveyors to make such a charge; therefore he asked Mr. Jenning whether he would press for an order. Mr. Jenning said he merely wished the magistrate to decide under the Act. Mr. D'Eyncourt said he would allow the order to stand over for three days, as he would certainly grant a case for a superior court if Mr. Bull desired. Mr. Bull attended at the expiration of the three days to point out to the magistrate that there was no appeal, a fact that the magistrate's attention had been called to by a note from Mr. Jenning. Mr. D'Eyncourt said he should have been glad if there had been an appeal, as the Act was difficult of construction, and required arguing on both sides. Mr. Bull said he should not have appealed, as it would have taken up far too much of his time, but he regretted not being better prepared to argue the case when the hearing came on, but he Mr. Bull was at a loss to understand the point Mr. Jenning intended to raise, as it was admitted by him that a cellar under a public way was a building. Perhaps at a future time a [illegible] the legal Professor in Mr. D'Eyncourt, by counsel, with proper models of the premises, for without the latter it was difficult for non-members of the profession to understand cases of this kind.

Our Office Table.

SOME colossal schemes are in hand by the French government and financiers for improving Trouville, the new watering-place on the Norman coast, near Havre, which has lately become a place of English resort. There are already some fine buildings there, erected by a French architect, who distinguished himself in the London competition for the Palace of Government.

The earliest architectural periodical in England appears to have been the *Builder's Magazine, or Monthly Companion for Architects, Carpenters, Masons, Bricklayers, &c.* London: 1774. It was in quarto, and the whole series contained 185 plates. In five or six years we shall complete the centenary of the architectural press.

The death is announced at a premature age of Harmer E. Moore. He was for some time engineer of the Smyrna and Calabar railway. It is supposed illness was brought on by over-exertion in preparing the drawings for a townhall competition, in which he carried off a premium of fifty guineas. He was a very fair amateur artist.

A correspondent says:—"In its essence, then, Ritualism as now cultivated, both in its milder and its more audacious forms, is an æsthetic movement. It is a protest against the miserable meagreness and ugliness of the old-fashioned puritanical rigorism. Its connection with the Roman eucharistic dogmas, and Roman Mariolatry and saint worship in general, is little more than accidental. Undoubtedly, the æsthetic system of public worship finds in sacramentalism, and especially in the doctrine of the real presence, a splendid opportunity for its development. But that is all. The spirit of Ritualism—that is, a love for something more than a bare decorum in public services—is everywhere at work. It has covered the country with restorations of churches, cathedrals, and chapels, and with new churches and chapels almost innumerable. High Church, Low Church, Middle Church, Wesleyan, Independent, Baptist, Unitarian, ultra-Protestant, and ultra-Roman alike—every branch of the Christian Church has caught the soft infection.

A writer in the *Daily News* says:—"To those who have advocated the concentration of the Law Courts, it is unsatisfactory to find that when their labours seemed destined to bear fruit, when Parliament has given its assent, when the site has been purchased, and nothing left but the choice of the design, the prospect of this generation profiting by these labours grows daily more faint. A few persons of sanguine temperament thought that when the battle of the architects was ended the work would go on vigorously. Well, the architect was nominated several months ago, and not a step in advance has yet been made. The site is not even cleared for the reception of the foundation. There appears no likelihood of the uninhabited tenements which partially cover it being pulled down for years to come. One or two men are employed at intervals to demolish these houses and cart away the materials, and they will doubtless succeed in finishing their task in the course of ten or fifteen years. When we remember that private enterprise can design and erect a Crystal Palace in one year, we may fairly ask the Government to arrange for the erection of the Hall of Justice in the course of at least ten years.

The National Gallery has received the large family picture by Gainsborough, which was bequeathed by the late Mr. Alexander Baillie, and which, according to the testator's intention, remained in the hands of the late Mr. M. J. Higgins until his death.

A fire broke out on Monday morning, about seven o'clock, on the premises occupied principally by Messrs. Grieve and Co., the well-known scene painters, situate in Charles street, Drury-lane. The building was at least 100ft. deep, about 50ft. wide, and three floors high. A large number of elaborate scenes for the Christmas pantomimes were being prepared, all of which have been destroyed.

The following candidates have been admitted students of the institution of Civil Engineers: Charles Toler Burke, George Ernest Faithfull. Henry James Samson, and Herbert de Symons Skipper.

The monument to Ingres, the distinguished French artist, has been recently completed at Père-la-Chaise. It consists of a Greek cippus, designed by M. Baltard, architect, and a bust of the artist by M. Bonassieu.

The inhabitants of Holloway and Islington are much disappointed at the decision of the Metropolitan Board respecting Finsbury Park. They were originally promised 250 acres, then it was cut down to 131, now it only consists of 118 acres, yet the Metropolitan Board still intend to sell twenty acres—the number originally fixed upon when the area was to consist of 250 acres—for building purposes. The St. Pancras Vestry and the Holborn Board of Works favour the Metropolitan Board's proceedings from motives of economy. There seems to be now no means open to the disappointed inhabitants except an appeal to Parliament.

The usual fortnightly meeting of the Edinburgh Architectural Association was held yesterday week in the hall, 5, St. Andrew-square—Mr Alexander Ballantine, president, in the chair. Mr. W. G. Shiells read a paper entitled "Notes on Architectural Detail." He commenced by referring to the several merits of Grecian and Gothic architecture, and continued by drawing attention to the prominent features in architectural detail, pointing out what he considered worthy of study and what should be avoided. After remarks from several of the members, a vote of thanks was proposed by Mr. J. Ross to Mr. Shiells and cordially agreed to.

M. Legros, a French artist, who has resided in London for several years, and who has made himself a certain reputation for his pictures of incidents of monastic life (his lectern exhibited two years ago, and the refectory in last year's Royal Academy Exhibition, will be remembered), has presented the Museum of Dijon with a picture which formed part of the Paris salon of 1861. It represents a calvary in the Campagna, in front of which a group of women are kneeling in prayer. This group is all that remains of a picture that many of the artist's friends will recollect to have seen in his studio at the commencement of his career, then called "The Removal of the Bier." This picture has been entirely repainted. M. Legros is engaged upon a picture of St. Sebastian, of which report speaks well.

The Hôtel Carnavalet, Paris, formerly the residence of Madame de Sevigné, is being converted into a museum for the antiquities of Paris. An interesting operation is now being carried out, namely, the transplanting, stone by stone, a curious arch, constructed in the time of Henry II., and which formed part of the dependencies of the Prefecture of Police. This arch originally crossed the old Rue de Nazareth; it formed a communication between two public offices, the Cour des Comptes and the gallery of the Archives.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Royal Institute of British Architects.—"On Mosaic Decoration," by A. H. Layard, M.P., D.C.L.

TUESDAY.—Institution of Civil Engineers—"Description of the River Witham, and of its Estuary and of the Works upon it," by M. A. H. Wheeler, M Inst. C E., &.
Anthropological Society, 8.

WEDNESDAY.—Society of Arts.—"Further notes on the Productive Industries of Natal," by Dr. Mann, Superintendent of Education and special Commissioner for the Colony, 8.

THURSDAY.—Linnean Society, 8.

Trade News.

TENDERS.

CATERHAM.—For the erection of a dwelling house and shop on the Godstone road, Caterham, Surrey. Mr. Geo. Robson, architect:—

Ball	£679 10
Galyer	676 0
Francis (accepted)	650 0
Elliff	643 0

CHISLEHURST.—For the erection of a villa residence with boundary walls, &c., complete, at Chislehurst, Kent, for D. Chattell, Esq. Joseph S. Moye, architect:—

Grover (accepted)	£4016

LONDON.—For rebuilding No. 22, Villiers-street, Strand, for Messrs. Stevens and Sons. Mr. W. H. Saunders, architect. Quantities supplied by Messrs Rake and Ranwell:—

Carter and Son	£1367
Baguley	1211
Downs	1127
Macey	10 8
Clemence	1090
Read	854

RAMSGATE.—For the erection of a villa on lots 5, 6, and 7, of the Ellington estate, for Mr. Cooper. Mr. John R. Collett, architect:—

Wade	£1005 10 0
Forewalk	995 19 11
Osborne	988 0 0
Duckett	978 0 0
Elgar	915 0 0
Kelson (accepted)	875 10 0

SOUTHALL.—For the erection of cisterns and water pipes at St. Marylebone Schools, Southall. Mr. H. Saxon Snell, architect:—

Dennis and Scruby	£495 0
Benham and Sons	450 0
Jennings	418 0
Jeakes and Co.	398 7
Potter and Sons	375 0

COMPETITIONS.

INDIA.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

PRIORY ESTATE, DOVER.—December 15.—For laying out about 13 acres of building land. Premiums of 50 and 25 guineas. Mr. S. Finnis, Biggin-street, Dover.

SOUTH METROPOLITAN SCHOOLS, SUTTON (Surrey).—February 2.—For designs for the erection of an infant establishment adjoining the present schools. Premiums of 40 guineas each for the three designs considered the best. J. Burgess, clerk to the managers, Vestry Hall, Walworth.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

LEICESTER WATERWORKS.—December 8.—For the construction of a large storage reservoir, &c., and for the erection of an engine and boiler house, and other works. J. H. Williams, secretary, Waterworks offices, Bowling Green-street, Leicester.

HAMPTON COURT AND WALTON BRIDGES.—December 16. Tender for tolls. Mitre, Hampton Court.

ST. JAMES'S CHURCH, GREAT YARMOUTH.—December 12.—For the erection of a portion of this church. J. P. Seddon, architect, 12, Park street, Westminster.

REIGATE.—For completing a residence at Reigate. J. F. Matthews, London road, Reigate.

ST. MARY ABBOTT, KENSINGTON.—For the construction of about 1,100ft. of brick sewer. Mr. J. Whitchurch, surveyor, 7, Lincoln's Inn Fields.

STREATHAM.—December 1.—For the construction of about 3,480ft. of brick sewers. A. A. Corsellis, Battersea rise, Wandsworth, S W

LINCOLNSHIRE.—December 5.—For the restoration of Gunby Church, near Burgh Station. J. Fowler, architect, Louth.

BRISTOL AND EXETER RAILWAY.—December 3.—For purchase of old stores, brass, &c. A. Moore, secretary, Railway offices, Bristol.

LEICESTER WATERWORKS.—December 8.—For the execution of the works comprised in Nos. 4 and 5 contracts. J. H. Williams, secretary.

BARFORD.—For the erection of hospitals and other buildings in connection with the union. R. B. Spencer, clerk to the Guardians.

PROPERTY SALES.

NOVEMBER 16.

AT THE MART.—By Mr. Whittingham.—Freehold building land, situate in Rendle-ham road, Clapham, in 45 lots—Lot 1 sold for £370; lots 2 to 4, £125 each; lots 5 and 6, £140 each; lot 7, £475; lots 8 to 13, £120 each; lots 14 to 21, £105 each; lots 22 to 25, £ 00 each; lot 26, £450; lots 27 to 29, £215 each; lots 30 and 31, £85 each; lots 32 to 34, £90 each; lots 35 to 38, £85 each; lots 39 to 45, £80 each.

Freehold two cottages, situate in Western lane, Nightingale lane, Clapham—£425

Freehold two cottages, situate in Western lane, Nightingale lane, Clapham—£425.

Freehold two cottages, situate in Western lane, Nightingale lane, Clapham—£455.

NOVEMBER 17.

At Garraway's.—By Messrs. Warlters and Lovejoy.—Leasehold premises, No. 23, Paternoster row, producing £562 per annum, term 59 years from 1867, at £160 per annum—£5,040.

NOVEMBER 18.

At the Mart.—By Mr. A. Savill.—Leasehold house and shop, No. 37, Great Tower street, and three tenements Nos. 24 to 26, Beer lane, producing £117 14s. per annum, term 19 years unexpired, at £46 per annum—£1,050.

NOVEMBER 19.

At the Mart.—By Mr. Geo. Newman.—Leasehold profit rental of £102 per annum (for 18 years) secured on Nos. 20, 22, and 24, Essex road, Islington—£610.

NOVEMBER 20.

At the Mart.—By Messrs. Rushworth, Abbott, and Company.—Freehold 7a. 1r. 5p. of building land, with residence thereon, known as Royston Hall, Kilburn—£7,400.

By Messrs. Norton, Trist, Watney, and Company.—Leasehold residence known as Springfield House, Lower Tulse hill, let on lease at £130 per annum, term 72 years unexpired, at £31 6s. per annum—£1,700.

NOVEMBER 23.

At the Mart.—By Mr. Whittingham.—Freehold building land, situate at Stamford hill, in 29 lots, lots 1 to 35 comprised previous sales:—Lots 36 to 38 sold for £150 each; lots 39 to 41, £145 each; lots 42 to 44, £130 each; lot 45, £175; lot 46, £310; lot 47, £100; lots 48 to 50, £ 0 each; lot 51, £80; lots 52 and 53, £85 each; lot 54; £100; lot 55, £85; lot 58, £100; lot 59, £95; lot 60, £100, lot 61, £90; lot 62, £90; lot 63, £180; lot 64, £140; lot 65 £90.

By Messrs. Bromley, Son, and Kelday.—Leasehold improved rental of £30 per annum on Nos. 1 and 2, St. George's mews, Regent's Park road, term 79 years from 1853—£310.

Leasehold residence, No. 13, Theberton street, Upper street, Islington, producing £61 per annum, term 82 years from 1832, at £6 16s. per annum—£670.

Leasehold house, No. 35, Northampton street, Clerkenwell, let at £34 per annum, term 73 years from 1805, at £1 per annum—£155.

Leasehold three houses, Nos. 7 to 9, New Charles street, City road, producing £63 10s. per annum, term 99 years from 1843, at £16 10s. per annum—£5 5.

NOVEMBER 24.

At the Mart. By Messrs. Debenham, Tewson, and Farmer.—Reversionary interest of a gentleman, aged 28, to one third of a freehold estate, known as the "Ferns," in the parish of Lydd, Kent, comprising 35 acres of marsh land, with cottage and buildings, subject to an annuity of £90 during the life of a lady, age 65 years—£200.

By Messrs. Toplis and Harding.—Leasehold residence, No. 30, Mornington road, Regent's Park, term 66½ years, at £22 per annum—£470.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

Ambrey Hercules Angell, Chalvey, near Slough, builder, December 2—Edward Charles Birt, East India road, contractor, December 2, at 12—Charles Jabez Cash, Whitehorse street, Stepney, zincworker, December 3—Benjamin Chandler, Worth, Sussex, builder, December 2, at 1—John Smith, Appleford road, Westbourne Park, stonemason—James Edward Ward, Plaistow, builder, December 3, at 11—Edward Foley, Leyton, Essex, builder, December 9, at 1—William Mackenzie, Colchester street, Pimlico, builder, December 9, at 12—William Sparrow, Acton, carpenter, December 10, at 11—Joseph Spurrell, South Norwood, locksmith, December 9, at 2—William Townsend, St. Mary Cray, builder, December 7, at 11—Joseph Wheeler, Althorpe road, Wandsworth Common, builder, December 9, at 12.

TO SURRENDER IN THE COUNTRY.

John Buckley, Davenham, Cheshire, builder, December 3, at 11—Richard James Lawes, Caister, carpenter, December 1, at 12—Matthew Duckworth, Bowling, Yorkshire, stonemason, December 4, at 9.15—Robert Joseph Jones, Liverpool, builder, December 4, at 11—Nicholas Thomas, Merthyr Tydfil, contractor, December 8, at 11.30—Frederick Woor, Loddon, brickmaker, December 9, at 10.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

December 11, R. Gooch, Hertford road, Kingsland, plumber and glazier—December 11, J. H. Lance, Croydon, builder—December 11, J. M. Smith, Cornhill, architect—December 14, W. H. Kimmins, East End, Finchley, brick merchant—December 14, V. Cooper, Lewisham, builder—December 8, J. Finning, Pinhoe, Devonshire, builder—December 5, J. H. Bates, Wolverhampton, brick dealer—December 16, A. Barrett, Donhead St Andrew, stonemason—December 3, B. Scotting, Wilton road, Shepherd's Bush, builder—January 8, J. W. Somerville, Meyrick road, Clapham Junction, plumber—January 11, J. P Crowther, Marlborough square, Chelsea, stonemason—January 12, W. Crimp, Dale road, Kentish Town, carpenter—December 9, E. Flanagan, Ashtead, builder—December 9, E Frost, Forest hill, builder—December 22, W. Clamp, Leicester, builder—December 11, E. C. M. Walker and D. A. Jones, Liverpool, timber merchants—December 4, W. F. Ireland, Bolton, slater—December 15, T. Holmes, Tranmere, Cheshire, architect—December 7, A. Kane, Carlisle, joiner.

PARTNERSHIPS DISSOLVED.

Dowbiggin and Legge, Leeds, builders—Palmer and Co, Old street, varnish manufacturers—Younger and Co., Leeds, timber merchants.

DIVIDENDS.

December 9, H. Shepherd, Old street road, timber merchant—December 17, S. J. and J. Dudbridge, Stroud, builders.

SCOTCH SEQUESTRATION.

Andrew David Crow and James Horatio Thomson, Lochgilphead, builders, November 25, at 12.

THE BUILDING NEWS.

LONDON, FRIDAY, DECEMBER 4, 1868.

FAIRFORD WINDOWS AND THE ROYAL ARCHÆOLOGICAL INSTITUTE.

THE beautiful stained glass windows at Fairford have so long, notwithstanding the out-of-the-way place where they are, excited the interest of all who care for such things, that no assertion of Mr. Holt is more unfounded than that they have been neglected by artists and the public in general. It is true that the claims of Albert Durer to the authorship of them had not been publicly and seriously advocated before Mr. Holt produced his marvellous and audacious list of assertions unsupported by one jot of evidence, grounded upon a judgment which was formed without even the trouble being taken of seeing the things commented upon. Never was a controversy carried on with such an exhibition of contempt for all the judgment of predecessors and contemporaries, and with so little to justify the assumption of such an unusual tone of self-assertion. Mr. Holt, as a writer in *Notes and Queries* has remarked, is unable to take up his pen without being obliged to laugh or smile, or give ironical thanks for supposed but mis-directed kindness. Mr. Holt has made up his own mind apparently without any data to go upon, except trifling fancied scraps of circumstantial evidence, and then he seems furious with the world because they want something more. We are not going to question for a moment the importance of the series of glass pictures at Fairford. We have always considered them among the most charming specimens both for colour and design that we have seen. All we object to is the attribution of them to Albert Durer, whose style none of them in the least resemble; and even if they did it would take a great deal more evidence than has yet been produced to prove that they were executed by that giant of an artist. The attempt to prove his concern in this matter upon such data as Mr. Holt brings forward is almost ridiculous. If he could point out the hand of the master, by comparison with acknowledged works, and, better still, if he could produce some collateral evidence of Albert Durer's connection with glass painting, he would have commanded respect and have merited the thanks of all who take interest in his biography. But that he considers far from necessary. When "J. C. J.," in the *Standard*, insisted upon some direct affirmative documentary evidence of Durer's having to do with glass painting, and especially that at Fairford, he was met by an attempt to turn his letter into ridicule. Mr. Holt presumed that the writer expected him to find and produce the original invoice to the goods:

"James Thane, Esq.,
Dr. to Albrecht Durer, of Nuremberg.
To 28 windows painted for your ch., &c."

Does Mr. Holt know that, as a matter of fact, very few names of architects, painters, or sculptors of the middle ages, and some as late as the fifteenth century, in Western Europe at least, can be identified except by evidence very nearly approaching to that which appears so impossible and absurd to him—very nearly all we know of mediæval architects, &c., is from the entries in the church accounts or chronicles? Neither Englishmen, Frenchmen, nor Germans were in the habit of parading their names. They did their lovely work for the love of it, so that in the finest illuminated books, for instance, we hardly ever see a name, date, or place. One cannot help admiring so unselfish and noble a trait in the character of these people, though historically it is a great pity that we have lost such interesting information. It would not have been an easy matter to prove the English origin of the charming Devoniensis Bible in the British Museum if the writer had not fortunately and contrary to custom inscribed the volume with his name. But, on the other hand, we have nothing but the skilled eye to guide us to pronounce upon the English origin of the glorious Tennyson Psalter and Queen Mary's Book 2 B. 7. For this reason Mr. Holt's argument, that we are bound to find a name for the author of these windows if we reject that of Albert Durer, is groundless. There are comparatively few windows or sculptures, or buildings either, before 1500 to which you can assign the names of the artists or architects. By the way, we may as well here express our surprise at Mr. Holt's difficulty about the first printed books wanting names, dates, and places, and his assertion that there must be some particular intention in the omission. Why, we should like to know, should it be expected that the first printed books should have these when we know that of the MSS., in strict imitation of which—(so strict, in fact, that at the first glance the unpractised eye would mistake the one for the other)—these printed books were made, not one in a thousand had anything of the kind? We will not enter into the question of the block books because no one with any knowledge of art can for a moment believe that they were all or any of them the work of Albert Durer, bearing as they do upon the face of them various dates, hands, and countries, and, secondly, because we know it is quite useless to try to persuade Mr. Holt. When Mr. Noel Humphreys alleged the existence of a block book in a binding of 1420 or '30, we were told at once that either the date or the binding was wrong, or that the book had been, for some fraudulent purpose, inserted in the old cover of some MS. So again when at the late meeting of the Royal Archæological Institute, he was told that there was a date perfectly plain, though partly obliterated—Anno Domini 1467—"he did not believe in Anno Domini at all, at anything like the date. The date had been put on." In neither of these cases did he make the assertion *because he knew it to be true.* They interfered with his theory, and so they couldn't be true. *He had never seen either, he allowed;* but what of that? His theory was right, and if facts were against it, so much the worse for the facts. But the most amusing case of all was the celebrated St. Christopher, at Althorp, with the date 1523. The particular copy, by the bye, in the Spencer collection, has always been allowed to have been *printed* with printing ink, by a printing press, though the block is supposed to be of the date inscribed. Well, this is the way Mr. Holt has treated this part of his subject. One would have thought that a gentleman about to contest, in the most positive and not over-courteous manner, the opinion of the general public would have taken the trouble to examine so well known a print as this; especially when the courtesy of Mr. Cavendish Boyle is so well known. But no such thing; without even having seen the original he pens this sentence: "I am an utter unbeliever in dates of literary and artistic curiosities prior to 1500. As the most perfect justification of my disbelief in early dates, I denounce the date upon Lord Spencer's St. Christopher of 1423, so implicitly believed to this moment to be the earliest known woodcut with a date, to be a forgery, and that the true date is 1493. I further say that this forgery was effected by altering the C of the X C into an X, by which simple process seventy years was forthwith added to the date; and I also declare that the St. Christopher in question was executed by Albrecht Durer, at Colmar, in 1493, on the occasion of his visit to the brother of Martin Schon." Now here we see he attributes this cut to Albert Durer, not because it is in the least like anything that he is known to have done—it is no more like his work than it is like Bewick's—but simply because of the date which he or his authority supposed had been discovered. Of any other reason than the supposed date and Albert Durer at that date having been at the place named for the assignment of the woodcut to him, Mr. Holt says not a word. But then unfortunately the date, after all, *is no forgery.* The writer of the above positive statement is obliged to acknowledge that the print has not been tampered with. He then, upon the discovery, coolly, as if nothing had happened, starts another theory that the date has to do with the legend only and not with the cut. If he can only give a good reason for this—we will not say opinion—this *ipse dixit*, we shall be glad to give it the attention it deserves. In the meantime, considering that in the long letters in *Notes and Queries*, in which all sorts of wonderful things are fearlessly declared to be proved, not one difficulty is really met nor a single position established, it will be waste of our time and that of our readers to discuss that part of the question further. At the opening meeting of the Archæological Institute, at which Canon Rock presided, Mr. Fuller Russell combated the position Mr. Holt had taken in respect to the Fairford windows, and proved the untenableness of the jots of circumstantial evidence by which he had attempted to make out his case. These were that Albert Durer was the inventor of the particular cruciform *fleur de lis* nimbus which occurs in the *Nuremberg Chronicle* and in books from the Koberger Press between 1490 and 1500, A. Koberger being godfather of Albert Durer. Secondly, that he was the first who portrayed the angel and demon receiving the souls of the two thieves in the Crucifixion. Thirdly, that the lily and sword proceeding from the mouth of our Blessed Lord sitting in judgment were his invention. Fourthly, that as far as Germany was concerned, Albert Durer was the original and first delineator of the meeting of Joachim and Anna, the birth of the Virgin, her presentation in the Temple, her marriage to St. Joseph. First of all he affirmed that they had never been painted before 1500, but finding that this would not do, he, as usual, shifted his ground and inserted the words "in Germany." In the *Standard* of September 24, soon after the promulgation of these claims, a writer pointed out very clearly that if Mr. Holt could prove them all to be true—which, however, was virtually quite impossible—he would still be scarcely a step nearer to anything like proof that Albert Durer painted the Fairford glass, and gave plain examples where far more convincing, similar proof might be given on paper in favour of works which, from other reasons, the judge would know not to be by the artist. But, as a matter of fact, Mr. Fuller Russell, from his own personal experience of foreign galleries, and from the books in his own possession, was able to crumple up every instance. Mr. Westlake had already shown that the subject of the demon and angel was common in Italian art, and that Durer could scarcely have been unaware of it. A volume was exhibited of 1508, by John Knoblouch, in which a Crucifixion occurs, with the two angels. This cut is by Van Gamperlin, a contemporary of Durer, who resided at Strasbourg, who might as well be called the inventor, but the fact is that it is much older. Dr. Roch said that he had an early German painting where the soul of the penitent thief is carried up to heaven by two angels in azure dalmatics, while the soul of the other is being taken off by the devil himself.

Next, as to the lily and the sword, Mr. Russell would have instanced first of all the *Nuremberg Chronicle*, but as Mr. Holt, contrary to all probability as to resemblance to his known works, contrary to possibility according to Mr. J. G. Joyce, F.S.A., if we consider the date, attributed these cuts to Albert Durer, and that notwithstanding the statement in the Colophon, "Michaele Wolgemut at Wilhelmo Pleydenwurf quorum solerti acuratissimaque animadversione tum civitatum tum illustrium virorum, figuræ insertæ sunt." But, says Mr. Holt, figuræ here means portraits, though he would find it very difficult to prove it. Why! figuræ or typi is

the regular printer's word for all sorts of illustrations long and long after Durer's time. Thus "Il Pastor Fido," illustrated by L. Kilian, 1602, has on the title "di bellissime figurae ornato;" and in "Impresa Illustri di diversi," &c., by Camillo Camilli Venetiis, 1586, we have "con le figure intagliata. Biblia Sacra—cum figuris et descriptionibus," &c.: Lugduni, 1567. "De necnon figuris et chorographicis descriptionibus illustrata": Lugduni, 1569. And, as late as 1685, "Philosophia Imaginum figuris elegantioribus ac antea ornata Amstelodami."

If, however, as Mr. Holt would have it, Albert Durer's name was omitted from the Colophon, and the work of the other two carefully limited to the cities and portraits (?) in order that he might at some future time assert his authorship of the larger cuts, how is it that he never did so? He was very tenacious of his rights, as is shown by his complaint against Marc Antonio. But, as the designer of these cuts is disputed, Mr. Russell showed that the detail mentioned was in use long before Albert Durer's time from other sources. First, they occur in a tempera painting at Gloucester, described by Mr. Scharf as a most important specimen of English work of the fifteenth century. Secondly, in a Horæ after the use of London, belonging to Mr. Russell, in which our Lord as Judge is attended by two angels—one (Misericordia) with a lily, the other (Justitia) with a sword. Thirdly, in two important pictures quite within Durer's reach, viz., the triptych by Rogier Van der Weyden the elder, at Beaune, in Burgundy, and the altar-piece at Dantzic, by Memling. This Mr. Holt doubts, though it is dated. Anyhow, whether it be rightly ascribed or no, the supposition of its dating fifty years later is preposterous. The style, and especially the architecture, such as the splendid Pointed Gate of Paradise and the burnished gold armour of St. Michael, forbid any such idea. Mr. Russell expressed his own certainty, from a long study of his works and from comparing it with a beautiful specimen of the artist in his possession, that it was really the work of Memling. The Van der Weyden's masterpiece is also doubted by Mr. Holt, apparently for no other reason than that art critics are not all agreed as to the name. He is known, however, to have painted for Chancellor Rollin, who in 1443 founded the hospital of Beaune; but whether he painted it or no, "as well," says Mr. Fuller Russell, "might Van Eyck's picture at S. Bavon be attributed to Mabuse as this to any painter of the sixteenth century." Next let us take the representations of St. Joachim meeting St. Anna, the Birth of the Virgin, &c. In the "Missale Pariense" (John Prato, 1489) we have both the Birth and Marriage, and vignettes of the meeting of Joachim and Anna; the Nativity, Presentation, and Espousals. The Birth and Marriage occur also in a painting by Van der Weyden in the Berlin Museum, described in the *Ecclesiologist*, 1850. The Nativity is painted in a picture by the Cologne artist, usually called the master of the Lyversberg passion (1463 to 1480), in the chapel of St. Maurice, at Nuremberg, and the meeting of SS. Joachim and Anna in a picture by the same man at Munich.

Mr. Holt also said that the lettering of the scrolls was in the style invented by A. Durer, and always since called by his name; but a comparison of tracings from the windows with the real thing proved that no such thing was the case. And now we come to what Mr. Holt calls his private and particular property, and which he says gave a clinching blow to his theory, viz., the *fleur de lis* nimbus. Now it is not a little curious that, as a rule, Albert Durer in his acknowledged works hardly ever used a nimbus at all; if he represented glory it was usually in the form of rays, either cruciform, as in the Seven Candlesticks of the "Revelations," or round the head and body, as in the lovely Madonna and Child upon a crescent, a trial proof of which is before us. It is not correct to say, as some have done, that he never used the nimbus, for in a woodcut of a Virgin and Child seated, which is also before us, she, with a crown on her head, has a circular nimbus with a scalloped edge, and the Saviour a cruciform nimbus, the limbs being formed not of *fleur de lis*, but of some light branching twigs of foliage. As to this nimbus being particular to Albert Durer, if he ever used it, he only did so as one of the commonest forms of nimbus in vogue. We have before us at the present four instances at least, two in pages from block books whose rudeness would have disgraced Albert Durer even as a child—one in a woodcut representing our Lord in the scarlet robe, attributed to Lucas Van Leyden, and certainly of his time; and another in the "Missale Augustense," by Radholt, 1510—who, by the way, was formerly of Venice. But Mr. Russell's collection makes very short work of this clincher. He showed, by examples, that the aforesaid nimbus was neither confined to the books alleged nor to the time specified. Among the instances shown, were a book by Antoine Verard, 1480; a MS. of about 1450; "Missale Parisiense," mentioned above; "Sermo pro Episcopo puerorum, circa 1496," W. de Worde; "Mons Perfectionis," by the same printer, 1501; Van Gambelin's "Crucifixion," Strasbourg, 1508; "Missale Trajectense," 1514; Martin Luther's sermon, 1523. If out of two not very large libraries so many examples, from so many different places, and of such various dates, could be readily found of this particular detail, we see how foolish must be any attempt to prove the authorship of any work of art upon such fanciful data.

The question, then, of the painter of these windows still depends, as the writer in the *Standard* said it must do, upon the internal evidence of the paintings themselves and documentary evidence, if such is forthcoming. Actual reference to these particular windows in any account is now unlikely to be found, though those whose business or pleasure it is to hunt up old MSS. know that more unlikely things have occurred than the discovery of such a very interesting entry as that would be. Still, the great quantity of papers relating to this great master, or the public records, &c., and church accounts of Nuremberg and Germany, if properly searched, ought at least to furnish some evidence of Albert Durer being engaged in this trade, if he was employed in it to the extent supposed by Mr. Holt. To this question at last Mr. Holt seems to acknowledge that some answer should be given. At the meeting of the Royal Archæological Institute he seemed to fancy that he had quite proved this point—first, because there had been unbroken tradition from the time the windows at Fairford were executed; but, unfortunately, no such tradition can be proved for more than a hundred and fifty years or so. Secondly, that certain modern treatises and dictionaries said so—an argument about as strong as if we were to say "that he didn't." Thirdly, because, if he did not paint glass, how did he employ himself from 1490 or so to 1506, in which year he painted his first picture, though he previously signs himself as "Mahler"? We are not at all prepared to admit that the picture of 1506 was his first, and even if we did we presume that he could not have painted such a picture in so perfect a manner without considerable previous training both in the study of the human figure, in which he so excelled, and in the use of oil colours. Besides this, it is quite certain that he must have had immense practice at this time in drawing to enable him to bring out the marvellous woodcuts and engravings which were issued towards the end of that time. In Marc Antonio's "Life of the Virgin," the date 1506 is given, which we have no doubt is the date Albert Durer wished to be appended, and which denotes the time of the completion of the *designs*, not of the engravings from which they were copied, the earliest date on which is 1509. Mr. Joyce pointed out, in the *Times* of September 23, that much of this time might easily be accounted for. But we can go much further. Has it escaped the notice of Mr. Holt, who was so very hard upon Mr. Waller for taking his crucial tests, by which he compared the drawing of the Fairford glass with Albert Durer's known work from the "Small Passion"—(he supposed that Mr. Waller's acquaintance with the works of the master was confined to that "common work")—has it escaped Mr. Holt's memory, we say, that that most delightful and extraordinary work, the "Adam and Eve," from which Marc Antonio and Raphael seem to have taken the idea of the design for the same subject, which is so celebrated, was published in 1504? The Leeds Exhibition furnishes a curious and instructive instance of the popularity of both these prints. In Gallery J, No. 1,124, was one of the most beautiful majolica plaques which we have ever seen. It is a copy in a fine blue of Marc Antonio's "Adam and Eve," but, as our readers know, the Marc Antonio had no drapery nor fig leaves; the artist, whoever he was (he signs, by the bye, with Marc Antonio's monogram), supplements the designs by the branches of the trees from Albert Durer's engraving. How much practical preparation would Mr. Holt give for the production of such a work? But we do not stop here; there are at least thirty-nine engravings without date, some of which certainly are shown by the style to be earlier works than the "Adam and Eve." Notably so is the portrait of himself as the "Prodigal Son," which was done apparently about the time the Fairford glass was painted. The animals in it are so beautiful as to be worthy of framing alongside of Morland or Teniers. But of this more anon. In 1503 we have two very fine engravings, "The Madonna seated suckling the Infant" being very lovely. In 1504, besides the "Adam and Eve," we have an engraving of the "Nativity," and in 1505 we have three more; so that, as a matter of fact, there was plenty of work to employ Albert Durer during the time in question, though it may not be easy to prove for certain what it was. We now come to the evidence of the paintings themselves. Do they bear the handwriting of the master upon them? Mr. Holt says that he sees Albert Durer in every inch, and in this opinion, to some extent, he is supported by a well-known and talented writer—more celebrated for his happiness of language and expression than for the value or justness of his art criticisms. But we must remember that Mr. Holt also sees Albert Durer's pencil in the "Speculum Humanæ Salvationis," in the *Nuremberg Chronicle*, and the block books—an opinion that will, in the judgment of most persons, destroy the value of his conclusion, and justify in a stronger sense than possibly was intended, his observation at the Institute that "he did not pretend to be an artist." Doctors still differ about the designers and country of the windows, but one thing is pretty certain, *i.e.*, that Albert Durer had nothing to do with them. There are two points which make this as certain as the case admits. No man for his date drew so correctly as Albert Durer. It was simply impossible for him to draw hands and feet badly. But notwithstanding the grandeur of and splendour of colouring, the human figure is singularly ill-drawn in the Fairford glass, the extremities and joints being particularly faulty. It is of no avail, as Mr. Holt did with singular infelicity, to say that these were works of his 'prentice hand. The designer and draughtsman of the woodcuts of the Apocalypse could not have done such bad drawing as is to be found at Fairford. Fancy the artist who had published the "Adam and Eve" in 1504 being unable to draw joints and feet a few years earlier!—the drawing of "Adam and Eve," be it remembered, being on stubborn copper. Never was a more unfortunate comparison made, as Professor Westmacott pointed out, than when Mr. Holt said we might as well compare Stanfield's

scene painting with his finished oils of his later life. The work of the artist is just as apparent in the one as the other, and it is just this point that we miss in the Fairford glass that proves it to have been done by a different man. But Mr. Waller adduced another reason against Mr. Holt's theory, viz., that the animals were lifeless and ill-drawn. This was a point in which Albert Durer particularly excelled, as in the delineation of pigs in the engraving quoted above, which is as early as the Fairford glass. This drawing is evidently by the hand of a master who closely observed not only the form but the ways and habits of animals; there is even the little pig jumping up to get his feet into the trough, and the crowding of the bigger ones to keep out their neighbours, one monster only just being able to get his nose through. The cocks and hens and other belongings to a farmyard are equally well and truthfully delineated. Mr. Waller instanced the ass in "The Triumphant Entry into Jerusalem," but we have earlier and finer drawings in "The Horses," of 1505, and the beautifully-drawn animals in the "Adam and Eve"—puss and the mouse, the parrot, the stag—so fine that Marc Antonio copied it almost line for line. Professor Westmacott and Dr. Roch, who said that the late Mr. Pugin was of the same opinion, strongly expressed their conviction that the Fairford windows were none of Albert Durer's. As this notice has already exceeded the length we intended, we will only touch upon another point which strongly militates against the German originality of many of these windows. The architectural details are of a Perpendicular character very common in England in English glass and wall painting—but never, as far as we know, used by Albert Durer in any single work known to be by him.

We do not pretend to have discovered the artist of these windows any more than those of a large majority of the windows in Europe. There is so little data to go upon that without documentary evidence we believe the thing to be virtually impossible, painting on glass being so entirely different in every respect from ordinary painting and drawing.

HOSPITALS AND THEIR CONSTRUCTION.

THE first grand point which the architect should bear in mind is, that "the object sought in the construction of a hospital is the recovery of the largest number of sick persons to health in the shortest possible time," and to this end everything else is only subsidiary. The ground selected for a hospital should be porous and dry, and should not receive the drainage of any higher ground. Clay soils, and retentive soils generally, should be as far as practicable avoided. It is an error to build a hospital on a steep slope. No doubt by forming a plateau for the building the water from the higher ground may be more or less perfectly cut off from the foundations of the hospital, but the higher ground, especially if it be steep, will stagnate the air just as a wall or a rampart stagnates it. In certain positions it is advantageous to secure shelter from unhealthy winds, but that shelter, be it a range of hills, or walls, or houses, or trees, should always be at a sufficient distance to prevent stagnation of air and damp. If the last point be not attended to, the shelter from an evil recurring only at intervals may be purchased by loss of healthiness at all other times. In short, by keeping steadily in view what the function of a hospital really is, many of those unhealthy conditions which are so frequent in some existing buildings may be avoided in future. In testing the healthiness of the site prior to making a set of plans, an inquiry into the rate of sickness and mortality in the district will afford valuable indications as to the fitness or otherwise of the ground for the hospital. But the architect should not be guided by the mortality alone, for it by no means follows that a district with a low rate of mortality is suitable for a hospital. The nature of the diseases and the facility or otherwise with which convalescence and recovery occur must also be taken into account. The architect must recollect that to the working population time is life, not only to the breadwinner, who is most probably the patient in nine cases out of ten, but to his entire family. Therefore on the architect as well as the doctor rests the responsibility of speedily restoring the poor to health.

The local climate should be healthy to a degree before an architect can with safety recommend the erection of a hospital on any site. There should be nothing to prevent the free circulation of air over the district. There should be no nuisances, damp ravines, muddy creeks, or ditches undrained, or marshy ground close to the spot, or in such a position that the prevailing winds would blow over them to the hospital. The natural drainage outlets should be sufficient and available, as from want of attention to this matter the whole fluid refuse of large hospitals has been allowed to percolate the subsoil within the hospital inclosures for many years.

Having selected the site, the next point is to determine on what principles the building is to be constructed. This is an all-important point, respecting which there have hitherto been no fixed principles recognised. Hence there are very few hospitals planned in such a manner as to be sufficiently supplied with space, light, or air, and further, there is hardly a single building in regard to which it can be stated that it combines the requirements of healthy construction with sufficient facilities for administration or the study of the young medical man. On what basis, then, should the plan of a hospital rest? From what point of view should it be considered? We state unhesitatingly from the ward construction. The first care of the designer of a hospital, be it large or small, is to obtain good healthy wards, and having obtained them on the plan everything else must be made to suit the money and the ground. The means of access, discipline, and administration must bend to the ward, but the ward must never be made to yield to them. In the great majority of cases the main question in hospital construction appears to have been how to get most conveniently in and out of wards and buildings, or how to provide the best offices and residences for the physician, matron, &c.—very proper questions in their place. But the real question is, how the sick are to get well in the shortest possible time, and this is mainly determined by the ward construction. The ward is hence the foundation of a hospital plan, and the ward construction and proportions must be based on the number of cubic feet to be allowed per bed. The new medical regulations have fixed this datum at 1,200 cubic feet, so that the architect, taking that space as the minimum, can govern himself according to the money at his disposal, and increase the cubical space in the ward as much above 1,200 cubic feet as he can afford. It is of vital importance that the space should be properly disposed of, whether the ward should be high, or long, or broad. The usual idea of appropriating space is to have high ceilings, which at a fixed amount of cubic space infers short wards, or narrow wards, or wards both short and narrow. Hence, if the wards be made higher than necessary the sick will be crowded too close together. A large cubic space badly used may involve overcrowding of sick on the ward floor. We would propose to make the breadth of the ward the foundation of ward construction, because a certain breadth of ward is essential for the ordinary working of the hospital. There must be space along the centre for the tables or other conveniences, and also for improved firegrates, which under certain circumstances may be introduced with advantage in the centre of long wards; while at the same time the breadth of the ward should not exceed a certain number of feet, otherwise ventilation by opposite windows, which should always be resorted to when the weather and season admit of it, cannot be efficiently maintained. Keeping these principles in view, if we take the opposite beds at 6ft. 6in. in length 13ft., we may allow 14ft. from foot to foot of the opposite beds, and the ward will thus be 24ft. broad. One of the dimensions of the 1,200 cubic feet allowed to each bed will be 24·2 = 24ft. If we allow 7ft. 3in. for each bed in the length way of the ward, we shall 12 × 7ft. 3in. = 87 square feet as the superficial area for each bed, and 14ft. for the height of the ward. The unit of cubic space per bed will thus be 12 × 7ft. 3in. × 14 = 1,218 cubic feet. It would nevertheless be advantageous to add a foot or two in width to the ward, in order to give more space for tables, &c. Each hospital bed should not be less than 3ft. in width, so that 3ft. being the standard the foregoing dimensions would give a distance of 4ft. 3in. from side to side of adjoining beds, if the beds were equally distributed along the wall. The length of the ward can easily be obtained by multiplying half the number of beds required by 7ft. 3in. Thus suppose a ward is required for twenty beds, then 20·2 × 7ft. 3in. = 72ft. 6in., the length the ward should be constructed. The beds should be arranged on opposite sides of the ward, heads to walls. The number of beds to be placed in a ward should be divisible by 4, in order to prevent loss of corner space. The greatest economy of space would be effected by adopting wards for 4, 8, 12, 14, 20, 24, 28, or 32 beds, beyond which last number we strongly advise no architect to design a hospital ward.

The next question is that of windows, and their number should be equal to half the number of beds. Thus a ward with twenty beds ought to have ten windows, five on each side. The distance between the end wall of the ward and the first window from each corner should be 4ft. 6in. The wall space between every two windows should be 9ft. wide, and the splay of the window into the room should be 5ft. 6in. wide. One bed should stand in each corner, about 18in. from the end wall, and each 9ft. of wall space should have two beds placed in it 3ft. apart. The windows should extend from within 2ft. 6in. or 3ft. from the floor to within 1ft. of the ceiling. In a ward 14ft. high the windows would be from 10ft. to 10ft. 6in. in height.

Every ward in a well-designed hospital requires for itself, or it should have, easy access to the following offices:—a nurse's room, a ward scullery, a water-closet for every ten beds, a urinal, and last—though not least—a bath room. The fitments of these rooms should be well considered by the architect, and a short *resumé* here may probably assist some of our professional friends some day when they are at work on a set of plans for a hospital. The nurse's room should be so placed that a window in the partition will enable the attendant to overlook all the beds in the ward from her chair. A scullery containing a small grate, with an oven and boiler, a table, racks for cups, a well-constructed sink of white glazed earthenware, the drain-pipe of which should be trapped and ventilated if connected directly with the sewer, or it should terminate in the open air at a short distance above a trapped sewer grating or rain water pipe. Over the sink should be two water taps, one for hot and one for cold water. The proper use of this scullery is to have small vessels washed, instead of their being sent to the kitchen, where they may be kept for some time, and the patients be thus deprived of their use. Hot water will be always at hand so as to fill feet bottles, or for fomentations, &c.

Water-closets, one for every ten beds and under, and one for any number of beds exceeding ten, or any multiple of ten, should be provided for. In the large class of hospital the closets should be placed at the end of

the ward furthest from the centre of the building, and in such a position that the external air can play freely around them. They should in all cases be cut off from the wards by a well-ventilated lobby. A fixed bath adjacent to each ward is absolutely necessary. The bath, of course, would be supplied with hot and cold water, but a tube should be attached to the tap, which would supply a slipper bath if required. In the floor of the bath-room a small trapped pipe will be of great service in removing the water which must often be thrown out of the bath. This last is a small point, but it is well worthy of being remembered by men who design such places. How seldom one sees it either in a hospital or even a public bath-room. Earthenware baths glazed inside are much better for hospitals than even the more expensive enamelled iron now so much used. They are more easily cleaned and keep the temperature more equal than those of metal. For ablution rooms fixed basins with plugs and washers are best.

COMPARATIVE STRENGTH OF WROUGHT-IRON TUBES.

AT a time when a large share of public attention is being directed towards every feasible method of overcoming the watery barrier separating Albion's chalky cliffs from the Gallic shores, it may not be *mal à propos* to briefly consider what would be the most suitable form that a bridge should possess, supposing for the moment that particular medium to be adopted. In consequence of the peculiar circumstances attending the case, the tubular form, from its great rigidity, perfect compactness of parts, and from the success which has attended its erection in a similar situation over the Straits of Menai, appears to offer many advantages over other types of bridge construction. Generally speaking we should be disposed to give the preference to the open web or lattice principle, from its superior lightness and elegance of appearance; but the present is just one of those special instances which occasionally arise, and justify a departure from that which would otherwise be the course to adopt. It must not be forgotten that one of the chief objections to the tubular type—namely, its great weight and mass of metal, in this case falls to the ground; in fact, it becomes an argument in its favour. As the spans must exceed any that have yet been erected, and cannot well be less than 1,000ft., a very large amount of metal becomes absolutely necessary in the construction of the bridge, and a great insistant weight, so long as it is also serviceable in carrying the live load, is a positive advantage. Taking into account that the maximum force or impact of the wind may in hurricanes attain to so much as 70lb. per square foot, it is evident that the *vis inertiæ* of a structure placed at an elevation of at least 120ft. above high water mark can scarcely be in excess of what may be required of it. In this respect the tubular girder, with its solid sides and booms, is infinitely superior to its open web rival. There is, in fact, no question that the former is the stiffest description of bridge that can possibly be constructed. We do not mean to assert that a lattice girder would not answer in the same situation, but we maintain that it is not the form best adapted to meet the peculiar exigencies of the case.

Assuming for the moment that the tubular principle is that selected, the next step is to investigate the precise shape in which it is best calculated to resist the various strains brought upon it. All tubular girders may be reduced to three classes—the circular, the elliptical, and the rectangular. A square tube would, of course, be only a particular example of the rectangular, in which all the sides become equal to one another. It is worthy of remark that the square or rectangular sections were those which first suggested themselves to the mind of Stephenson when he was engaged in devising the present means of crossing the Straits of Menai. On the other hand, it was argued, and with much justness, that the circular and elliptical tubes were well adapted to preserve their shape, to effectually resist the separate strains of compression and tension induced upon their upper and lower flanges, and, moreover, offered but little opposition to the force of the wind. This latter power was completely the *bête noire* of many interested in the successful execution of the great project, and terrible results were prognosticated by its enemies of what it would accomplish when the tubes were in course of being fixed. Fortunately, all these predictions proved utterly groundless, and the actual effect of the most violent storm has been determined by accurate measurement to produce little or no lateral motion or deflection upon the Britannia Bridge. The experiments carried out by Stephenson with regard to the strength of circular and elliptical tubes cannot be said to have been at all satisfactory or conclusive. The plates composing them were exceedingly thin, in some cases not exceeding the twenty-fifth part of an inch, and the mode of riveting adopted was of a very unscientific character, the joints not even being protected by a cover or wrapper. As might have been readily imagined, in consequence of the tubes possessing not the slightest lateral rigidity they were soon drawn out of shape, the circular form merging into an oval or elliptical, and the latter suffering a further elongation in the direction of the major axis. The proper course would have been to have carried out some experiments upon these tubes, with thicker plates, better riveting, and better designed joints, and then have compared the results with those of the other form. But as the rectangular shape appeared to offer, on the whole, superior practical advantages, the circular and elliptically shaped examples were abandoned, and attention directed towards perfecting the dimensions and proportions of the former kind. The alteration which took place in the form or section of the tubes might have easily been either altogether prevented or at least greatly retarded by the introduction of suitable diaphragms and internal bracing, and it was rather an unpardonable oversight in those who had the conduction of the experiments to have omitted means so simple and manifest of increasing the strength. Thick plates constitute the best protection against buckling or other change of form. The best proof of the unscientific and inefficient manner in which the circular tubes were constructed is that, although the iron was of a quality fully capable of sustaining a tensile strain of twenty tons, yet the bottom fractured when the strain was not more on the average than thirteen tons. After abandoning all further investigations with respect to the circular and elliptical forms those upon the rectangular were prosecuted with great energy, and the results gave a considerable accession of strength over those of their predecessors. So far as precedent is concerned the rectangular tube certainly appears to have the advantage over its rivals, but it is to be hoped that were this form of bridge seriously contemplated for crossing the Channel it would not be ultimately adopted until the others had been subjected to a series of comparative tests, for the purpose of determining whether they are really inferior in strength and rigidity. Among the practical advantages possessed by the square or rectangular section is that of requiring the smallest superficial internal contents. It is easily perceived that in the latter the roadway can rest close down upon the bottom of the tube, whereas in the circular and elliptical it must form a chord of the circle, and, consequently, the extreme height of the tube must be greater than in the rectangular section. A glance at the diagram will illustrate our meaning, the letters in each figure having the same signification. Thus, in a tube carrying a single line of rails the rectangular fig. A B C D will represent the least superficial contents or sectional area required, in order to afford room to clear the rails underneath, the funnels overhead, and the carriages at the side. The line L M represents the level of the top of the engine funnels, and N O that of the top of the rails. The fig. E F H K is the space contained between the centre lines of the cross sections of the engines. In adopting the rectangularly-shaped tube we perceive that we can reduce the form to the minimum sectional area demanded, while there is a manifest loss of area in the circular shape both at the sides and bottom. The elliptically-shaped tubes, shown approximately in fig. 1 by the dotted lines A C, B D, save some space at the sides, but are not so economical as the rectangular. Upon the whole, therefore, unless fresh experiments evince that the cylindrical form possesses some advantages not yet discovered, the preference, judging from precedent and practical knowledge and results, must be given to the rectangular form.

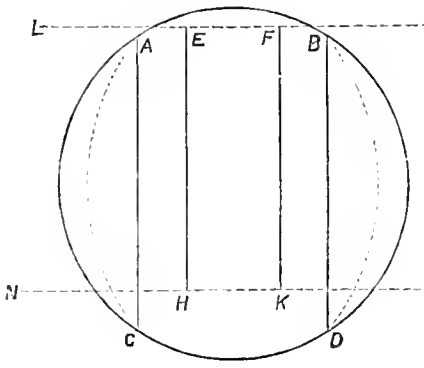

FIG. 2.

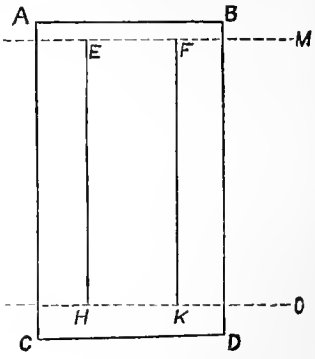

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

ON Monday evening last Mr. Charles Barry presided over a large attendance of Fellows and Associates. Mr. James G. Smither, of Colombo, Ceylon, was duly elected as a Fellow, and Messrs. William J. Marsden and Reginald E. Worsley were elected Associates. Mr. Seddon read a letter from Mr. Smirke, who sent an interesting Norman capital, found in the Temple in some recent works there, having all the freshness of new masonry, and having been apparently only used as rubble. It was probably twelfth century work. Mr. Seddon also announced that a report on a design for the new Norfolk Lunatic Asylum had been received from Mr. R. M. Phipson, the architect. This was a good precedent for architects to send similar reports to the Institute for the general information of the profession. The chairman then called upon Mr. A. H. Layard, M.P., to read the paper for the evening.

ON MOSAIC DECORATION.

Mr. LAYARD, after stating that his paper was supplementary to that read before the Institute by Mr. Digby Wyatt, in March, 1862, referred to

the attention he had paid to fresco painting, and to the disappointment he felt at the failure of that art in this country from climatic influences, as seen at Westminster and All Saints', Margaret-street. He next referred to the prejudice existing against the use of decoration in ecclesiastical and secular buildings, out particularly the former, although a great deal had been got over. Disappointed with the failure of fresco-painting in this country he had turned his attention to mosaic as a means of supplying the place of fresco. The art of putting together small cubes or tesseræ of different substances, so as to form patterns and figures either in monochrome or in various colours, was very ancient, being known to the Egyptians, Assyrians, and Babylonians. Mosaic was applied to the decoration of walls and pavements, and was extensively used, especially for the latter purpose, by the Greeks and Romans. Owing to the durability of the materials generally employed, such as hard marbles and porphyries, enamels or glass, and terra cotta, mosaic has defied the ravages of time probably more effectively than any other architectural decoration. Pictorial mosaic on a really large scale was first used for the decoration of public buildings during the later days of the Roman empire and during the supremacy of Byzantium. Mosaic took its chief development after the spread of Christianity, and in the decoration of Christian edifices, and may, therefore, be called an essentially Christian art. The most magnificent examples of ancient times were to be found in the churches of Christian Rome, Constantinople, and Ravenna. The chief features of Christian mosaic are the vast extent of wall surface to which it was applied; its most frequent use on domes, apses, and curved surfaces; and the representation of figures and ornaments on a gold ground, although a gold ground was not always used. The extreme richness of this mode of decoration, and its grand and solemn character when used in large masses, made it especially applicable to religious purposes. Though generally used in the embellishment of churches there are several recorded instances of royal palaces having been profusely adorned with it. A vast mass of ancient mosaic work has perished; no small amount in the East is still covered with whitewash and plaster. There seems to have been scarcely a church or baptistery of any importance built within the precincts of the Byzantine empire that had not more or less mosaic decoration. The fashion spread across the Alps, and Charlemagne decorated his basilicas and palaces with mosaic. The general use of mosaic led to improvements in the materials employed. Marbles and porphyry could no longer be exclusively used, and earthenware did not promise the required durability. Enamels or vitreous substances were mixed with them, and the art of enclosing gold leaf between layers of glass—a very difficult one, requiring great nicety of manipulation—was discovered. Among the most remarkable of the early mosaics now preserved are those of St. Sophia, a church at Salonica, the Baptistery of Constantine at Rome, the Baptistery at Ravenna, and of St. Maria Maggiore at Rome. Unfortunately few of the early mosaics at Rome and Ravenna are free from considerable restoration, and their original character is in many instances much destroyed. Frequently these restorations are made with mere coloured plaster. Among the edifices which furnish the best examples of mosaic decoration and are most deserving of study with a view to the use of mosaic in this country, may be mentioned St. Mark's at Venice, the Capella Reale at Palermo, and the basilicas of Ravenna. These are to be taken not in order of date, but according to their importance as illustrating mosaic decoration. St. Sophia's is excluded, because the mosaics on its walls are for the most part concealed by plaster, and have been so covered since the Turkish conquest. St. Mark's, taken as a whole, is the most perfect example of internal decoration in the world. Details may be more beautiful in other edifices, but nowhere else will be found an example of one noble and grand conception so thoroughly and completely carried out. It furnishes, too, the fullest and most valuable chapter in the history of mosaic, for it comprises specimens of mosaics extending over a period of from between the eleventh and twelfth centuries to the end of the seventeenth, and consequently embraces a variety of styles and shows different modes of employing mosaic. Every square foot of the church is covered with mosaic work, except where the richest marbles panel the lower parts of the wall. There is no uncovered or naked space. The eye is completely satisfied. Nothing looks unfinished. A visit to this edifice would impress one with the feeling that if we are to have decoration in our sacred edifices on a large scale, so as to add to their religious character, mosaic is the most appropriate of all decoration. The lustrous surface of the enamels, the large masses of gold ground, the richness of the colour, produce an infinite variety of the most beautiful effects, ever changing as the sun changes its place. St. Mark's, is never the same. Enter at any hour of the day, in summer or in winter, and whether the sky be clear or overcast some new and unexpected effect will surprise and delight. The singular harmony, notwithstanding the abundant richness of the gold grounds which prevail throughout the decoration of St. Mark's' is owing to its completeness. Any whitewash or plaster, or blank undecorated space such as one sees in our churches, would have been an eyesore, and would have marred the marvellous beauty of the whole. When thus complete, decoration, whatever may be the wealth of gold and colour lavished upon it, is never vulgar or tawdry, but, on the contrary, when a just balance is preserved in them, it is sober and harmonious, and can be made eminently subservient to religious purposes. It is only when decoration is introduced as if it were something not forming an essential part of the building itself, but only put there for show, and as if too precious except to be doled out with a niggard hand, that it becomes vulgar and tawdry, and appears inconsistent with the objects of a sacred edifice. St. Mark's taught us that it was especially necessary to avoid white spaces, and especially plaster, when materials so rich as mosaics are employed. In St. Mark's could be studied the best mode of employing mosaics and the style best suited to our churches. In this very museum of mosaic decorations are to be seen specimens of all styles and descriptions of work. The most ancient are simple figures on a gold ground, probably the work of Greek artists, or if not, certainly copied from them, and most properly called Byzantine. Perhaps the most perfect specimen of mosaic decoration after St. Mark's is the Capella Reale, or as it is frequently called, the Capella Palatina in Palermo, built in 1132, and the mosaics of which were finished about 1143. They are all of the same period. The decoration of this building is complete. In the basilica of Monreale, magnificent as it undoubtedly is, and superabundantly rich as it is in mosaics, the effects are less solemn and religious than those of St. Mark's; still it is a glorious building, and furnishes to the architect an invaluable collection of beautiful ornaments of a particular period and style, the church having been entirely built and decorated towards the end of the twelfth century. It affords, too, an important example of the use of mosaics for pictorial purposes on side walls. The colossal form of the Saviour on a gold ground in the semi-dome over the central apse, has a grand and imposing effect, and is a fine example of the manner in which this architectural feature in a church can be appropriately decorated with a single figure. Unfortunately, the ancient basilicas of Ravenna have either been allowed to fall into decay or have been so much changed by modern restorations and alterations that we can no longer judge of the effect which the mosaics they contain must have produced when the whole ornamentation of the interior was in complete harmony with them. What is usually called the "Jesuit" architecture of Italy—that vulgar Renaissance which is so offensive to good taste and so utterly opposed to all solemnity and true religious feeling—introduced the fashion of breaking up the interiors of ancient churches by the introduction of side chapels, and of vast altars composed of columns, cornices, and pediments of marble of every hue, piled up without any reference whatever to the surrounding architecture, or without any pity for the frescoes and ornament which can have adorned the walls. The original simplicity and symmetry of almost every sacred building of any antiquity in Italy was thus destroyed. Most fortunately St. Mark's, for various reasons, has been spared, and remains both in ornamentation and form nearly as it was intended to be by its builders. In the basilicas of Ravenna we can only judge of each mosaic as an individual example with reference to the actual work and the capabilities of the material. We can form no adequate conception of the general effect which it was calculated to produce as a portion of the general decoration. The richness and harmony of colour are neutralised by the vast spaces of plaster and naked walls by which, in most instances, these mosaics are surrounded. But in themselves they are deserving of the most careful study, as belonging to the best period of early Christian mosaic art. They are specially valued for the interest attaching to some of the finest examples of the treatment of pictorial mosaic and of the technical qualities of the material. As an example of external decoration in mosaic may be mentioned the Cathedral of Orvieto. To judge of the full effects of the mosaic pictures which adorn its richly decorated façade it must be seen from a distance. Standing majestically on a platform supported by precipitous cliffs rising out of a wide valley, it is admirably suited to the display of a richly-ornamented façade. The mosaics, which are modern, are not of the best style, and are too pictorial for the architecture unless seen from afar. Still the effect is very gorgeous, especially on a bright day. Mr. Layard would hesitate, however, to recommend similar decoration for imitation in this country.

If mosaic can be used effectively and advantageously in sacred edifices, there is no reason why it should not, with equal propriety, be employed in secular buildings. All that is required for this purpose is a knowledge of the principles which regulate its proper application, and of the capabilities of the material. In many respects mosaic is preferable to fresco for decoration, especially in our climate, even without reference to the atmospheric influences upon wall painting. It is more durable, more lustrous, more effective when employed at a considerable distance from the eye, far richer, more brilliant (especially when gold grounds are extensively used in the subdued light of our climate, and, lastly, in case of injury or deterioration from dirt or other causes, it can be restored and cleaned without any detriment or loss of character to the original work. Fresco painting and mosaic have, however, distinct and separate attributes and capabilities, and when both can be employed under equally favourable conditions, as in Italy, they need not interfere with one another. The minute and elaborate mosaic work, chiefly practised at Rome, is intended rather for the reproduction of easel pictures and altar pieces than for architectural decoration. This is to be avoided by the architect. Legitimate mosaic decoration, like all true architectural decoration, should, in the very first place, be made subservient to the architecture, or rather it should be made essentially a part and parcel of it. The truly great architect will devise and superintend the decoration of his own building, even, if possible, to the minutest details, for nothing adds more to the effect of an architectural monument and to its grandeur and nobility of character than the feeling that one clear, well-defined, and lofty conception pervades the whole of it. When the identity of conception is apparent in a building, however inferior it may be in certain details to another edifice in which homogeneity is wanting, it will always be far superior to it in the general effect which it will produce. In order to make mosaic decoration harmonise well with architectural lines and forms, all the best designers of mosaic have sought to give their cartoons a certain conventional and architectural character, and have avoided any attempt to make the mosaics look like pictures in oil. As from the nature of mosaic (tesseræ placed together with more or less precision), it is best seen at a distance, it should be used, especially when pictorial, at a certain height from the spectator. There are no mosaics in St. Mark's less than about 10ft. from the pavement, and the greater number are at a considerable elevation. Consequently, distinctness of outline, not only in the figures themselves, but in their extremities and parts is required. Each figure should stand out boldly, and not interfere with other figures when grouped. For this reason the best mosaicists of the best periods of the art generally preferred the processional treatment of their figures. Any attempt to produce different planes of distance (which require, to be properly defined, all the subtle tints of the painter's palette), should be avoided. The outlines should be distinct, well-defined, and marked somewhat heavily, their darkness and thickness being regulated according to the elevation of the mosaic. This rule applies to both pictorial and purely decorative work. Reference should be specially had to the style of architecture of the building, always, however, remembering that although the general arrangement of lines and treatment of the subject may be varied to suit it, yet that whether mosaic be introduced into a Classic, Gothic, or Renaissance edifice, the general laws which regulate its use are the same. In order to increase its effect,

almost all good pictorial mosaic is surrounded by a band of appropriate ornament in the same material, the width of which depends upon the elevation and position of the mosaic picture. The design for mosaic, whether pictorial or simply decorative, is essentially the business of the architect, and unless he makes it himself, or causes it to be executed under his immediate direction, he will never produce a really great architectural monument, if mosaic decoration is to be a prominent feature in it. Architecture is the noblest of all arts, for when rightly understood, sculpture and painting become her handmaidens. When they were so, the most beautiful and perfect edifices were produced, whether in Greece or Rome, in Italy, or in more northern climes. The architect who takes this lofty view of his profession, and educates himself to carry it out, will erect the greatest monuments and earn the highest fame. Although the chief merit of the mosaic must depend upon the designer of the cartoon, much is left to the skill and judgment of the mosaicist who executes it. Much effect may be produced by a judicious selection of tesseræ of different sizes for different parts, by the mixture of tints in large masses of one colour (such as a gold ground), so as to avoid monotony of tone, and by the dexterity with which the arrangement of the tesseræ is made to follow leading lines and undulations of flesh or drapery. The intervals between the tesseræ must be regulated according to the distance from which the mosaic is to be seen, and can also be made to contribute to the general effect. These things, and the proper selection and matching of the tints, form the duty of the mosaicist.

It is to be regretted that mosaic had not been introduced into England when the decoration of the Houses of Parliament was commenced. It is to be hoped that it is not too late to introduce it into the building, which is eminently calculated for this mode of decoration. It is to be deplored that the noble idea of making the walls of the House of Commons record the history of the country has not been fully carried out, principally owing to the failure of the materials employed. It will be a national loss if the fine wall pictures of Mr. Maclise should perish, whether regarded as monuments of the genius of the painter or as most careful representations of great events. Had they been executed in mosaic the skilful touch of the master would doubtless have been missed, but designs would have been preserved worthy of him, and he would have been enabled to employ the years that have been taken up in the actual manual labour required in such vast works in preparing other cartoons for the completion of the decoration of the hall, in two panels alone of which the battles of Trafalgar and Waterloo are now represented. The works of some of the principal painters of our time, executed at no small cost to the nation, will perish in all probability within a few years, and our only chance of preserving any memorial of them is by reproducing at least a portion of them in mosaic. We have rising up around us museums, picture galleries, public offices, courts of law, townhalls, railway stations, and other edifices. Each of such buildings might be made to contribute towards the elevation of the public taste by appropriate pictorial decoration in mosaic. But the architect hesitates to fill up the blank spaces in such buildings with frescoes, because he cannot satisfy himself that they will resist the effects of our climate. Judging from the manner in which, in Italy and the East, mosaic (both when used externally and internally) has defied the ravages of time and weather, we may infer that mosaic of good quality is precisely the material which will suit our climate and atmosphere. In our museums and picture galleries (with the exception of the South Kensington Museum, where a most praiseworthy and, on the whole, successful attempt has been made to introduce ornamentation on a large and complete scale), we have hitherto been sadly deficient in rich and appropriate decoration. And yet the value of a work of art, and the impression it is calculated to convey, are very much enhanced in the public mind by the beauty or magnificence of the building which contains it—like a jewel which gains by a rich and appropriate setting. Our National Gallery, for instance, is a disgrace to a great and civilised people. Its dirty floor of common boards, its coarsely papered walls, its undecorated ceilings, its mean internal approach have unquestionably a tendency to depreciate in public estimation the value of the treasures which it contains. Our pictures crowded on the walls of such apartments look as if they were hung for approaching sale by auction. Thousands who visit the National Gallery, and for whose instruction and elevation its contents are partly intended, leave it without any adequate notion of the worth and beauty of what they have seen, merely because they cannot believe that things of real value can be so poorly cared for. There is something elevating and refining in rich and beautiful ornament when introduced into a public building, and the working classes feel the influence of it.

In exterior decoration, gold mosaic can be used as a ground to bas-reliefs, whether figures or ornament, in white marble and other materials. The Byzantines and Venetians were well aware of its worth for this purpose, and of the singular beauty and delicacy of its effect. There are some charming examples in the *facade* of St. Mark's. The statues on the exterior of the church of Or St. Michele at Florence were for the most part lined with gold mosaic. An important consideration in the use of mosaics in England, and especially in London, is the facility with which dirt and discoloration produced by smoke and soot can be removed from its surface, either by simple washing or by the employment of an acid, without the least detriment to its brilliancy. Some mosaics at Ravenna, dating from the fifth century, have been cleaned and are as bright in colour as when first executed.

In England we have never had a school of mosaicists. The fine ancient mosaics that we possess, such as those in Westminster Abbey, were executed by Italians. Mr. Cole attempted four or five years ago to found a school of workers in mosaic, who were to employ tesseræ of terra-cotta, or ceramic tesseræ, instead of enamel. Some creditable specimens were produced by Messrs. Minton, and Messrs. Simpson and Co., but the attempt was not altogether successful. For certain purposes these ceramic tesseræ are sufficiently effective, but they lack the richness, brilliancy, and luminous quality of enamel: reds and purples cannot be produced, and the effect of the gold cannot equal that of the Byzantine mosaics. Their durability is also questionable. In repairing the mosaics of St. Mark's it has been found that whilst the ancient tesseræ in enamel are perfectly preserved, those in terra-cotta and other materials have either perished or greatly suffered. Mosaics in enamel have been executed by several eminent firms in this country. Among these are some full-length figures at the South Kensington Museum by Messrs. Rust and Co. Some of the enamels used were made by Messrs. Powell, of Whitefriars, but the greater part came from St. Petersburg, where is a well-known manufactory of mosaic. In Italy the traditions of the workers in mosaic have been handed down through centuries, but, as the numerous restorations of mosaic work testify, the art has degenerated. A few years ago Lorenzo Radi, a glass-blower of Murano, effected great improvements in the manufacture of enamel mosaics. Dr. Salviati, a lawyer of Venice, was attracted by Radi's work, entered into an agreement with him, and opened an establishment at Venice for mosaic work, obtaining artists from Rome to instruct Venetian youths in the art. In former times mosaic work having to be executed on the walls required considerable time and labour, and was consequently very expensive. The mosaicist had to copy the cartoon on the wall itself, fixing the tesseræ one by one in the cement prepared to receive them. Dr. Salviati avoided this by teaching his workmen to execute the cartoon on the reverse side, the face of the mosaic being downwards. The tesseræ are fastened with common paste to sheets of coarse brown paper, on which the cartoon is traced. When the work is finished it has only to be fixed with cement upon the wall destined to receive it, and the brown paper is removed from its face. The process requires considerable skill, especially when figures have to be executed, but is perfectly successful. It cannot, however, be used when great delicacy and extreme nicety of work in the production of tints are required. Dr. Salviati's attempts at the revival of mosaic work have met with most success in England. His first important commissions were the decoration of Wolsey's Chapel at Windsor, and the Albert Memorial at Hyde Park. These furnish excellent examples of what mosaic work for internal and external decoration should be. Mr. Layard hoped that Mr. Penrose, the architect of St. Paul's, had not relinquished the idea of carrying out Wren's original design of decorating the interior with mosaics. Abroad, the principal commission obtained by Dr. Salviati was that for the complete restoration of the mosaics at St. Mark's at Venice, for which a contract had been entered into extending over fifteen years. In order to sustain an industry of so much importance, a few English gentlemen have come forward with capital, and Dr. Salviati's establishment has become an English company under his artistic direction. Mosaic, both pictorial and simply decorative, not only can be but ought to be employed in this country. Care should be taken in the selection of the cement. That used by Dr Salviati has been tested by Mr. Gilbert Scott and other eminent architects, and approved of by them.

The cost of mosaic depends principally upon the quality of the work, the distance from the eye at which it is to be placed, the predominance of figures, ornament, or simple ground, and the prevalence of certain tints. Reds and purples are the most expensive tints. The gold mosaic, and especially the silver (which is even more difficult to obtain than the gold), is more costly than common tints. As an indication of the requirements of a mosaic establishment, Mr. Layard stated that in order to execute the cartoons which had been entrusted to Dr. Salviati, nearly 1,500 tints had been brought together. Any quality or tint of gold may be obtained by darkening or lightening the colour of the glass upon which the gold leaf is laid, or by using a film of coloured instead of transparent glass over it. The brightness of the gold may also be deadened by roughening the outer surface of the outside film. Taking the various qualities of mosaic which may be fitly used for decorative purposes, the prices would vary from about 30s. the square foot for the coarsest work to £4 (or, at the utmost, £5) for the finest. This includes the fixing, but not the price of the cartoon. After showing that these prices, when compared with the cost of frescoes, are very moderate, Mr Layard concluded by commending the subject of mosaic decoration to the attention of English architects.

A long discussion ensued, in which Messrs. Digby Wyatt, G. E. Street, Aitchison, T. Hayter Lewis, J. P. Seddon, Fergusson, and G. G. Scott (who occupied the chair during the discussion) took part. A vote of thanks having been accorded to Mr. Layard for his paper, that gentleman briefly replied to the various points raised, and the proceedings terminated.

THE BUILDERS' BENEVOLENT INSTITUTION.

THE twenty-first anniversary festival of the above Institution was celebrated on Thursday week, at the Freemasons' Tavern, Great Queen-street, Lincoln's inn-fields; Mr. George F. Trollope (president) in the chair. There were 250 friends and subscribers present. After the usual loyal toasts had been duly honoured, the chairman proposed the "Builders' Benevolent Institution," and set forth the objects of the Institution—viz., for giving relief and granting pensions to decayed members of every branch of the building trade and their widows; also for affording temporary relief to workmen in case of accidents. He pronounced the Institution as being in a very satisfactory state; but the directors had this year deemed it prudent to forego the usual election of pensioners in the autumn. Mr. W. R. Rogers, in support of the toast, having shown the peculiar characteristic in the trade, how, from a wealthy position, builders might—not by any fault of their own, but by vicissitude—be cast down, asked the friends and subscribers to continue and further their assistance, as there were many of their poor brethren anxiously waiting to become recipients of the charity. In August last, the number of pensioners on the funds was 48. The remaining toasts were:—"The Chairman and President," proposed by Mr. George Plucknett; "The Patrons, Vice-president, and Trustees," coupled with the names of Mr. Thomas Cozens, the founder of the Institution, and Mr. John Thorn, proposed by Mr. Crockett; "The Treasurer" (who, in reply, stated that the donations and subscriptions that evening amounted to nearly £500, that the funded stock now stood at £15,000, and that he hoped that in a few years the amount of the annual pension would be increased from £24 to £30); "The Architects and Surveyors," responded to by Mr. Franklin; and "The Directors and Stewards," to which Mr. Wilfrid Nicholson replied. Mr. J. Bird, the secretary, stated that there were 16,000 persons connected with the building trade, and doubtless the Institution only needed to be better known to receive still greater support.

ARCHITECTURAL ALLIANCE.

REPORT OF THE DELEGATES FROM THE ARCHITECTURAL ASSOCIATION ON ARCHITECTURAL EDUCATION.

To the Members of the Architectural Association.

GENTLEMEN,—At the last meeting of the Architectural Alliance, the subject of architectural education was suggested as a fitting theme for inquiry and discussion among the various societies forming part of the Alliance: and your delegates have drawn up the following report to be submitted at the next meeting of the Alliance, in May, which they now bring forward for your consideration. In order to facilitate the inquiry the subject has been divided under four heads:—

1st.—Architectural education as now existing in England and abroad.

2nd.—The best system of architectural education to be established in England.

3rd.—The opportunities which actually exist for extending the sphere of architectural education.

4th.—How far these can be modified and added to so as to arrive as nearly as possible at the ideal scheme set forth under Head II., and what provisional system should be recommended till the suggestions under Head II. be fully carried out.

HEAD I.—EXISTING ENGLISH AND FOREIGN EDUCATION.

In England, as a rule, the would-be student comes straight from school, where his attention has been confined, more or less exclusively, to the ordinary acquirements of a classic education, with little or no knowledge of drawing, and with such a smattering of physics and mathematics as is almost entirely useless. He is articled to some architect for a period of from three to five years, who gives him the run of his office, which means, that he is to pick up as much information as he can by working on the regular office drawings; and by dint of so doing, of copying letters, specifications, and tracing drawings, acquire by the longest possible process the practice of an architect's profession. If intelligent, he is able before the end of the second year to work out drawings from the sketches of his principal, and thus acquire secondhand the facilities of copying old work if in a very good office, or of mutilating it if in a bad one—designing is out of the question. In pointing out this course, it must be understood that it is not in all offices that the student has to shift for himself; but even when it is not so, the principal finds sometimes the greatest difficulty in suggesting how and where the best information is to be obtained; and we all remember when Mr. Scott brought forward his scheme of art education he himself said, "That he was entirely unable to point out to his pupils, or even to his own sons, any means of obtaining true artistic training but the most accidental and irregular."

In Paris, the student on leaving school enters one of the Government drawing schools ("Ecole de Dessin"), where he is taught freehand drawing from models geometrical and architectural drawing. At the same time he follows courses of instruction in mathematics and descriptive geometry. Towards the end of the first year (after leaving school) he enters a studio. A studio is a large room fitted with drawing-desks, where a number of students assemble together to draw and work out their own designs, under the supervision of an architect professor, whom they choose, and who, in consideration of the 20f. a month they each pay during the time they work in the studio, pays for the room, and gives them advice, coming three or four times a week, stopping about two hours and going round to each student in succession. In the studio, the student's attention is first turned to architectural drawing, the delineation of the Orders to a large scale, the projection of shadows, and the laying on of flat tints in Indian ink and colour. As a relief to this kind of study he commences designing, working out plans, sections, and elevations, and making free use of books; in fact, almost copying at first, and having throughout the advice of the professor and of his fellow students. In two years, or less, from the time of leaving school, he presents himself for admission into the "Ecole des Beaux Arts," and passes an examination in mathematics (as far as simple equations), logarithms, descriptive geometry (elementary and the intersection of cones, cylinders, &c.), drawing from the round, and architectural design. If admitted during the first year he follows a course of lectures in mathematics, physics, construction, perspective, &c., working out at the same time in the studio special designs in wood, iron, and stone, writing specifications, and giving all the details of ordinary floors, roofs, &c. In all these subjects, as well as in those above mentioned, on which lectures are given, he has to pass examinations. In the second year he begins architectural design proper, his attention being turned more specially to composition and proportion. Three or four years is the time usually spent in the school. If the student intends to take a high position in his profession he works longer, and the Grand Prix de Rome or even admission as one of the ten competitors for it each year, is the great object he strives to attain to; all this while working in the studios, except when competing for the Grand Prix, the designs for which are entirely done in rooms in the school. It will be seen, therefore, that the student devotes a much longer time to learning his profession than we here in England think necessary; and there are many to whom their parents could not afford support for so long. (We should, however, remark that no premium is ever paid, that the expenses of a studio are small, and that the school instruction is gratuitous.) There are many students, therefore, who not having means at their disposal, work at intervals in the office of some professional architect on his office drawings, receiving so much per hour (from 1f. to 3f.), and thus contrive by working for a little over half the year and in the evening to send in designs regularly to the "Ecole des Beaux Arts," until they have arrived at such distinction as to give them a position equal to their merits.

In consequence of some abuse which had crept into the Ecole des Beaux Arts and its direction, a new school called the "Ecole Centrale d'Architecture" was established four years ago, under the auspices of M. Trelat, an engineer. The results of their work may have been seen lately in the Kensington Museum. They were very poor both in drawing and in composition. In its practical element, however, this school is worthy of our consideration, and we may also be able to suggest where its artistic element was found wanting. The prescribed course of studies lasts over three years, three months in each year being allowed for vacation, during a portion of which time the student is expected to draw and measure ancient buildings. The subjects taught are:—First year—geometry (elementary and descriptive); the "coupe des pierres" (theory of stone cutting); trussing of girder beams, &c., strength of materials; ventilation, acoustics, and mechanics; chemistry, history, geology; sanitary science and natural history. Second and third years—perspective and projection of shadows; applied mechanics; machinery used in building, theory of architecture; comparison of style; construction; specification, estimating, &c.; political economy and architectural jurisprudence; and, during the whole of the three years, drawing and design in the three studios attached, under the direction of professors, with frequent examinations in the subjects of the lectures above cited.

In Prussia the student comes from the university or school with a fair knowledge of drawing, and of physics and mathematics. He first enters the office of an architect for one year, where he picks up what he can, as in England. He does not pay anything, his knowledge of drawing and descriptive geometry placing him in a position to be able to render assistance of value in return for the privilege of being there. He has then to pass a slight examination, and studies in the academy for two years. His attention there is turned to all the theoretical and practical points of the profession. He copies drawings made by well known architects—if at Berlin chiefly Schinkel's—and divides the time devoted to drawing and design between making these copies and the composition of original designs (which, as a matter of course, are more or less adaptations of what he has learnt in copying); he attends lectures on physics, mathematics, construction, supply of water, ventilation, and the principles and practice of estimating and writing specifications. At the end of the second year he passes an examination, and takes the title of bauführer or inspector of works. If he desires to take a still higher position, he gets appointed to some government building as an inspector or clerk, receiving a nominal salary for three years, and then enters the school a second time to study for two years more the higher parts of his profession, at the end of that time passing an examination (and an exceedingly stiff one) which gives him the title of Baumeister (master of buildings) or architect, and [illegible] either become a governmental architect or practise on his own account.

In Vienna the student follows a course of studies in the academy, where there are Gothic and Classic professors [illegible] class. In many cases both these [illegible] are followed, one after the other; lectures are given also, and examinations held in the various theoretical and practical subjects of our profession. A new system of study has been lately introduced here which is worth noticing. The senior students of the school make excursions with a professor, some twenty of them at a time, two or three times a year, for a period of a fortnight or three weeks. They take one or two important buildings in the district, and measure them, taking it in turns to sketch [illegible] or details. About £5 is allowed to each student by Government and his drawings become the property of the academy. On returning to the school at Vienna these drawings are worked out to a large scale by the students and afterwards traced in lithographic ink by the younger students, and published, each student having a copy. Alternately with the making of these drawings they work out designs of their own, in which [illegible] designs are inspired with the [illegible] they have imbibed in measuring and drawing details of the ancient edifices of the country.

In Stuttgard the instruction is somewhat similar to that at Vienna.

In Germany generally architects and engineers study together in the same schools; in France, architects, painters, and sculptors.

Having in a slight sketch run through the various existing systems of architectural education we must now first, before laying down suggestions for a new scheme, run through them to see the advantages and disadvantages contained in each. The first great failing in England is that the student coming straight from school *is not taught [illegible] that use of the pencil [illegible] which is universally [illegible].* He has little or no knowledge of freehand or geometrical drawing, of physics, mechanics, or of any of the elements of architectural style, and, consequently, he wanders about in too often styleless designs of the architect in whose office he may be placed, and thus acquires by the longest possible process a certain knowledge of a mixture of style and no style, second-hand; his imagination also is not brought into play till his *articles are run out*, and then want of time and absolute lack of training at once curtail his ideas and cramp his imagination. He has picked up a practical idea here and there in the office and numerous details, but he finds himself perfectly unable to group a building of any size. In many cases he has never had an opportunity of visiting or studying any one of the buildings the drawings of which he has been continually at work on, and, therefore, supposing he has been thinking for himself, has never seen the results of his thoughts and inquiries. He has in fact taken from three to five years to learn imperfectly what might have been learnt well in one or two if his mind had been properly trained to receive it and a proper and intelligent course of study pointed out. It is perhaps true that an intelligent student in a good office may learn a great deal by working out practically in the workshop of architecture (as it were) various designs; but also good offices and intelligent students to that degree required are very few and far between, and we are bound here to legislate for the average class.

If we now turn to France, we find that foundation of knowledge [illegible] wanting in England; before the student enters any office his hand is trained to draw freehand and architecturally in the primary drawing schools, and his mind trained by the peculiar instruction there afforded in mathematics and descriptive geometry. He enters the studio and the elements of style are learnt and architectural drawing carried to a higher pitch; in the Ecole des Beaux Arts, wood, iron, and stone construction, with specifications, are worked out, interspersed with original designs. The student works not so much in rivalry with his fellows as *in studio against studio.* Now this rivalry of studio against studio is the greatest feature in French education, and although descriptions of the latter have often been given here in England, this important feature has never been even alluded to. The isolated effort of one individual in rivalry with another may—nay, must—continually fail, because style is not, and never can be, entirely worked out by one man. An original

genius suggests a theory, a second carries it a little further, by numerous others it is taken up, till at last this new idea becomes an established fact. A number of men working in one studio form a school; in order to maintain the prestige of such a school when pitted in friendly rivalry against others, each student in it exerts himself to his utmost, the elder ones give advice and help the younger ones in working out their drawings. The energies of both are brought into play, each learns immensely in a short time, and this unison of feeling, this mutual co-operation, these valuable friendships formed, last through life: here we have the great secret of the success (so far as it goes) of the French school. Where, then, does it fail? It fails in the very important fact that a studio is not a workshop—the designs made are never carried out; all is too theoretical, the construction designs are made in the first year, before the student knows much of architecture. They are copied from others, and got over as soon as possible as a bore, so that, although the student has received the best foundation for a thorough theoretical knowledge of construction, the practical points are soon forgotten. He can project and lay down on paper vaults, bridges, and roofs of any kind, but the economical uses of stone and wood he fails to appreciate; the use of brick or of iron is unknown to him. The student who obtains the Grand Prix de Rome at twenty-five and returns to Paris at twenty-eight years of age, and who is at once named architect of some great public building, has forgotten how a truss is framed, and is absolutely ignorant of the scantlings of timber for any use whatever, still more so the writing of specifications and other practical details, or even the routine of an office. This accounts for the poverty of modern French architecture. It is never constructional, but fritters itself away in meaningless, though sometimes extremely beautiful, detail.

In Berlin this want of practical training is avoided by the student being obliged to study for one year previous to entering the school in a regular office, for the practical training afforded there, and (if he takes any position) for the three years spent as inspector of Government buildings in the school, the student's attention is directed to all the details of design. Besides the composition of buildings he has to work out and copy designs for ceilings, staircases, cornices, &c., to a large scale, from time to time to turn his attention to surveying, supply of water, ventilation, the writing of specifications—in fact, all that is necessary to commence practice with.

Placed, however, by the side of French education it fails in this, that the students all work *in one school, under one set of professors, and the rivalry is between one another* instead of *between studios*. Add to this, that for ever and ever, eternally, they copy the designs of Schinkel, his ceilings, staircases, cornices, &c., which, being all in the coldest and poorest style of Greek architecture, cramp their minds, and they rarely, if ever, seem to emancipate themselves. Now and then a genius like Stüler advances a pace or two further, but throughout Prussia a hard and cold style prevails, which may be partly the consequence of the character of the people, but which must be to a great extent due to the restriction of their studies when young to the works of one of the greatest men Prussia has produced, but whose style is now gone by.

In Vienna the system of study from ancient buildings has only just been commenced, and its result is not yet visible. There is one unfortunate circumstance connected with it, which is that in and near Vienna there is no architecture which is good in epoch, and, as all the ancient churches and buildings belong to the most debased period of Gothic architecture, it will only be the purifying influence which the study of Greek architecture in the school will afford that will prevent the students from copying and designing in a debased style. It cannot, however, be denied that in Vienna are to be found some of the finest modern buildings in Europe. Whether we look at the numerous palaces of the archdukes, at the Exchange, the Arsenal, or new Votive Kirche, we observe an originality of design, based on good models, for which we must look further than the school. We think that much of this is to be referred to the fact that as (in common with all Germans) the Austrians are very fond of travelling, and as the whole of Italy, and till within the last few years the towns of Austrian Italy were especially easy of access to them, that much good has been derived from their studies there, and all those architects who have taken a good position in Vienna have travelled from six months to two years before settling into practice; the more practical training than in France which the student has received in the school giving him a better opportunity of deriving benefit from his travels.

The Ecole Centrale in Paris has not been established long enough to see its results. There is, perhaps, an excess of theoretical subjects, and all is set before the student in too theoretical a manner. Instead of confining the attention of the students more especially to those points with which he would have to grapple in the first ten years of his practice, they enter into abstruse subjects, such as sanitary science, health of towns, political economy, natural history, &c. The chief of the school also, M. Trélat, is an engineer, and, believing that all the finest problems of ancient art have been the result of scientific research alone, his lectures on art and design tend to the development of this belief, and bring about no result. It is also much to be doubted whether design can be taught by theory in a series of lectures at all; and whether, as the conditions of each problem are different, any laws can be laid down for their development beyond those which are afforded by precedent, and precedent or bygone architecture is not admitted into the teaching of this school—a fallacy which the designs at South Kensington show very plainly.*

FONT AT DRYBURGH ABBEY.

THE Abbey of Dryburgh, though less known and less praised than its neighbour of Melrose, is more than equal to it in beauty of situation and severe grace of detail; it lacks, indeed, the elaborate carving and varied tracery of Melrose, but (to the student of architecture) this is counterbalanced by the thoughtfulness of its design, which gives the greatest effect by the use of the most simple means, and also by the symmetry and suggestiveness of its mouldings and details. Like many of the principal Scottish antiquities, it is pretty fully illustrated in Billing's magnificent work on the "Baronial and Ecclesiastical Antiquities of Scotland." From the "Chronicle of "Melrose," we learn that it was founded about the year 1150, during the reign of David I., by Hugh de Morville, Lord of Lauderdale, a favourite of the King, who created him Constable of Scotland. Its site was supposed to have been originally a place for Druidical worship. Edward II., in his retreat from Bannockburn, encamped in the grounds at Dryburgh, and tradition says that the monks jeered at the soldiers of the fugitive army, who, in revenge, set fire to the monastery and burnt it to the ground. 'Robert I. contributed liberally towards its repair, but it has been doubted whether it was ever fully restored to its original magnificence." The last sentence I quote from the guide book, and I think the early character and rich ornamentation of the fragment of the font, which I set down as part of the original work, goes a good way to prove that the present ruin, good as it is, was at its best only a faint reflex of the original building, being, it would seem, the recast of a different and later period, and designed with much more regard to economy than the original monastery. In 1544 the Abbey again suffered from a hostile incursion of English, who, it is said, destroyed it, but I fancy the destruction could only have been partial. It is worth while, however, noting these facts, for usually there is a vague idea that the odium of wrecking Scotland's finest antiquities ought to be laid on the shoulders of Carlyle's hero, John Knox, and the Reformation party.

The fragment on which the present sketch is founded has more delicacy in its design and execution, and approaches more nearly to the ideal of Norman ornament, than anything else I have yet seen. My sketch was taken some years ago hurriedly, and in the twilight, and it is very likely the present illustration does not do justice to the original.

Of the other three sketches on the same page the central one was done in the Hospititum of St. Mary's Abbey, York. The other two are from sketches made at Canterbury Cathedral.

J. M. S.

M. Berryer, the celebrated French advocate, says *La France*, will be interred at Angerville, in a vault constructed after his own designs.

* To be continued.

WORKING MEN'S FREE INSTITUTE, MONMOUTH.

THIS building was opened on Thursday, the 15th of October. It has been built by a charitable lady, Mrs. Matilda Jones, of Ancre-hill, near the town, who has also endowed it for the free use of the working men of Monmouth under the care of trustees *in perpetuo*. The plan is a parallelogram 52ft. 6in. by 32ft. 6in., with a transeptal wing 28ft. by 15ft. on the south side. It has two stories. The ground floor is 12ft. high, comprising a spacious entrance vestibule, and hall, with mosaic floor, from which an inner vestibule is entered through an ornamental glazed wood screen with self-acting folding doors.

From this inner vestibule the following rooms are entered:—The reading and news room, 32ft. by 16ft., which is lighted in front by a coupled window, and in the side by two windows of a similar character; the library, 20ft by 13ft. 6in; committee room, 14ft by 12ft., which can also be entered from the reading room.

From the outer vestibule stone stairs, 6ft. wide, with ornamental balustrade of hammered wrought-iron, lead to the lecture hall, 48ft. by 28ft. and 20ft high. Midway on the south side, and above the doorway, is a pointed arcade of two openings to a gallery over the landing and staircase, which is approached by a circular stairs from a cloak-room forming a mezzanine story on the first landing of stairs. Beneath the mezzanine, and approached by a few steps from the outer vestibule, are a lavatory room, urinals, and watercloset, and on the basement are a boiler room for tea purposes, cellars for coal stores, &c.

The general style of the edifice is of Italian Gothic character. The exterior is constructed with polled red sandstone walls and Bath stone dressings and strings, interspersed with blue forest stone bands; the shafts of the columns of entrance doorway and windows also being of blue forest stone polished.

The noticeable features are the lofty gabled front, 54ft. high, surmounted by a banneret of hammered iron, coloured and gilt with crystal points. In the centre of the gable is the large pointed window of the lecture hall. This window is subarcuated as a triplet on circular columns with foliated capitals, the spandrel being filled in with the arms of the founder, surrounded by diaper and foliations of a conventional character. The entrance doorway, flanked with moulded jambs and circular columns with foliated capitals and moulded bases, is finished above with a bold octagonal balcony carried on massive moulded brackets and corbels with pierced spandrels. The architect was Mr. B. Lawrence, of Newport. The contractors were Mr. C. Lawrence, jun., Mr. George Webb, and Mr. H. Elias. The cast-iron work was supplied by Messrs. Macfarlane, of Glasgow, and the hammered iron work by Cormell, of Cheltenham. The carving is by Mr. J. Willis.

THE NORTHERN ARCHITECTURAL ASSOCIATION.

THE quarterly meeting of the Northern Architectural Association was held on Thursday, the 26th inst., in the keep of the Castle, Newcastle, under the presidency of Mr. J. Watson. It was announced that a sum of £10 had been received from the Architectural Benevolent Society, on behalf of the widow of a deceased member, being the third sum sent for similar purposes. Mr. Henry Leighton was elected a member of the association, the vote by ballot being unanimously in his favour. The minutes of the seventh annual meeting of the Architectural Alliance, at which Mr. Johnson had attended as a delegate, were then taken as read; but as a letter had been received concerning a resolution to the effect "that information should be obtained from the allied societies as to the facilities for architectural education now existing," it was agreed to have a special meeting for the due consideration of the subject. It was suggested, however, as a means for securing greater efficiency in the profession, that architects should refuse to take pupils into their offices who had not previously been twelvemonths in the School of Art. The president elected for the ensuing year was Mr. J. Watson; the vice-president, Mr. R. J. Johnson; the treasurer, Mr. Charlton; the secretary, Mr. Thos Oliver; the hon. solicitor, Mr. G. W. Hodge; while the new committee men were Messrs. Hogg, Fowler, Thompson, Johnstone, and Parnell. Mr. Watson having returned thanks for the honour conferred upon him, the meeting separated.

ARCHITECTURAL THOUGHT AND TASTE.

AS in the world of politics and religion so in art, there are two great parties or currents of thought ever in apparent conflict, though essentially agreeing in the main. It will be found the disagreement consists chiefly in the method of applying and not so much in the great principles themselves. Looking at the practical results of this disagreement, it is a common though mistaken notion that our extended education and our modern facilities and appliances are really detrimental to our social well-being and to our progress in art. Some people point with a mistaken pride to what they term "the good old days," when party and political strife did not run so high, when the national and established religion held supreme and undisputed sway—in a word, to a time when things ran smoother and better with them as a homely and social race. There were fewer feuds between men and manners; the jarrings and discords of a noisy and over-busy age had not broken the quiet of an old *régime*; and there was little or no competition to exert and strain our bodies and brains. A deeper inquiry and consideration will show, however, that such an idea is both inconsistent with progress and obstructive. Thus one party of politicians, religionists, or artists is continually keeping back or hindering the march of improvement, while another party is as zealous in forestalling it. In spite of the most obstructive policy no less than in spite of the most restless advancement mankind will more onwards. An agreement in principles and in the means of applying them is an impossibility in these days, when there is a variety of minds. Conflict must ensue, and the fiercer the conflict the quicker the results which sooner or later become accepted. Existing examples of art—and I wish to confine my readers' attention to the progress of architecture—show that all the contrary grooves of taste and thought are in spite of themselves moving in one direction or in such a modified direction as the force of the most powerful impulse would give. In the case of architectural thought, the movement is in much less distinct and decisive manner than in political and physical science, because, unlike them, the law of cause and effect is not so manifest. People, especially the ordinary educated, are not likely to connect or associate loopholes, machicolations, or a feudal style of building with the feudal or military system of society; nor are they likely to attach any particular significance to light and composite structures in which fenestration and economy of material are notable features.

Comte, in his "Philosophy of the Sciences," shows us a grand law of evolution agreeably to which all changes of humanity, historical and intellectual, have followed, and he logically constructs therefrom a reorganisation of the elements of society by which the intellectual and scientific precede the moral and political. We are now undergoing that process of critical elaboration necessary to the grand recomposition of science, art, and politics, and the final co-ordination or reconciliation of truths. In preceding ages, art, as thought, always showed a predominant spirit. It was generally religious—the theological and metaphysical element preponderated. Now the secular and religious movements are striving for mastery or reconciliation; hence it is we see the antagonism existing between styles, we have our houses and townhalls partaking of the same character as our churches. So long as the current of thought ran in particular grooves the slightest interruption was fatal to art, or so impeded its progress that it often became stagnant. Thus it was with the great periods of Greek and Roman art and its offshoots, especially the period of mediæval excellence. The current of thought and art had not been interrupted, for religion and art were intimately associated and continued to be so till the dawn of the fifteenth century. At that time a separation commenced; the religious and secular movements became distinct; religion and art, hitherto allied, henceforward became new and disconnected powers. Dependent on itself, art had now to find a new basis—some more scientific method, and until it could find this it had to borrow or confine. The art renaissance of all countries indicates this moral divergence and change.

In this nineteenth century we find art studied for its own sake; borrowing and appropriating, possessing little of its former spirit and unity, it will nevertheless ultimately take its place as a science co-ordinated in the grand scheme of human ideas, yet to be organised out of the apparent chaos and conflict of our civilisation. It is this grand correlation of ideas in prospect that lends a spirit and aim to our study of architecture as to every other branch of thought and speculative inquiry, and if we will but try to eliminate the sentimental and antiquated from the logical and modern, and infuse the spirit of modern thought more into our designs, despite the ultra-copyists of every school, the quicker will be the realisation of an art at once homogeneous, national, and progressive. In another paper I hope to point out more practically the false sentiments and crudities that have crept into our architecture.

G. HUSKISSON GUILLAUME.

THE WORKING CLASSES AND THE PATENT LAWS.

ON Monday evening a meeting of the Inventors' Institute, under the presidency of Lord Richard Grosvenor, M.P. (president), was held at the offices of the institute, St. Martin's-place, Trafalgar-square, when the patent laws, as affecting the interests of the working classes, were discussed. Members of the invention right committee, consisting of delegates from numerous industrial associations, attended to explain proposed reforms in the patent laws, and to confer with the meeting thereon. The noble chairman, referring to the patent laws, said there existed among all classes, and especially among working men, a strong feeling that the patent laws needed simplification and modification. In the new parliament there could be no doubt that the legislature would interest itself much more deeply in social questions than heretofore. Education would no doubt form a subject of much discussion in the new parliament, and education was so closely allied to the objects of the institute that such discussion must affect the present patent laws. Mr. Hume Williams addressed the meeting, and having paid a high tribute to the memory of their late president, Sir David Brewster, spoke of the expediency and justice of the patent laws, and said that even in these days of free trade there was little ground for apprehending that capital and intellect would be placed in antagonism by any attempt to abolish the protection which satisfied the just requirements of each. In this age of progress it became a matter of the utmost importance that the inventive genius of the country should be fostered and protected. To new inventions in machinery they should look for additional progress; but still not neglect the old ones. Agreed upon the broad principle of protection to invention, it appeared to the council of the institute that the education of artisans in mechanical knowledge and their guidance in scientific study were matters not unworthy their attention, and accordingly steps had been taken to advance those objects. He concluded by stating that it was intended to inaugurate a benevolent fund for men of science, to which they could appeal in time of need, not as a matter of charity, but of right. Mr. Savage said he had been all his life in contact with intelligent working men, and from his knowledge of the manner in which the patent laws worked, he could say that their action was tantamount to putting 50 per cent. of the intellectual power of the country into the grave. Some of the best inventions had never been patented because of the expense. The steel pen had never been patented, on that account. Since 1861, very few new inventions had been exhibited lest they might be copied. It was said that the inventor of the sewing machine had derived no benefit from his invention in this country because he was too poor to take out a patent. Captain Selwyn, R.N., thought that a working man's patent should be solid and reliable, because the present patent law was nothing but a permission to go to law. They must first of all have cheap protective law; next, such an investigation as would assure the poor man he was not paying for a sham; and thirdly, such publicity and encouragement as could only be given by an institute. Hitherto invention had been pulling one way and manufacturers another, but a better time for both parties was arriving. Mr. Patterson asked why a man should pay a tax for having his brain property protected. Why should a working man be called on to pay anything beyond a registration fee? It was not right to complain that working men did not move when they were actually taxed for doing so. Mr. Siemens thought that where there was an allegation of an infringement of a patent commissioners should be appointed, who, without stopping a manufacturer's business, could ascertain the truth of the allegation. Mr. Webster believed that an invention should be as much protected as property in matter. The state of the present patent laws was a disgrace to a civilised country. After further discussion a vote of thanks to the chairman closed the sitting.

CLOCKS, AND THE STRUCTURAL ARRANGEMENTS MADE FOR THEIR DISPLAY AND PRESERVATION.*

THEORETICALLY, no doubt, the weights of the clock, and consequently their casing, should run plumb down from the barrels to which their descent supplies motion, but this would sacrifice too much room beneath, and generally be so inconvenient that by common consent of architects and clockmakers it should be considered as the usual thing to collect the weights and take them down in the nearest convenient angle of the structure in which the clock was to be placed. If this was not attended to in the first instance by the clockmaker, he was nearly certain to be called upon to make alterations which might lead to increased expense and possibly to discord. Where the architecture of a lofty clock tower at all lent itself to such a feature, much trouble and ultimate expense would be saved, and the appearance of the clock dial much better maintained than was likely to be the case where such a feature was omitted, if the architect should provide a balcony or projecting gallery at such a distance below the dial as to admit of its being easily reached by short ladders, the balcony or gallery being of course accessible by a door from the interior of the tower. Such a balcony might of course be made useful as masking reflectors and gas jets throwing light upon the sound clock faces where dials were required to be illuminated which it was not convenient to make transparent. They would also be serviceable as facilitating the lowering down of any portion of the clock machinery which might require to be taken out for repair or replacement. Their main use would, however, of course be to furnish ready opportunities for cleansing the hands and dial faces, for freeing the main arbor bearing the hands from dust and dirt, and for regilding the hands or figures. To perform any of these operations at the top of a lofty tower unprovided with such means of external access would involve an outlay for scaffolding and a risk of men's lives of the most serious kind. With respect to transparent dials illuminated by gaslights burning between the clock dial and the works, the architect should take care that two provisions were made by the clockmaker—one that a screen (4½in. hollow brickwork in cement, covered on the dial side with white tiles, was the best) should be fixed at such a distance in the rear of the clock face as should allow of a man getting into the chamber for the purpose of shutting off and adjusting the gas burners, &c., the object of the screen being to shut off the products of combustion from the going parts of the clock; and the other that any counterweights to the clock hands which might be requisite to neutralise their leverage should be fixed on the outside and not inside of the dials. If this was neglected Mr. Denison stated that very puzzling shadows would be thrown on the clock face. For the purpose of ventilating this chamber and the clock separately, the architect should provide four apertures through his walls, two at the level of the clock floor and two at the ceiling level of the clock chamber. If he should provide more air passage than was absolutely necessary it was easy to shut off any portion of it, but if he should provide little or none it would be difficult and costly to obtain a sufficiency after the building

* Concluded from page 305.

might have been completed. Moreover, if the mode of provision was left to a clockmaker and a clock committee after the architect's connection with the structure might have ceased, the chances were ten to one that the apertures were made in just the way and place in which the architect would prefer that they should not be made. Such being some of the conclusions to which Mr. Wyatt's studies of the subject had led him, he thought it well to supplement them by giving a copy of the following interesting letter which had been written to him by Messrs. Moore, of Clerkenwell, whom he had consulted upon the matter :—

SIR,—Upon looking over the paper you gave me in reference to particulars you required concerning clocks, &c., of various sizes I find I should be at a loss to supply the information you wish, as it would take up much time to give anything like an accurate statement. But I would submit that the size of the dial or dials determined upon when making the drawings of any particular building would be sufficient to guide any architect as to the space required for the works of the clock, and should say no space less than 3ft square by 4ft. high (for the smallest clock) would be available for a man to wind the clock, &c. But in many cases it would be more convenient to place the clock movement below, and lead up to the dials with rodding and angular wheels, and as it is very unusual to have a turret clock without striking the hours the space should be allowed the same. It is desirable to have the clock as near the dials as possible, and if convenient the bell or bells should be placed above the clock, with a lead flat to prevent the weather getting into the clock chamber. The bells should be, where practicable, as open as possible; any wood or slate louvres tend materially to obstruct the sound; if louvres are used at all they should be glass. The bells in church towers are hung lower than the weather boarding, and as the clock strikes the bell when at rest the sound is much obstructed. Of course when the bells are ringing the mouth is upwards and level with the openings, and the full sound escapes. When illuminated dials are to be used openings the full size of the dials must be made, and if convenient splayed off to the inside. With proper management a 6ft. dial could be well illuminated with two ordinary burners. A good proportion for size of dials (to be thoroughly useful) would be 1ft. for every 10ft. above 0ft. high. Below that height 4ft dials would do very well. Where 4ft. dials are used the clock floor should not be less than 6ft. below the centre of the dials (it might be more); but if one, two, or three dials are used the floor might be 4ft. 6in., or 5ft. below the centre. In large clocks a 14ft pendulum should be provided for if practicable, and in all cases the pendulum should be as long as circumstances would allow of. In some church towers clocks are fitted up in the bell chambers and thus much exposed. They should always be placed in a chamber below, and, if necessary, lead up to the dials, as before described. Arrangements should be made to get the greatest fall possible for the weights, as upon this the performance of the clock much depends. It is not absolutely necessary that the weights should drop immediately under the clock (although if convenient it is best), since they can be carried off by pulleys to any convenient place where the fall could be obtained. At all times when it is decided to have a clock it would be well to consult with the maker selected to supply it, in order that everything may be properly arranged before commencing the building. We take this opportunity of naming that it has often come under our notice in clock turrets that no provision has been made for the escape of the sound of the bell, and this has caused much inconvenience and annoyance to all concerned. In some instances a bell cote has been added outside, which has had the desired effect of getting the full sound out of the bell. We have lately put up a set of chimes with fifteen bells on the top of the tower of Sudeley Castle, Gloucestershire, and the tunes played upon these bells are distinctly heard for two miles, although the fifteen bells together only weigh 5 cwt., while at the village church there is a very large peal of bells, playing tunes, and the same are not heard half a mile off. This difference in sound is almost wholly attributable to their position, the bells of our clock being exposed to the open air. We have merely a glass roof to cover the works. The bells are in no way affected by exposure to the weather. . . . I remain, &c., for self and partner, JOSIAH MOORE.

M. Digby Wyatt, Esq., F.S.A., &c.

P.S.—Clocks are sometimes constructed in horizontal frames, but in many cases this is objectionable in consequence of their taking up much greater space. They are more convenient in upright frames.—J.M.

The following particulars were those which should be furnished to a clockmaker, as without them, at least, he could not furnish any estimate of cost—viz, size of dials and how many, weight of bell the clock was to strike upon. If the weight of the bell was not known, by measuring it across the lip or mouth, and comparing it with the following, the weight would be ascertained :—

Diameter of Bell. ft. in.	Weight. cwt. qr. lb.	Diameter of Bell. ft. in.	Weight. cwt. qr. lb.
1 0	0 1 12	2 4	5 0 0
1 1	0 1 12	2 5	5 2 0
1 2	0 2 6	2 6	6 0 0
1 3	0 2 16	2 7	6 2 0
1 4	0 3 0	2 8	7 0 0
1 5	1 0 0	2 9	7 2 0
1 6	1 1 0	2 10	8 0 0
1 7	1 2 0	2 11	8 2 0
1 8	1 3 0	3 0	9 0 0
1 9	2 0 0	3 2	10 0 0
1 10	2 1 0	3 4	11 0 0
1 11	2 2 0	3 6	12 0 0
2 0	3 0 0	3 7	13 to 14 0 0
2 1	3 2 0	3 9	14 to 16 0 0
2 2	4 0 0	3 10	17 to 18 0 0
2 3	4 2 0	4 0	20 0 0

The author had not entered into any detail upon the subject of clock bells in this paper, because the matter was so fully gone into in the "Transactions" of the Royal Institute of British Architects; but there remained two points of importance which he should notice before concluding—viz., the construction of a rule, firstly, for the size of the clock chamber; and, secondly, for the position of the level of the clock floors or beams below the centre of the hands. With respect to the first, he thought, from observations he had made, that the diameter of the dial *plus* 2ft. might be adopted as the suitable gauge of any clock chamber, both for width, height, and length, including space for winding; and with respect to the second, that if the floor of the clock chamber was placed the same number of feet below the centre of the dial the rodding for working the hands would be sufficient without waste. The same sliding scale would be sufficient for the arc of vibration of the pendulum, whatever its length might be. Upon these points, as he had only endeavoured to construct an empirical rule for his own observation, he should be glad to be corrected. Nor was this the only point upon which he might have to ask for indulgent criticism and correction. To a considerable extent in this paper he had been groping his way without much light from others, and he might naturally have knocked his head against many blunders. His object would have been answered if he might hereafter spare the heads of his hearers from some of the many bumps he might have himself incurred.

A short discussion ensued, in the course of which Mr. Redgrave proposed and Mr. Phené Spiers seconded a vote of thanks to Mr. Wyatt for his valuable paper. Mr. Wyatt briefly responded, and the proceedings terminated.

THE INSTITUTION OF CIVIL ENGINEERS.

THE first meeting of the session 1868-9 was held on Tuesday, November 17, Charles Hutton Gregory, Esq., President, in the chair, in the new building, erected during the recess, and upon the completion of which according to the promise made by the council the president congratulated the members; taking occasion to remark that the council had placed upon their private minutes a unanimous vote of thanks to the architect, Mr. T. H. Wyatt. The president observed that the contractors, Messrs. Holland and Hannen, were also entitled to commendation for the manner in which they had carried out the works within the time specified in the contract—a result to which the personal care of the secretaries had largely contributed.

The paper read was "On Lighthouse Apparatus and Lanterns," by Mr. David M. Henderson, Assoc. Inst. C.E. It was stated that this communication might be regarded as a sequel to the paper "On the Optical Apparatus of Lighthouses," by Mr. James T. Chance M.A., Assoc. Inst. C.E., read during the session 1866-7.

The glass used in lighthouse apparatus was nearly all made at Saint-Gobain or Birmingham, and was of the kind known by the name of crown glass. Different mixtures had been employed for the purpose; but M. Reynaud, the director of the French lighthouse service, now gave the composition as—

Silica	72·1
Soda	12·2
Lime	15·7
Alumina and Oxide of iron	traces.
	100.0

At Birmingham various mixtures had been tried, of which several examples were given, the following being about an average :—

	cwt.	qrs.	lbs.
French sand	5	0	0
Carbonate of soda	1	3	7
Lime	0	2	7
Nitrate of soda	0	1	0
Arsenic...	0	0	3

English glass was supposed to be of the refractive index of 1·51. That produced at Saint-Gobain had formerly an index of refraction as low as 1·50, but now it was 1·54, and frequent experiments were made to ascertain that the standard was maintained.

The furnace for melting glass was generally rectangular in plan, and was constructed of the most refractory materials; and the sides were arranged so as to allow of the easy withdrawal of the pots. Six, and sometimes eight, pots were placed in the furnace, arranged in pairs with a firegrate at each end. The flame filled the whole interior of the furnace, and, after circulating round the pots, which were covered to prevent the colour of the glass being injured by dust or impurities from the coal, found its exit by flues. Great care was necessary in the preparation of the pots, which were made of about one-half new fire-clay, and one-half old potsherds finely ground. The length of time a pot would last depended upon (1) the quality of its manufacture; (2) its being slowly and thoroughly dried—a process occupying about six months; and (3) the care bestowed upon it in the furnace, and whilst withdrawn for casting. The average number of castings from each pot was about twenty; and the time the pot was out of the furnace at each casting was about three minutes. It was mentioned that Mr. Siemens' regenerative furnaces were now in use for the manufacture of lighthouse glass with perfect success. When the metal was ready for casting, each pot was lifted from its seat, withdrawn from the furnace, and carried to the foot of a crane, the lifting chain of which had attached to its end a clip to embrace the pot. A mouth-piece of wrought iron was fitted to the pot before casting, to facilitate the pouring, and the workmen tipped over the pot by means of long handles.

The casting table was circular, and was mounted on a frame, so that by means of a handle it could be turned round, and each part of its outer circumference brought consecutively under the pot of molten metal. The moulds into which the glass was to be cast were arranged around the outside of this table, and were caused to revolve slowly under the continuous stream of liquid glass flowing from the melting pot, so that each mould was filled in succession, thereby enabling the immediate return of the empty pot to the furnace. The moulds were of cast iron, of a uniform thickness of ¾in., and were supported on feet cast on, the size being such as to allow ¼in. thickness of glass all round for the grinding process. The small lens-rings and prisms were cast in one piece but the larger ones were cast in segments. The large belts, or central lenses for fixed lights, were generally cast flat, and were afterwards bent on a saddle to the required curve in a kiln.

Sand, emery, rouge, and water were the four necessaries for glass grinding and polishing. The sand had to be applied, with abundance of water, until it lost its cutting qualities. The emery, after being ground to a fine powder, was agitated in water, and the mixture was passed through a series of vats or tubs, so that the emery was divided into as many qualities as there were tubs, the coarsest being deposited in the first tub, the finest in that furthest from the supply. The rouge, which was an oxide of iron, was prepared from the sulphate, and was separated into qualities by means of water tubs, as in the case of the emery. The glass of optical apparatus was ground on horizontal circular tables, securely fastened to the tops of wrought iron vertical spindles, which received motion from the main shafting in various ways. The surfaces of these tables were divided out, like the face plate of a lathe, to receive the different sizes of "carriers," or supports of cast iron, which were bolted to them, and were arranged to hold the lenses or prisms to be ground. Plaster of Paris was then laid on the "carriers" in bands, the bands being reduced to the exact size by turning the table round under a gauge secured to the framing of the machine. The glass was laid on these strips, and was secured in place by means of pitch, care being taken in the larger sizes which were ground in segments, to place a thickness of pitch between each joint, so that glass did not touch glass. A detailed account was given of the method of grinding a belt or central lens of a fixed light, and also of grinding a bull's-eye or central piece of an annular lens.

The various sizes of catadioptric lights were next given in detail; and it was stated that, in order to produce a distinction between different lights, some were fixed and others revolving, while there were many combinations of the two classes. Again, there were modifications to render fixed lights intermittent, and colours had also been employed to both fixed and revolving lights.

In reference to the method of mounting the lenses and prisms, it was remarked that sea-lights, on account of their size and weight, were necessarily divided into several portions. The section of the apparatus, consisting of lower prisms, lenses, and upper prisms, gave a convenient division into three tiers, each of which was sub-divided into panels of a convenient size. In a first-order

fixed light, the circumference was divided into eight panels of 45 deg. each, which were made of gun-metal racks, or side-pieces, formed to receive the lenses or prisms, these side pieces being connected together by gun-metal segments of rings at the top and bottom The author then proceeded to describe minutely (1) one segment of a first-order light, in which all the joints of the panels were vertically over each other; (2) an arrangement with inclined lens-panels, the upper prism-panels being so placed that their joints did not come vertically over those of the lower prism-panels; (3) a first-order apparatus, where the upper and lower prisms were fixed; (4) an eight-sided revolving light, collecting the whole light into eight beams of parallel rays; and (5) a first-order apparatus, commonly called a "Fixed Light varied by short Eclipses," a title which did not convey the actual effect, as the fixed light was followed by an eclipse, then a flash, and next an eclipse, the same phases being continually repeated.

The construction of the panels was referred to in detail; and it was observed that, when the fitting was finished, the panels were taken to the erecting shed, where they were erected on their pedestals, or on, what was more convenient, a revolving table, specially constructed so that each panel, or part of a panel, could be brought in succession opposite the erecting post. The prisms were passed into their places, one end covering plate of the panel to be set being removed, and wooden wedges were used to support the glass and enable it to be accurately adjusted in its position by means of internal observation, as explained by Mr. Chance in his paper. When the prisms were adjusted, plaster of Paris was applied at all the corners to retain the prisms in their correct position, and when fairly set, the wedges were removed and the remaining spaces filled in with best red lead putty.

The arrangement of panels generally adopted was that of placing one panel over the other, so that the joints should be vertically over each other. It had in its favour simplicity, a minimum loss of light, a minimum cost, and strong, convenient-shaped panels. These advantages had been considered of such importance that in France this method was still adhered to, and all the lanterns were constructed with vertical standards placed in front of the obscuration caused by the sides of the panels. This plan, however, rendered as many points, or rather small arcs, on the sea as there were standards in the lantern, to be illuminated with a considerably weaker light. The late Mr. Alan Stevenson was the first to introduce inclined lens-panels, with a view to equalise the distribution of light on the sea, but he was, no doubt, well aware that the total loss of light would be increased. Inclined standards had been adopted in several instances, but without any alteration in the optical apparatus. The horizontal divergence, resulting from the size of the burner in a particular case alluded to, might be taken at 6 deg, and the standard was inclined over an angle of 7½ deg in plan, so that when an observer was placed in front of the standard, it nearly stopped off the light from him throughout its entire height, commencing on one edge of the flame and finishing on the other, thus obstructing much light which had successfully passed through the apparatus. The lantern of Mr. Jas. N. Douglass, M. Inst. C.E., the engineer to the Trinity House, was designed to render impossible a correspondence, or optical coincidence, between the framing of the apparatus and that of the lantern. In the author's opinion, this lantern was expensive, from the amount of workmanship of a costly class, and from the glass cut to waste.

An arrangement had been designed by the author, with a view to obviate the objections to previous methods. The first consideration was the optical apparatus, and it was apparent that a minimum amount of light was stopped by vertical panels, and that it was possible to divide the previous large obscurations into a greater number of smaller ones, thus equalising the light without increasing the total obscuration. By excentreing or placing the various tiers of panels so that their joints did not come vertically over each other, each previous obscuration was divided into three. The amount of excentreing necessary depended upon the size of the flame, so as to enable one obscuration to be completely passed before entering upon another. In a first order, for example, the panels were 45 deg. each; and, as there was an intermediate rack in the prism-panels, there was a space of 22½ deg. between each obscuration. Each large obscuration could be divided into three small ones, which, if placed at intervals of 7½ deg., would never allow more than one obscuration to be visible at a time. The next consideration was the lantern, which when arranged with excentred panels, was rendered less rigid, owing to its weight not being transmitted continuously downwards, as was the case with vertical continuous standards. This want of rigidity would be objectionable in a light illuminating the whole horizon, but in those illuminating from 180 deg. to 270 deg. (which were by far the most common) the dark arc could be filled in with solid iron plates, by which any amount of rigidity could be obtained. By the substitution of triangular frames in the central tier, it was still possible to retain the upper and lower panels excentred, and to render the framing perfectly rigid, in fact more so than with the vertical continuous bars of the old lanterns.

A detailed description was then given (1) of a first-order lantern with inclined standards, (2) of the lantern to which the French engineers adhered for all apparatus burning oil, and (3) of the lantern arranged by the author to ensure the most uniform distribution of light.

The three principal varieties of lamps in use for sea lights were the mechanical, the high reservoir, and the pressure. The mechanical were the most general, being used in Scotland, France, and many foreign countries. The oil was forced over the burner by pumps, which were worked by clockwork placed underneath and driven by a weight. One of the best high reservoir lamps was that designed by Captain Nisbet, of the Trinity House, and which had been applied to several English lighthouses. Lamps of this class were not, however, applicable to revolving lights, or those illuminating all the horizon, on account of the obstruction of light that would be caused by the reservoir. The pressure lamp of M. Degrand, of Paris, was next noticed. In it the oil was forced over the burner by means of a weight pressing directly on the surface of the oil. It was found that the large space between the piston and the cylinder in this lamp rendered the leather packing liable to turn over when the oil got heated, and softened the leather; added to this, there was no provision for varying the weights on the piston. To meet these objections, M. Masselin designed a lamp with external weights which gave excellent results, and had the advantage, not possessed by the high reservoir lamps, of being equally well adapted for fixed and revolving lights, whether the whole horizon was illuminated or not. This lamp was minutely described; and in the next section of the paper an account was given of a first-order clockwork, consisting of two trains of wheels, one for driving the apparatus, and the other for driving a fly-wheel with adjustable vanes for regulating the speed.

In conclusion, the means adopted for lighting the entrance to Odessa harbour were described. At the extremity of one breakwater a tower was built, to contain a fourth-order optical apparatus fixed for 270 deg, with a metallic reflector for the remaining 90 deg. At the extremity of the other breakwater a beacon was erected, but it was required that a light should be shown without there being a lamp, or any metallic reflector, at that place. Accordingly a sixth-order holophote was placed in the tower, to collect all the light from its lamp into one beam of parallel rays, which was thrown across the entrance to the harbour to illuminate the beacon, producing thus what was called an apparent light. On account of the distance of the beacon from the holophote, 300ft., much light was lost, and the divergence of the beacon was small, but ample for what was required, as it was placed low, and a range of only about 1 mile was required.

The communication was accompanied by fifty-six large diagrams, and by six sheets of carefully executed drawings to a reduced scale.

ARCHITECTURAL ASSOCIATION.

At the meeting on Friday evening last, Mr. Lacy W. Ridge, A.R.I.B.A., vice-president, in the chair, the following gentlemen were elected members.—Messrs. T. A. Longstreet, James Kennedy, William H. Johnson, Montague Hepworth, Arthur Ashpitel, Arthur Warner, George Heighton, Ernest C. White, Herbert Payne, Thomas Batterby, Matthew Henry Hadland, William Frame, J. Arthur Reeve, J. H. Bryan, George Currier, T. A. Tregilla, J. H. Cundall, and C. S. Webber. A vote of thanks was then passed to the architects of Her Majesty's Theatre for the facilities afforded by them to enable the members of the Association to visit the works, after which Mr. J. Douglass Mathews announced that an early opportunity would be afforded the members of visiting the new Gaiety Theatre in the Strand. The remainder of the evening was occupied in reading and discussing the annual reports.

The report of the committee of the Association was first read by Mr. Quilter. It appears that the roll book now contains 466 names of members—for the most part those who are not far advanced in the profession. While every feature of the Association was in a satisfactory condition, the report expressed a hope that the present session would see an augmentation of the number of members taking part in the discussions, which was at present very small. The library, which is still the only architectural lending library, has received so many additions during the past session that it has doubled its number of volumes. The "Association Sketch Book" has completed its first volume. The various prizes offered during the past session have been competed for by more members than usual. More extensive accommodation was being provided at Conduit street for the increasing wants of the Association.

The balance sheet, read by Mr. J. Douglass Mathews, showed an expenditure of £239 17s. 7d. against an income of £331 15s., leaving £91 17s. 5d. in the treasurer's hands. The association was, moreover, not a halfpenny in debt.

The librarian's report showed that whereas the number of readers in session 1866-7 was only 269, the number last session was 423. Contributions have been made by Mr. Beresford-Hope and other donors. The librarian's accounts show a balance in hand of £35, which will be expended in new books.

The report of the Class of Design showed that the attendances and sketches were greatly in excess of those last session. The total number of attendances was 323, and of sketches 170.

The second annual report of the Class of Construction showed a great increase of members, attributable to the practical method of imparting instruction. The class now musters more than thirty members, and the average attendance is eighteen.

Mr. C. H. F. Lewes read the report of the Figure Drawing Class, which is still conducted at the West London School of Art. The number of members is thirty-three, of which number five are not members of the Association. The course of instruction is left almost entirely to the student, who is at liberty to study from plaster casts, anatomical models, or from the living subject. Some discussion ensued on this report, Messrs. T. Roger Smith, Tarver, R. P. Spiers, G. R. Redgrave and others, offering various suggestions as to the future of the class. It was suggested that as the Association was now in a flourishing condition the class should be divided and one division held at stated intervals in the new rooms of the Association in Conduit street. It was also suggested that one division of the class should be for mere elementary instruction, so that the junior members of the Association would be able to join it. Another suggestion made was that paid tutors should be employed, and it was further suggested that the Association should expend a limited sum in the purchase of casts to be placed in the new rooms for purposes of study. In reply to all these suggestions, Mr. Douglass Mathews and the chairman said that when the new rooms were finished the class would doubtless be accommodated, as would also a class for freehand drawing. Nothing had been hitherto paid for tuition, but it was extremely probable that the custom would be departed from in more than one instance before very long.

The report of the Water Colour Class was read by Mr. Florence. This class was established in the spring of 1866, Mr. Aaron Penley being appointed tutor. The number of members was eighteen.

The second annual report of the Sketch Book Club showed that the number of subscribers was 117. Since the commencement of the second volume a vast improvement has taken place in the sketches and lithography. The committee for this year have offered a prize for a new title-page. Non-members are now eligible to become subscribers on payment of an extra half-guinea.

Mr. T. Roger Smith then read the report of the delegates from the Association to the annual meeting of the Architectural Alliance, at which a

deputation from the General Builders' Association had also attended. The officers of the Alliance were appointed a sub-committee to make arrangements for the representation of that body at any conference that might be held on points affecting building contracts. The report of the Alliance, which was distributed in the room, has already been referred to in the BUILDING NEWS.

Mr. R. Phené Spiers then read the report of the delegates from the Association to the Alliance on the subject of architectural education, the first portion of which will be found on another page.

Some discussion ensued, in which Messrs. T. Roger Smith, Blashill, J. Douglass Mathews, and the chairman took part, and the consideration of the report was adjourned.

ASSOCIATED ARTS' INSTITUTE.

AT the meeting of this Institute on Saturday evening last, Mr. R. Phené Spiers, vice president, in the chair, Mr. Charles Henman, jun., architect, was duly elected a member. A discussion then took place on the question, "Does the literature of a nation to any great extent influence its art?"

Mr. A. H. WALL opened in the affirmative, instancing Greece, which as it progressed in literature progressed in art. Art and literature progressed side by side and in the same ratio to each other. In support of the theory that art influences and is influenced by literature the speaker adduced an argument from the fact that literary men and artists understand each other better than most classes. Literature had a power of educating the masses with respect to works of art, and if only so regarded it would be felt to exercise great influence in the art progress of a nation.

Mr. LEMON H. MICHAEL, taking the negative side, maintained that art had much more influenced literature than literature art. Art was the motive power. To a certain extent literature did influence art, but it was the literature of bygone ages that did so. In the time of the Greeks literature did not reach the masses. It was the artistic and not the literary faculty that was dominant in Greece. There literature was more a reflex of art than art was of literature. In the time of our own Elizabeth English literature was perhaps at its highest, but the arts, especially architecture, were at a very low ebb. Again, in the time of Queen Anne, when we had one of the finest schools of writers ever produced, the remains of a few painters would include all the fine art of the period. Ornamental art had chiefly been produced by nations who had had no great literature at all. It was only in comparatively late times that literature had come within the reach of the masses. In mediæval times, when literature was confined to a small number, the artistic feeling was at its highest.

Mr. CRAVEN said that painting, like literature, might be divided into poetry and prose, and these two divisions could be sub-divided. The Classical revival was simultaneous both in literature and art.

Mr. G. R. REDGRAVE was of opinion that the literature which directed attention to art was a literature which was constantly landing works which were not worthy, and trying to bring forward cliques and coteries of men. The Italian artists had no literature to bring them forth. If the education of the public mind were the good that literature was doing artists, literature was not influencing art, although it might be educating the public into true views of art.

Mr. DAY was of opinion that the literature of a nation did very materially influence its art, and in two ways, by art literature proper and literature generally. All art criticism was not puffing. To maintain that Ruskin's works had not had an influence on the art of the present day was to ignore a very great fact.

Mr. RANKING observed that eastern nations which had excelled in art had also excelled in literature. Such were the Chinese and Persians.

Mr. ALDRIDGE said that the influence of literature upon art was a very bad one. The visible influence of literature in a picture at once destroyed the effect of pure art.

The CHAIRMAN said that the revival of Renaissance art in England was dependent almost entirely on literature. Speaking as an architect of Horace Walpole's revival of Gothic, he thought it was likely that buildings influenced Walpole more than literature. All the explanations in the world would never tell one what style of architecture or form of architecture was. It was impossible to describe a good building. If a good description of a building could be given, that building was not worth anything. The subtleties of good architecture were so intricate that they could not be described in words. Pugin's writings had had a great influence, but *he* was, however, influenced by buildings and not by literature. Ruskin almost always chose the very worst periods of Gothic architecture to hold up to admiration. There were few persons of the present day who would say that Ruskin's views upon architecture were at all to be followed or agreed with.

Mr. WALL briefly replied on the whole debate, affirming that literature and art were so intimately intertwined that it was impossible to say where one began and the other ended. Before the time of the printing press the traditional and monumental literature handed down from generation to generation exercised great influence. The prosperity of literature and the decadence of art in Elizabeth's time were attributable to the fact that the one was encouraged and the other not.

The voting then took place on the sketches exhibited (subjects: "The Tempest, Act. 1," and "A meeting"). One by Miss Thornycroft on the latter subject was selected as being most worthy of being photographed. The proceedings then terminated.

PROPOSED NEW RAILWAYS IN THE METROPOLIS.

IN addition to the proposal to connect the fish market at Billingsgate with the great trunk lines, as described in last week's BUILDING NEWS, another and a revived scheme is for a railway (for a greater part of the distance underground) from the Marble Arch to the City. The City terminus will be near the Peel statue, at the western end of Cheapside. In its course the line will pass through or under the following roads and streets:—Uxbridge-road, Bayswater-road, Oxford-street, Duke-street, Regent-street, New Oxford-street, Holborn, Holborn Viaduct, Farringdon-road, Skinner-street, and Newgate street. This line, if constructed, would be a great relief to the great highway between the City and West-end.

The promoters of the Port of London and Billingsgate Railway also propose a short line from Smithfield to Blackfriars, on a lower level than the branch to the Chatham and Dover line, to connect the Metropolitan Railway at Farringdon-street with the district line on the Embankment, thus bisecting the inner circle of metropolitan railways.

The bill for constructing a railway from Islington-green to the City, which was thrown out last year, is to be again brought forward in the coming session. The line proposed will form a continuous bridge or viaduct, and will be constructed to a gauge of 3ft. The safety and economy of a gauge less than ordinarily adopted have been already proved by the experience of years both at home and abroad. The Festiniog Railway (gauge only 2ft.) has during the year carried 120,000 passengers and 125,000 tons of goods, and there has not been a single accident during the four years since locomotive power has been placed on the line. It has been most favourably reported on by Captain Tyler, R.E., the Government Inspector. It is proposed to have an intermediate station in the City-road, near the "Eagle." The line of route marked out is parallel to Packington-street, Shepherdess-walk, and Bunhill-row, that is to say, parallel to the new direct route to the City which was partially opened a few weeks ago. It is estimated that 40,000 persons take this route daily, and as the third class fare proposed for the journey will be one penny, a large traffic may reasonably be anticipated. The estimated cost is £800,000, and the time required for the construction of the line is twelve months.

ARCHÆOLOGY.

DURING the last few weeks several specimens of Roman pottery have been found in dredging on the Whitstable oyster grounds. They are similar to the numerous other specimens which have at various times been discovered there, and which consist of small bowls and cups, circular dishes, and flat stands surrounded by a rim like a modern cheese dish. They are all made of the red glazed ware known as "Samian." All the specimens are plain, and were evidently made by being turned on a potter's wheel. This is somewhat remarkable, as, while much of the best Samian ware was so made, there was a mode of manufacture in which a mould was used, and the articles were thus adorned with figures in relief. The period to which this kind of pottery belongs is from the first century B.C. to about the third century A.D. It was undoubtedly imported, and must not be confounded with the Romano-British pottery, which began to be made about the third century, and of which there was an important manufacture at Upchurch, near Sheerness.

Building Intelligence.

CHURCHES AND CHAPELS.

On the 13th ult., the parish church of St. Mary, Etton, Yorkshire, was reopened after restoration. The church is of very early date, the tower and north side of the nave being supposed to have been built about 1100—1150. The chancel was rebuilt about 25 years ago in a debased style, partly Norman in character. The tower has now been thrown open to the church, open pews have replaced the old square boxes, and a new roof placed on the tower and nave. The whole of the work has been designed and executed by Messrs. Simpson and Malone, of Hull.

The new Presbyterian Church of St. Paul Montreal, in the dominion of Canada, was dedicated on the 27th of Sept. last. It is in the Early English style, and is built of blue Montreal limestone, with facings of light Ohio sandstone. The plan consists of nave, transepts, and apsidal recess for organ and choir. The length is 140ft., breadth at transepts 95ft., and at nave 60ft. It seats 1,000 persons, at a cost of about £12,500. Mr. Frederick Lawford, a pupil of the late Sir Charles Barry, was the architect.

A new English Presbyterian Church has been opened at Birkenhead. The style is Late Geometric Gothic. The principal elevation is entirely of the stone of the neighbourhood, with a little red stone in bands and arches introduced to give effect. The contract has been carried out by Messrs. R. Anderson and Sons, contractors, Slater street, under the superintendence of Mr. James N. Crofts, architect, of Liverpool. Mr. Turnbull was the clerk of works. The site is the gift of John Laird, Esq., M.P., and the cost of the building about £2,500.

On Tuesday, November 24, the foundation stone of a new Methodist Chapel and schools was laid at Cullercoats. The style is Gothic, and the building will seat 400 persons, at a cost of about £1,300. Stone is to be used throughout. Mr. T. Oliver, F.R.I.B.A., is the architect, and Mr. Thomas Turnbull, of Bertley, the sole contractor.

The foundation stone of a new English Protestant Church was laid at Point de Galle, Ceylon, on the 30th of October, by the Lord Bishop of Colombo. Mr. James G. Smither is the architect.

A pastoral letter from Dr. Manning read on Sunday last in the Roman churches in the metropolis, states that a site in Carlisle-place, Westminster, has been secured for the new cathedral, and a large amount of the purchase money paid over. The buildings to be erected adjacent to the cathedral, and which comprise a residence for the bishop of the diocese, will be executed by Mr. Gilbert Blount, and the designs for the cathedral are entrusted to Mr. Clutton. To the ability of each of these architects the letter bore marked testimony.

On Monday, the Lord Bishop of Ripon consecrated a new church dedicated to St. Thomas, at Batley. The structure consists of nave, side aisles, chancel, tower and spire, is an example of the Geometric Decorated Gothic, and has been erected from the designs of Mr. Sheard, architect, of Batley. The nave is 52ft. high, 75ft. long, and 23ft. wide, and the chancel 33ft. long by 20ft. in width, the former being divided into five bays. The tower is 20ft. square, at the south-west corner of the nave, and 150ft. high to the top of the vane. On the north side of the chancel is the organ chamber and vestry. The material used in the construction of the building is delph stone from the local quarries for the walls, and Finsdale stone for the dressings. The total cost has been about £6,000.

The first stone of the new church, Titley, Herefordshire, was laid on the 30th ult. It will replace an edifice erected a hundred years ago, and consist of nave, north aisle, south porch, chancel, organ chamber, and vestry. The present tower is to be retained. Provision is being made for 220 persons. The fittings will be of oak. Penrhos stone is being used for the walling, blue pennant for the arcade shafts, and Bath for the dressings. The walls will not be plastered internally. The style of the church is Early Decorated. The estimated cost of the work, which is being carried out by Messrs. Lewis and Day, of Hereford, is £1,600. Mr. E. Haycock, jun., of Shrewsbury, is the architect.

On Saturday, the new church of St. John the Evangelist, Lepton, Yorkshire, was consecrated by the Bishop of Ripon. The style is Early Decorated, and the plan consists of nave, chancel, and south aisle. The building seats 500, at a cost of £3,800. Messrs. Healey, of Bradford, were the architects.

BUILDINGS.

The New Metropolitan Meat and Poultry Market was inaugurated on Tuesday week by the Lord Mayor and other members of the corporation. There are 162 shops in the market, each about 36ft. by 15ft.; each shop consists of front shop, enclosed by open iron railing, and back shop, which can be entirely closed after business hours; in the back shop is the counting-house, and over it a private room, with water-closet, &c. The entire cost of the market building will be somewhat within the architect's estimate of £200,000. That the building will prove most useful, as partly supplying a great need, there can be no doubt. Of its architectural character we have already said all we care to say.

On the 25th ult., a new townhall was opened at Mirfield, near Dewsbury. The style of the building is Italian, freely treated, and the material used is stone from the local quarries. A large lecture hall containing sitting accommodation for 1,000 persons is on the ground floor. The cost of the building was £4,000. Messrs. John Kirk and Sons, of Huddersfield and Dewsbury, were the architects.

A national school building, for about a hundred children, is in course of erection in Plympton, Devon, from a design by Mr. James Hine, architect, Plymouth. The site, on the south side of the ancient castle and immediately adjoining the village Green, was given by the Earl of Morley. The style of the building is Early Pointed; the materials of the walls local stone, freestone, and Lee Moor brick. Mr. Verren is the builder.

TO CORRESPONDENTS.

To OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

RECEIVED.—L. Z.—A. H. H.—I. C. H.—O. W. D.—I. P. S.—H. W. P.—I. C. K.—W. and B.—E. H. T.—T. C.—W. H. L., with photograph.—J. C. T.—J. H.—W. and N.—E. P.—D. B.—T. T.—I. F. R.—O. W. D.—J. C. J.

J. D. M.'s letter on Local Boards next week.

A. C. G.—Next week.

G. G. H., with photographs.—We will give one of the illustrations with plan, and should like to state price as well.

QUERY.—Your going to India must depend on your inclinations, health, ability, and means.

A LOOKER ON should have put his name to his letter.

Correspondence.

MR. J. M. SMITH'S DRAWINGS.

To the Editor of the BUILDING NEWS.

SIR,—I trust that not one of your readers will endorse the remarks made by your correspondent "G. S. A." in the BUILDING NEWS of last week. His preliminary remarks are simply fanciful generalities which in themselves refute themselves. The ingenious way in which he has worked out a joke at the expense of the umbrella sticks is worthy the ingenuity of an architect, and would be extremely amusing if it were more in accordance with the fact.

When "G. S. A." uses the expression "apologetically called 'grotesques,'" I suppose he means that Mr. Smith thought his creations so ugly that, as a kind of apology for publishing them, he informed your readers that they were intended for "grotesques."

Perhaps "G. S. A." is not aware that the beauty of a "grotesque" consists in what to the uninitiated is its ugliness, but to the initiated is the quaint conventionalisation of a thing, which being a natural creation is necessarily beautiful. In fact, the whole of "G. S. A.'s" remarks are entirely away from the question until we come to his last sentence, which is evidently reserved, as an actor going off the stage loves to reserve a flowing, rhythmical, and high-sounding phrase, with which he hopes to "bring down the house." "His outlines are crude and ungraceful, his details out of proportion, and his foliage conventionalised to mechanical mannerism." These are evidently points upon which opinions may differ possibly, and I hope some of the higher members of the profession, whose opinions are well known to be worthy of acceptance, who really can appreciate the power of the Gothic "eccentricities," will stand forward and tell to the "impressible minds of young students of architecture" whether *they* agree with "G. S. A.," or whether they say with me that the designs and the descriptions which accompany them "suggest" (to use Mr. Smith's own word) that essence of art feeling and that embodiment in material of a real and soul-felt religion which had almost died out for ever with the romance and chivalry of a past age, and is now being so happily revived and so universally recognised by the people of this country.

In conclusion, I trust that your readers may for some time yet have the privilege of seeing future sketches from the pencil of Mr. Smith in the BUILDING NEWS. The approval of his own innate sense of the beautiful will, no doubt, satisfy him; and the simple fact of the designs having been admitted at all in your pages seems to me to prove that you consider them worthy of the consideration of the profession.—I am, &c.,

A. R. T.

VENTILATING CORNICE.

SIR,—Mr Potts's patent ventilating cornice is not a new invention. It is a pity indeed to patent anything for ventilation. So many minds are continually bent upon the subject, so many methods are adopted, that no person can flatter himself that he has hit upon means so novel as to secure protection. If I mistake not the House of Peers was both supplied with fresh air and ventilated from the cornice level. The principle has answered where one condition is favourable, that is, where air is not supplied to the room in any other way. In the new committee room of the Stock Exchange the fresh air enters through the cornice only, for the sashes are unusually guarded against draught, and the doors have moulded and rule-joint rebates. The vitiated air leaves through the cornice only, but, as with the fresh air, no perforations are visible (for woe to the architect who hopes that they would not be pasted up), and there are no valves. The current is self-acting, but can be quickened without machinery. The plan has certainly succeeded in this case far better than could be expected from the varied temperaments and stoutness and thinness of men, and it has not been altered in the least from my first arrangement. Mr. Potts's cornice may answer the purpose; but he cannot claim the invention, nor can I.—I am, &c.,

J. J. COLE.

New Court, Throgmorton-street, E.C., Dec. 1.

SOCIETY OF ENGINEERS.

SIR,—I trust you will allow me, through the medium of your paper, to call the attention of the members of the Society of Engineers to the balloting list of proposed new members of council for the ensuing year. There are seventeen candidates and twelve only can be elected. The outgoing council have as usual nominated themselves with one or two exceptions, and will no doubt vote for each other, and get their friends to help them to get returned. I beg to suggest that, following up the Conservative tactics, members should plump for eight candidates, including the five new candidates not in the outgoing council's list. This will ensure the return of the new candidates, and infuse new blood in the council, which I need hardly say is much required.—I am, &c.,

A MEMBER OF MANY YEARS' STANDING.

Intercommunication.

QUESTIONS.

[1157.]—A QUESTION FOR SCHOOL BOYS.—Can any of your correspondents give me the solution of the following?—The copper sheathing of the hull of a vessel which had been seven years in the Pacific was found to contain 1-2,500 of its weight in silver. What fraction of a pound troy of silver would 1 cwt. of the sheathing contain?—F. A. E.

[1158.]—COMPOSITION LETTERS ON STONE.—Will any of your numerous readers be kind enough to inform me what kind of composition is used to fill up letters on stone, so that they look well and are durable.—IGNORAMUS.

[1159.]—ESTIMATES OF CORRESPONDING AMOUNTS.—As a constant reader of your paper, may I beg of you to inform me [illegible] your next issue how an architect [illegible] to settle matters when out of several tenders presented to him the two lowest [illegible] whether a [illegible] tenders [illegible]. If yes, by whom. I ask this question for the public in general.—A CONSTANT READER.

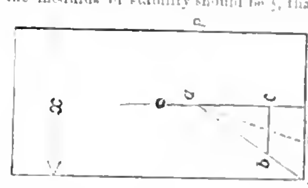
[If an architect reserves to himself the right of not necessarily accepting the lowest or any tender, he has liberty to select from the two contractors (whose tender is the same) the person whom he considers most competent to carry out the work. If he has no [illegible] this matter, call the two contractors together, and let the question be decided by lottery.—ED. B. N.]

[1160.]—GLAZED BRICKS.—Can any correspondent inform me where glazed bricks 11in. long can be procured and the price? I saw them advertised somewhere once for bonding together 2ft. 4½in. hollow wall.—I. E. H.

[1161.]—PRACTICE OF THE PROFESSION.—Can you, or any of your readers, inform me what is the practice of the profession in the following cases?—1. When a quantity surveyor has supplied quantities for a job, which, the tenders having been received, is found to cost too much, and is therefore abandoned, who pays him for his labour in that case? 2. Or, when the job goes on in part, or on a reduced scale, and the original quantities are set aside, the builders tendering in the second instance on their own quantities, or on what they can make out of the original ones, how is the said surveyor to be paid in that case? On the amount of lowest tender based on the original quantities, or on the amount of the actual work (building work, that is) carried out?—M. K.

REPLIES.

[1080.]—RETAINING WALLS.—The corrections given by "X + Y" to the several expressions on my solution of his problem on the stability of retaining walls are correct, the errors being misprints. In calculating the thickness of a safe wall, the moment of the earth should be doubled, or = 2O, and I will give him the reason why. Let the line a c represent the weight of the wall, and b c the pressure at P. Then the resultant a b, when the wall is in equilibrium, will cut the toe of the wall at d; but for a safe wall the modulus of stability should be ¾, that is, the resultant should cut a point p, equidistant from d and f, therefore weight of wall × distance p f must equal O. Thus the equation for a rectangular wall on equilibrium would be



$O = h\ w\ x \times \frac{x}{2}$, and for stability, $O = h\ w\ x \times \frac{x}{4}$, or its equivalent $2O = h\ w\ x \times \frac{x}{2}$. h = height of wall; w = weight per cubic foot; x = thickness.—J. L.

[1080.]—There are some mistakes in the printing of part of my letter of November 27.

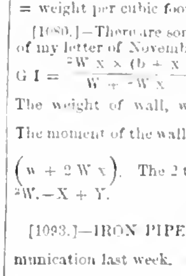
$G\ I = \frac{{}^2W\ x \times (b + x}{W + {}^2W\ x}$ should be $G\ I = \frac{2\ W\ x \times (b + x)}{W + 2\ W\ x}$

The weight of wall, $w + {}^2W\ x$, should be $w + 2\ W\ x$

The moment of the wall should be $\left(\frac{2\ W\ x \times (b + x)}{w + 2\ W\ x} + a\right)\left(w + 2\ W\ x\right)$. The 2 throughout in 2 W has been printed ²W.—X + Y.

[1093.]—IRON PIPES.—There is a misprint in my communication last week. $A = \frac{area \times 16}{20}$ $c = 80$, should be $A = \frac{area \times 16}{29}$ $C = 80$.—J. L. (signed W. P. in error.)

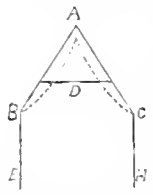
[1112.]—STRENGTH OF WALLS.—I have mislaid my number of the BUILDING NEWS containing the question put by "Inexperience," therefore cannot refer to it, but my attention is drawn to the information offered by "Heyton" in last week's issue. Before "Heyton" attempts to instruct "Inexperience" he should possess [illegible] of more accurate knowledge [illegible] subject in hand, and [illegible] perpetrate such absurdities [illegible] in his communication, which can only tend to bewilder [illegible] mislead. In the first place, [illegible] does not appear to know where the centre of gravity of the wall lies, neither has it a tendency to turn over on the point A, as he states, and his equation for the thrust and resistance is simply a "muddle."



If T represent the horizontal thrust at the top of the wall, T × H will express the value of the force tending to turn it over on the point b, and if W = the weight of the wall, W × a [illegible] will express its resistance, therefore the equation for thrust and resistance in equilibrium will be T × H = W × a b.—J. L.

[1122.]—ROOF CONSTRUCTION.—"A. F. [illegible]" and "H." are both of them in the dark as to the purpose for which a collar beam is used. They mistake it for a tie beam, and erroneously assert the strain to be a tension. The one other portion of roof framing with which a collar beam may be compared is the straining beam of a queen

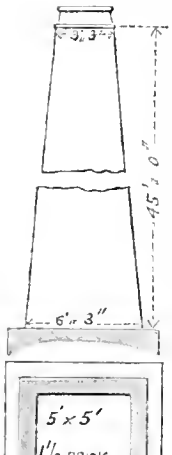
post truss; the longitudinal strain in each being that of compression. In the annexed diagram, A B and A C are the rafters, D the collar, B E and C H the walls. Suppose the collar to be taken away, then the tendency of the rafters will be to assume a curved form, the point A being depressed, as shown by the dotted lines. To prevent this sagging of the rafters, the collar beam D is introduced, and clearly the force it resists is one which compresses it. Tensile strain in a collar beam will occur when the walls have not sufficient stability to resist the outward thrust of the rafters; which would be an example of bad construction, and would prove the designer to have been incompetent or careless. The method suggested by "H." for keeping the thrust off the walls is not a good one, the connection of the strut with the principal is faulty, and, without bracing, the strut would soon cease to be of any utility. The king post might very well be dispensed with. The iron tie rod, which "H." rejects, would be much more effective; its variation from a mean length would never exceed, in this country, the 1-32nd of an inch.—PUBLIN.



[1122.]—Allow me to thank your correspondents for their replies to my questions, and in answer to "D. Y." I

have sent the attic plan. The ridges are shown by dotted lines.—BEGINNER.

[1118.]—SHAPE OF CHIMNEYS.—I should advise "Builder" to build his chimney square on plan, as that is a stronger form than the circular one. Moreover, while there have been abundant instances of circular chimneys falling down, the examples of square ones coming to grief in the same manner are very rare. The annexed is a plan and elevation of what I should recommend as good proportions. If the thickness at the ground level be a brick and a half, it may be diminished to one brick at the top. The foundations and footings must depend upon the nature of the ground. It is not generally adopted, but "Builder" will find that a cast-iron cap makes a very good finish to a chimney, much better than any ordinary coping. For small chimneys intended for temporary purposes, not exceeding 25ft. or 30ft. in height, the corners are sometimes protected by longitudinal angle irons, into the sides of which the abutting bricks fit. Several of these have been erected at the Royal Arsenal at Woolwich, for the furnaces where the coils forming the body of the Fraser gun are heated before being forged under the tilt hammer. When a chimney is very lofty, the accurate determination of the best curve for it is a very difficult mathematical investigation, as the effect of the wind must be allowed for.—P. B. STRUT.



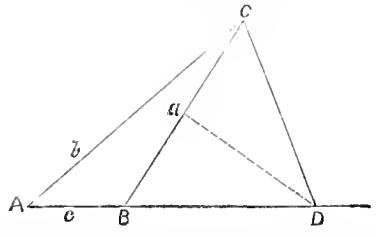
[1128.]—CALCULATION OF PRIME COST.—I have generally found that the expenditure on works could be conveniently calculated, as shown by the following example, in which I suppose the contract to be for £600, and I assume the expense of each item:—

	£	s.	d.
1. Paid for labour, as per foreman's weekly returns	120	0	0
2. ,, materials (not plant)	380	0	0
3. ,, carriage of same	10	0	0
4. Value of materials (not plant) supplied from stock	20	0	0
5. Carriage of same	1	0	0
6. Surveyor's fees, licences, and other like incidental expenses	10	0	0
7. Travelling expenses	3	0	0
8. Deterioration in value of plant	10	0	0
9. Carriage of same	3	0	0
10. Proportion of yard and office expenses, and time of general foreman, due to amount of contract	9	12	0
11. Loss of interest on sums drawn for payments	15	0	0
	£581	12	0
	£	s.	d.
12. Value of surplus materials (not plant) returned to stock, less cost of carriage; or sum realised by sale of same	15	0	0
13. Amount of contract	600	0	0
14. Interest gained on instalments	10	0	0
	£625	0	0

Shows a gain of.....£43 8s. 0d. H. C.

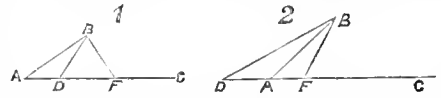
[1128.]—I think the reply sent by Mr. Duffield is somewhat overstrained. Not contented with telling your correspondent that he kept a separate heading or folio in his ledger for each contract or customer (strange book keeping if otherwise), he asserts that he can tell the prime cost of a £600 job to a shilling. When Mr. Duffield sends from his shop any joiner's work does he mean to say that every 1 in board taken from seasoned stock and cut into stiles and rails, that he knows whether that board came from deals at £21 per 100 or £22? Also, short ends cut up, he can identify their prime cost per 100. Also, when he sends out cut nails, does he know those he bought at 12s. 6d. from those at 11s. 6d.? Again, how does he manage so exactly the prime cost of the wear and tear of scaffolding? Say two jobs are in progress, one at £2,000, another at £4,000; the wear and tear of scaffolding may be greater at the smaller job from the nature of the works. I know an average per centage may be put on, but this is not the point. Mr. Duffield asserts that he can tell the prime cost to a shilling. As this is bringing accounts to a mathematical nicety, perhaps Mr. D. will enlighten—A GUILDER'S CLERK.

[1123.]—TRIANGLES.—Assuming that your correspondent "R. F." intends the sides of his triangle to be measured in feet or other lineal units, and not in degrees, as printed, I offer the following as a simple solution by construction, in the case where the base A D exceeds the side C D. On A D, as a base, set up A C at an angle of 40 deg.: make A C = 30, and on A D mark off A B = 10, the difference between the two sides whose lengths are sought, and join B C. Bisect B C in a, and draw a D perpendicular to B C, and meeting A D in D. Then will A D C be the triangle required, having the side A C = 30, the angle at A = 40 deg., and the difference of the sides A D, C D = 10. This construction at once suggests the trigonometrical solution, as follows:—1. To obtain the magnitudes of the angles A C B, A B C; putting a for the side B C, b for the side A C, and c for the base A B; also denoting the angles at A, B, and C by those letters, we have—As $(b+c)$ is to $(b-c)$ so is $\tan.\frac{B+C}{2}$ to $\tan.\frac{B-C}{2}$.

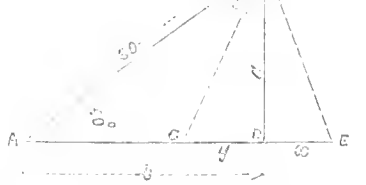


This gives the angle B = 123° 57', and that at C = 16° 3'. 2. To find the length of the side a—As sin. 16° 3' is to c, so is sin. 40° to a; whence a is found to be = 43.25. 3. We now proceed to find the length of the side B D or C D. By the construction they form the sides of an isosceles triangle, which has B C for its base; consequently the angles C B D and B C D are equal. But the angle C B D = 180° − 123° 57' = 56° 3'. Therefore the angle B C D = 56° 3', and the angle at D = 180° − (56° 3' + 56° 3') = 67° 54'. Then, as sin. B D C : B C : : sin. B C D : B D. Whence 20.81 is found to be the length of the side B D or C D. Consequently, the three sides of the required triangle A D C are respectively 30, 30.81, and 20.81; and the angles are 40°, 67° 54', and 72° 6'.—E. SWANBOROUGH.

[1129.]—Not seeing in the last number of the BUILDING NEWS any, as I considered, satisfactory answer to this question, I thought the following might be acceptable to "R. F." First—Supposing A C to be the longest side, from A C cut off A D = 10; join B D; at point B make the ∠ D B F = the ∠ B D C. Then B A F is the triangle required. Secondly—Let B F be the longest side. Produce F A to D, making A D = 10; join B D; and at point B make the ∠ D B F = ∠ B D F. Then B A F is the triangle required.—C. P. E.



[1129.]—With the conditions given in the problem supplied by "R. F." the remaining sides, which may be either A C and B C, or A E and B E, may be easily found



in the following manner:—The expressions for the several lines in the figure will be as under—

B D = 30 × nat. sin. ∠ 40° = 19.28 =	a.
A D = 30 × nat. sin. ∠ 50° = 22.98 =	b.
C D =	y.
D E =	x.
A C =	b − y.
B C = (c = diff. in the two sides)	b − y + c.
A E =	b + x.
B E =	b + x − c.

Having these expressions, it is only necessary to know the values of x and y to solve any one of them: and

$$x = \sqrt{(b+x-c)^2 - a^2} = \frac{a^2-(b-c)^2}{2(b-c)} = 7.83$$

$$y = \sqrt{(b-y+c)^2 - a^2} = \frac{(b+c)^2-a^2}{2(b+c)} = 10.85$$

Thus: A C = b − y = 22.98 − 10.85 = 12.13.
B C = b − y + c = 22.98 − 10.85 + 10 = 22.13
A E = b + x = 22.98 + 7.83 = 30.81
B E = b + x − c = 22.98 + 7.83 − 10 = 20.81.
—J. L.

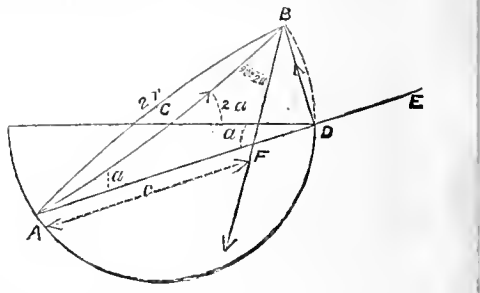
[1129.]—In reply to "F. R.," who styles himself a mathematician, I beg to say that his question is by far the most ridiculous I have ever seen. "R. F." should be careful in writing about the great sciences of mathematics, for if he only knew the unlimited value of things of so great moment, which even teaches to demonstration the art of investigating the motions and magnitudes of the starry firmament, he would not put questions to which no meaning can be attached; for, in the first place, to reason logically, a geometrical question is a problem, and a problem is something proposed to be done—that is, certain things or quantities are given to find out others, and this is called a solution. Now, your correspondent gives certain things for solution without saying what he really wants solved. In the second place he talks of triangles, and in his diagram draws only an angle. Now, a triangle is a superficies, but two straight lines agreeable with Euclid cannot enclose a space. In the last place, the measurement of lines are always taken by some unit, and it is the angles of a figure only which are taken by degrees. Let "F. F." think himself no more a geometrician, for be it well known, from the following lines, that the subject is based on really profound facts and not on farces:—

"He who thro' vast immensity can pierce,
See worlds on worlds compose one universe,
Observe how system into system runs,
What other planets circle other suns,
What varied Being peoples every star,
May tell us why our Maker made us as we are"

ROBIN CARPENTER.

[Answers to this question have also been received from "Martin B." and "Calculator."—ED. B. N.]

[1135.]—QUESTION IN STATICS.—Let A D E be the position of the rod; draw a diameter A B; join B D; then will B D be perpendicular to A D; and the reactions of the surface of the bowl and the point D will be in the directions A B and B D; a vertical line drawn from B will pass through the centre of gravity of the rod, which will be at its middle point. Let R = reaction in direction A B; R' in direction B D; A F = C. Now the angle C A D = a = angle C D A ∴ angle B C D = 2a, and the angle C B F = 90° 2a. Resolving horizontally, and taking moments round F, the following equations are obtained: (1) R cos. 2a = R' sin. a; (2) R' × F D = R A F sin. a, but F D = A D − A F = 2r cos. a − c ∴ R' (2 r cos. a − c) = R × c sin. a. Multiplying both these equations together, and reducing, we get 4 r cos. ^{2}a − c cos. θ − 2 r = o, which gives a quadratic for angle a. In this question r = 2 c = 2½. Substituting these values, and solving, we get



$$\text{Cos. } a = \frac{5}{32} = \sqrt{\frac{537}{1024}} = .8804143,$$

which is the natural cosine of the angle, ∴ a = 28° 18' 29"; now F D = 2 r cos a − c = 4 × .8804143 − 2.5 = 1.0207'. This result can be verified by plotting it to scale.—C. D.

LEGAL INTELLIGENCE.

BAD SLATES.—On Saturday an adjourned sitting of the Stockton County Court was held, and the case of Crossley *v.* the Liverton Ironstone Mining Company was disposed of. The plaintiff, who is a dealer in building materials at Stainton, sought to recover £17 13s. 8d. for slates alleged to have been supplied to the defendants. On April 13 last the defendants ordered 1,500 square feet of slating and 46ft. of ridge roll. On April 27 the manager of the Ironstone Company wrote to the plaintiff, stating that the slates were so inferior in quality that they could not use them, and offered to return them. Afterwards the manager said he would keep the slates on consideration that the price was reduced. The plaintiff saw the importer of the slates, and he consented to a reduction in price rather than receive them back. On July 9 plaintiff received a cheque from the defendants for £1 8s. in payment of the ridge roll only. Plaintiff then wrote to the manager reminding him that he had agreed to keep the slates at a reduced price. In reply to this the manager wrote offering to pay the carriage if the plaintiff would take back the slates. Plaintiff refused to do this, but in September the slates were returned. His Honour gave a verdict for £1 8s. without costs, the price of the ridge roll only.

THE WANDSWORTH BOARD OF WORKS (APPELLANTS) *v.* HALL (RESPONDENT).—The respondent in this case had been summoned by the Board of Works, on the ground that he had built in front of Thurlow Cottage, Wandsworth-road, beyond the general line of building frontage. It happened that at the time the respondent built, the architect of the board had not actually laid down any building line at the spot in question; and the magistrate held that under these circumstances he had no power to interfere and order the demolition of the plaintiff's building, and he dismissed the complaint. The question for the Court of Common Pleas, where the appeal was, was whether the magistrate had power to make the order for demolition. The court held that if a man built beyond the proper building line, and the line was afterwards fixed by the architect of the board, the magistrate had power, notwithstanding the line was not laid down until after the building was erected, to order the demolition of the building. Judgment for the appellants.

THE METROPOLITAN BUILDING ACT.—Mr. Ashley, builder, No. 20, Grafton-street, was summoned by Mr. Baker, district surveyor of St. Pancras, on Monday, before the Marylebone Police Court, for constructing a wall with broken bricks not put together with proper mortar or cement. Mr. Venn appeared for the defendant. After the evidence had been heard it was agreed to refer the case to some competent person, and Mr. Caiger, the police surveyor, was named by the magistrate and accepted by both parties. Mr. Caiger having made the necessary inspection, said he had found that the wall had not been built according to the requirements of the act, and he considered that it ought to be pulled down. An order having been made for the wall to be pulled down costs were applied for. Mr. Tyrwhitt acceded to the application, and in addition to a nominal fine of 1s., ordered the defendant to pay £4 8s. costs.

Our Office Table.

Within the last few days several of the grand marble tableau, executed in inlay work by Baron Triqueti, and intended for the decoration of the Albert Memorial Chapel, have arrived at Windsor Castle. Two of them have been placed in their proper positions on the south wall of the interior of the chapel. The first to be noticed is that contributed by her Royal Highness Princess Louise of Hesse. The subject is "Pharaoh creating Joseph Viceroy of Egypt." The next tableau, upon the south wall, is "The offering of the first-born of the Queen and the late Prince Consort." It is presented by her Royal Highness the Crown Princess of Prussia. The subject selected for Princess Victoria's tableau is "Jacob blessing the Sons of Joseph." Only a portion of the Princess of Wales's offering has yet reached the Castle.

A report has been published on the tin and tinued vessels used in the military hospitals in France. The metal used for tinning, it was found, contained from 25 to 50 per cent. of lead. In vessels reputedly made of pure tin, the commissioner found, in some cases, as much as 15 per cent. of lead. Such proportions are dangerous, he says, to the public health, and the Government is recommended to fix a standard allowing only 5 or 6 per cent. of lead to be used with tin in utensils intended for culinary purposes or for drinking vessels. The author has probably overstated the dangers from the use of utensils composed as he has found; but it would be well if cheap manufacturers in this country would bear in mind that it is not altogether safe to use a large proportion of lead.

A report from Dingle states that an extensive and valuable bed of slate, extending over several hundred acres, has been discovered close to the seashore at Dunarlin, in the extreme west of Kerry, and on the estate of Lord Ventry. Competent authorities announce the material to be of the best quality.

The eleventh annual meeting of shareholders in the Architectural Union Company was held on Wednesday at the offices, 9, Conduit-street, Regent-street; Mr. Charles Mayhew in the chair. Mr. Farthing, the secretary, read the report, which stated there was again an increase in the receipts from the rentals of the several rooms and galleries during the past year, and the financial position of the company was in the most satisfactory state. The total receipts for the year had been £1,803 4s., and the expenditure £1,197 10s. 7d., leaving a balance of £605 13s. 5d. The directors recommended a dividend of 10s. per share, being at the rate of 5 per cent. per annum, which will amount to £518. The number of shares now on the register was 1,037, upon which £10,370 had been paid. The chairman, in moving the adoption of the report, which was agreed to, congratulated the shareholders upon the steadily increasing improvement in the affairs of the company. Messrs. Ashfield, Lamb, Wood, and Wylson, the retiring directors, were re-elected; and Messrs. Lockyer and Cockerell were re-elected as auditors.

The medical officer to the Shoreditch vestry (or "Shoreditch Representative Council," as a local print magniloquently terms it) has reported on the dirty and dilapidated condition of a number of houses in Charlotte-court, Charlotte-street, Curtain-road, in accordance with the provisions of the Artisans' Dwellings Improvement Act. The houses are described as unfit for human habitation. The consideration as to the enforcement of the Act by the vestry is postponed till January.

A suggestion is made by one of the correspondents of the *Pall Mall Gazette*, for preventing accidents to railway travellers on the arrival or departure of trains, and rendering it unnecessary to lock the carriage doors. It is as follows, and seems, at any rate, worth a trial:—To the edge of the platform fix a barrier or railing, to rise and fall on the principle of a parallel ruler. At the sound of a gong the barrier could be raised for the whole length of the train, thereby preventing any reopening of the carriage doors at departure. The train could enter the arrival platform between barriers up on both sides, and passengers might be allowed to let themselves out on the side from which the barrier had been depressed at the stroke of the gong.

A large square of buildings was erected about twenty years ago in Albert-street, Spitalfields, under the patronage of the Earl of Shaftesbury, and was set apart for the accommodation of single men. Although one of the most commodious buildings of the kind, possessing a large reading room and lecture room, with accommodation for 210 lodgers, it has not latterly paid sufficient to clear the current expenses. It is, after being closed for a short time, in the course of refitting as a lodging house for families, and when completed it is expected to return 7 per cent. on the capital invested in the erection of the building.

The part of the approach to the New Meat Market east of Farringdon-road was opened for carriages on Tuesday morning. One of the water companies took the opportunity of opening the roadway of the section west of Farringdon-street (leaving room for one line of vehicles to pass) *on the same morning*, having neglected availing themselves of the six weeks' time they had had to effect their purposes.

Mr. George Martin, of Stockton-on-Tees, sends us the following on preparing paper for drawings:—Perhaps it may not be thought superfluous to point out to beginners that in stretching paper for show, or indeed any drawings, care should be taken to see that no part of the paper be secured to the clamps at the end of the drawing board, as these, being placed with the grain in a different direction, the expansion or contraction, or pinning, is not in harmony with the rest of the board, and the paper would be affected by the difference. Water colour painters recommend that the half inch to be glued should be doubled over upwards while wet, so as to be better got at in applying the glue. It is also recommended that after fixing the first side, the opposite one should be done, as twisting of the paper would be less likely to occur. These are, apparently, trivial matters, but attention to such may sometimes save a great deal of trouble.

The treasures of the Royal Irish Academy have just been enriched by a donation from the Earl of Charlemont. It is a collection of seventy-four terra cotta busts of the Roman emperors and their families, modelled from the original antiques in the capitoline museum at Rome, and which long adorned the library at Charlemont House. They are upwards of a century old, having been executed at Rome in the year 1754 for Mr. Edward Murphy, a gentleman of great literary and artistic ability, by an eminent Roman statuary, named Vierpyle.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Society of Engineers.—Paper on the "Accumulator Cotton Press," by Mr. E. Matheson, and on the "Application of Steam to the Cultivation of the Soil," by Mr. B. Latham. Entomological Society, 7.

TUESDAY.—Institution of Civil Engineers.—Discussion upon Mr. Wheeler's paper on "The River Witham and its Estuary."

WEDNESDAY.—Society of Arts.—"On the Theory of Boiling in connection with some Processes in the useful Arts," by C. Tomlinson, Esq., F.R.S., F.C.S.

Geological Society, 8.

FRIDAY.—Architectural Association.—"The Architecture of Russia," by E. I'Anson, Esq., F.R.I.B.A.

SATURDAY.—Associated Arts Institute.—Paper "On the Treatment of Subject in Pictorial Art," by R. Redgrave, Esq., R.A.

Trade News.

TENDERS.

LONDON.—For new sewers in the Western Districts, and filling up open ditches in Wood lane, and Lawn-place, Shepherd's bush:—

SLOUGH.—For the erection of four houses at Slough, for Mr. J. Foster. Drawings made by Mr. Pierse Arthur.

Evans	£[illegible]
Jones	750
Shaw	710
Johnson	710

WOLVERHAMPTON.—For alterations and additions to the Wolverhampton Union Workhouse. Mr. J. R. Veall, architect:—

Crutchley	£1023 0 0
Lovatt	979 7 10
Thompson (accepted)	960 0 0
Bowater	950 0 0

COMPETITIONS.

INDIA.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

PRIORY ESTATE, DOVER.—December 15.—For laying out about 13 acres of building land. Premiums of 50 and 25 guineas. Mr. S. Finnis, Biggin-street, Dover.

SOUTH METROPOLITAN SCHOOLS, SUTTON (Surrey).—February 2.—For designs for the erection of an infant establishment adjoining the present schools. Premiums of 10 guineas each for the three designs considered the best. J. Burgess, clerk to the managers, Vestry Hall, Walworth.

HARTLEY, WINTNEY, HANTS.—December 29.—For plans and specifications for the erection of a new church for the accommodation of about 700 persons. Mr. Wetherell, Hartley Wintney, Winchfield, Hants.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

HAMPTON COURT AND WALTON BRIDGES.—December 16. Tender for tolls. Mitre, Hampton Court.

ST. JAMES'S CHURCH, GREAT YARMOUTH.—December 12. —For the erection of a portion of this church. J. P. Seddon, architect, 12, Park street, Westminster.

ST. MARY ABBOTT, KENSINGTON.—For the construction of about 1,100ft. of brick sewer. Mr. J. Whitchurch, surveyor, 7, Lincoln's Inn Fields.

LEICESTER WATERWORKS.—December 8.—For the execution of the works comprised in Nos. 4 and 5 contracts. J. H. Williams, secretary.

BARFORD.—For the erection of hospitals and other buildings in connection with the union. R. B. Spencer, clerk to the Guardians.

For the purchase of old bricks, bats, chalk, oak, &c.—Messrs. M. T. Shaw and Co., 141, Cannon-street.

LEWISHAM.—For the construction of six houses.—W. C. Banks architect. 39a, Gracechurch-street, City.

CLEATON MOOR WATERWORKS.—December 12.—Contract C, for excavating ground, &c. Contract D, for supply of cast iron water pipes, &c. Contract E, for supply of sluice valves, hydrants, &c. Contract F, for the construction of a service reservoir, &c. Contract G, for the supply of about 1,550 yards of earthenware pipe. J. Anderson, clerk to the local board, Cleaton Moor.

ST. GILES, CAMBERWELL.—December 8.—For the purchase, collection, and removal of dust, &c. G. W. Marsden, vestry clerk.

LEICESTER WATERWORKS.—December 8.—For the construction of a large storage reservoir, &c., and for the erection of an engine and boiler house, and other works. J. H. Williams, secretary, Waterworks offices, Bowling Green-street, Leicester.

WOOLWICH.—December 12.—For purchase of 100 tons of steel turnings. T. Howell, director of contracts, Pall-Mall.

PROPERTY SALES.

NOVEMBER 25.

AT THE MART.—By Messrs. Candy and Luckin.—Freehold residence, No. 23, British street, Bow road, let at £26 per annum—sold for £280.

Freehold residence, No. 25, British street, let at £25 4s. per annum—£285.

Freehold residence, No. 29, British street, let at £26 per annum—£290.

Freehold residence, No. 31, British street, let at £26 per annum—£2 5.

Freehold residence, No. 35, British street, let at £26 per annum—£300.

Leasehold house, No. 154, Weedington road, Prince of Wales road, Kentish Town, let at £33 per annum, term 99 years from 1847, at £7 per annum—£235.

Leasehold house, No. 156, Weedington road, let at £33 per annum, term and groundrent similar to above—£240.

Leasehold eight houses, Nos. 1 to 8, Nelson place, New street, City road, with workshops and chapel in the rear, producing £115 8s. per annum, term 21 years from 1866, at £92 per annum—£500.

Leasehold eight houses, Nos. 1 to 8, Garden row, Livre street, City road, producing £111 16s. per annum, term 21 years from 1866, at £56 per annum—£230.

At the Guildhall Coffee-house.—By Messrs. Furber and Price.—Leasehold groundrent of £14 per annum for 18 years, arising from Nos. 157 and 159, Fulham road—£120.

NOVEMBER 26.

At the Mart.—By Mr. A. Booth.—Leasehold residence, No. 34, Thurloe square, term 59 years from 1868, at £8 per annum—£3,200.

By Messrs. Price and Clark.—Leasehold residence and business premises, No. 31, Murray street, New North road, let at £70 per annum, term 99 years from 1843, at £5 2s. per annum—£910.

By Mr. Newbon.—Copyhold house, No. 16, Collingwood street, Mile end road—£162.

Leasehold residence, No. 22, Citizen road, Hornsey road, let at £30 per annum, term 80 years from 1862, at £5 per annum—£255.

At Garraway's.—By Mr. F. I. Sharp.—Leasehold 16 messuages, Nos. 1 to 9, Solomon's row, and Nos. 1 to 7, Solomon's place, Chatham, Kent, producing £157 6s. per annum, term 52 years from 1857, at £11 4s. per annum—£740

Leasehold four cottages, Nos. 3 to 6, Queen street, Camberwell, producing £51 7s. per annum, term 53¼ years from 1823, at £3 annum—£120.

Leasehold three residences, Nos. 34, 35, and 37, Cavendish street, New North road, let at £32 per annum, term 21 years from 1867, at £3 each per annum—£215 and £240 each.

By Mr. Lerew.—Freehold groundrent of £13 per annum, secured on Nos. 1 and 2, Alexandra villas, Palace road, Wood green—£260.

Freehold groundrent of £13 per annum, secured on Nos. 3 and 4, Alexandra villas—£260.

Freehold groundrent of £6 10s. per annum, secured on No. 5, Alexandra villas—£130.

Freehold eight plots of land fronting Palace road, Wood Green—£42 per plot.

Freehold four plots of land fronting Park road, Wood Green—£40 per plot.

NOVEMBER 27.

At the Mart.—By Messrs. Wilkinson and Horne.—Leasehold six houses, Nos. 1 to 6, Hornsey place, West Ferry road, Millwall, Poplar, producing £144 6s. per annum, term 70 years from 1848, at £15 per annum—£750.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

Robert Arrow, St. Paul's Cray, builder, December 9, at 11—Philip Fuller, Boughen Croydon, builder, December 10, at 11—Anthony Ellis, Lorrimore street, Walworth, builder, December 9, at 12—George King, New Cross, builder, December 18, at 2—George Alexander Croke Stoddart, Colney Hatch, carpenter, December 9, at 1—David Prentice, Lordship lane, Dulwich, builder, December 17, at 2—Joseph Tapner, Euston road, decorator, December 14, at 1—Joseph Thornton, Plaistow, contractor, December 21, at 1—Joseph Ward, Worthing, builder, December 21, at 12.

TO SURRENDER IN THE COUNTRY.

Joseph Coulson, Bolton, builder, December 9, at 10—Edwin Elton, Derby, builder, December 9, at 12—John Norcliff, Mytholmroyd, stonemason, December 10, at 11—Richard Berry Talbot, Stafford, builder, December 11, at 12—Joseph Hawkford, Aston, near Birmingham, carpenter, December 11, at 10—William Cooper Howes, Norwich, plumber and glazier, December 10, at 11—George Vidler, Battle, plumber and glazier, December 12, at 11

NOTICES OF SITTINGS FOR LAST EXAMINATION.

December 14, J. Peters, Bristol, carpenter—December 14, G. Beard, Horton, near Chipping Sodbury, timber dealer—December 14, G. V. Broad, Horfield, Gloucestershire, builder—December 17, H. Thomas, Maesteg, carpenter—December 16, J. Richards, Plumstead common, painter and glazier—December 16, W. J. Baker, Jubilee street, Commercial road, East, painter—December 18, F. Beach, Hornsey road, stonemason—December 18, A. Hinkley, Sittingbourne, brickmaker—January 12, A. Munsey, Acton, architect—January 12, W. Stevens, St. John street, Smithfield, gasfitter—January 20, J. Emson, Wolverhampton, gas engineer—January 12, J. Woolfrey, Taunton, builder—December 16, J. Chesworth, Liverpool, builder—December 16, R. Martin, Liverpool, builder—December 17, W. Baxendale, Manchester, joiner—December 22, H. Halton, Hyde, joiner—December 28, J. Lee, Primrose hill, near Huddersfield, stonemason—December 9, C. J. Webb, Springborne, Hants, painter—January 12, W. H. Rankin, Westminster Chambers, Victoria street, civil engineer.

PARTNERSHIPS DISSOLVED.

Gray and Co., Heaton, Yorkshire, stone merchants—Moulson and Kay, Little Horton, builders—Moore and Co., South Shields, glass manufacturers—Smith and Grace, Thrapstone, engineers—W. and E. Shelbourne, Fore street, Limehouse, contractors and lightermen—Schofield and Son, Oldham, timber merchants.

DIVIDENDS.

December 16, J. Lucas, Oxford street, glass merchant—December 15, W. Meatyard, Mere, Wilts, carpenter—December 10, W. Tyson, Wavertree, joiner—December 19, E. J. Wyles, Brighton, builder.

DECLARATION OF DIVIDENDS.

T. Allen, Great Smith street, Westminster, and Hertford, builder, div. 3s. 4d.—R. and J. W. Worswick, Ipswich, builders, div. 4s. 10d. and 11s. 9d.

SCOTCH SEQUESTRATION.

Thomas Allardice and David Napier, Dundee, builders.

THE BUILDING NEWS.

LONDON, FRIDAY, DECEMBER 11, 1868.

AN ESTIMATE OF THE PROGRESS OF DESIGN AND DECORATION.

IN order to understand our position and prospects in design our only safe course is to ascertain what we have already accomplished. The favourite way, however, used to be, and is, to turn back to some epoch of art in Greece, in Italy, or in mediæval Europe, regard what was then done, and recommend our doing the same. As the circumstances, if even known, are not even the same as ours, these comparisons and recommendations are not attended with fruitful results. There is not the least harm in our aims being high, but it is evident, whatever our ambition, we are really limited by our means. Therefore it will be well to make our survey of what has been done rather in our own time and in one generation than in the remote past. In fact, the reign of Victoria will give us enough to do, being a generation and a little more. To a certain extent, although it continues the Georgian era, to which may be annexed the reign of William IV., it constitutes in its development a new epoch. The period of the Regency and George IV. is pretty well marked out—one of brilliancy and beauty, but in architecture not of solidity; in sculpture, unable to compete with Canova and Thorwaldsen; and in painting, holding its own even way without achieving excellence. We can draw a line pretty well between the middle era of George III. and the Georgian era of the Regent. We have the time of Pitt, Fox, Nelson, Herschel, Flaxman, Barry, Southey the poet, Kemble, and their foils, Earl Chatham and that brood which developed into Liverpool, Sidmouth, and Castlereagh. It was a time of noble effort for Classic excellence, one as well typified by Flaxman as anyone else, of whom we have noble designs, lessons to Europe, and few monumental works; or by Barry, who showed how to create great examples in art, though he could not satisfactorily work out his teachings.

We may mark the men of George the Regent, not forgetting the Regent himself, and, though we bring Wellington into the gallery, there is less severity than in the foregoing era, but more markedly that beauty which is shown in their portraiture by their true painter, Lawrence,—Wellington (the statesman rather than the warrior), Canning, Mr. Brougham, Byron, Scott, Moore, Shelley, Jeremy Bentham, Davy, Wilkie, Haydn, Martin, Turner, Chauntry, Kean; and its architects were Nash and Smirke. We have given many great names, but we believe their architecture has its connection with the moral aspect of the era, when the period was one of political agitation and of political projection, leaving the realisation for the future, and when Nash conformed to the instinct of the day for beauty but wrought out in compo. It was an age less, perhaps, of sham, as it has been reproached, than of inadequate resources. The whole country was cramped by the exhaustion and exactions of the Great War, the evils of which long continued to affect society, as its legislation with regard to window and brick duties, excises on paperhangings, and taxes on glass, affected the architect and his employer at every turn. The enterprise of the country was not emancipated and restored to the freedom it possessed before the great revolutionary war, and, although there were bold spirits and bold individual attempts, there was a want of general and collective power. The progress of particular branches of industry is apt to blind us to the conditions affecting the mass. To go down to the working classes it was a time of dear bread, dear groceries, dear candles, and the earnings of some of the new trades of engine-wrights and gasfitters only relieved the misery of some portion of the ranks. This was, after all the real picture of society, though there were men making colossal fortunes in the application of some of the new inventions. There was a want of vigour, consequently, in the body politic which reacted on art. There was no money in the exchequer for art; jobbery had too material interests. Jobbery lent itself by its own instinct to the reconstruction of Windsor Castle and Buckingham Palace for its chief patron, to the building of York or Sutherland House for a satrap; but as the funds were provided by jobs, so were the supplies cramped.

These are moral aspects but little regarded by the critics on art, and we think it worth our while to refer to them, and in so doing notice an apparent anomaly and exception. During the Great War, which in its main effects continuously exhausted and oppressed the country, there was great vigour in the manifestations of the public mind in literature, in art, and in the drama, as much as on the ocean or the battlefield; but then it was because the public mind was aroused and the public vigour put forth, though to the exhaustion of resources. There was a great general activity during the war, partly stimulated by the excitement of war, partly by successful commercial adventures connected with our supremacy on the ocean and monopoly of many branches of produce. We dwell upon these considerations because they appear, to some extent, to illustrate what has taken place under the Victorian era, when bold political reforms have enabled the fiscal fetters to be stricken off, and when the cheap bread of the people—notwithstanding any passing discontent—has been the safeguard against Luddite manifestations, and there has been made possible a financial extravagance in the State which has its parallel in the licentious luxury of the wealthier classes.

While drawing attention to these circumstances as affecting art, they must be understood in their relation to its material manifestations more than to its intellectual inspirations. The intellectual development of art is not solely or even mainly dependent on riches or the well-being of the commonwealth, though these latter conditions do favour the development of mental vigour. The production of genius, however, is not statistical; it is not a matter of averages, nor does it issue in any constant crop or fair series of harvests. Under the most favourable auspices it has its long periods of dulness and darkness, as well as long periods of brightness and brilliancy. Without resorting to literary history for examples, we may refer to that of the drama, because it is simpler and affected by fewer disturbing causes; indeed, from the commencement of the Elizabethan stage until now, in a period of three hundred years there has only been one violent action, that of the restriction during the time of the Commonwealth, but which was not long enough to destroy the traditions of the stage. We can, however, easily mark out several distinct epochs, marked by their several stars. This, however, is to be noted, that the inspiring and representative orders have not always been equally represented at the same conjuncture. Shakspeare and his brethren found actors to represent their plays, as did in France, Corneille, Racine, Moliere; but neither Kemble nor Kean had dramatists of their time equal to their effects. The consequence was they were thrown back for their chief triumphs on the Classic drama, but Burbage and his fellows worked with the living author, nay, for that matter played side by side with Shakspeare. Byron and Scott were willing to write for the stage, but could not supply Kean.

When the period for the revival of the drama comes we may rather hope for actors than dramatists. There is this to be observed in the comparison of the dramatic history of England and France, since the creation of a drama in the latter, that the schools of actors have been conformable in their brilliancy and their dulness: Garrick and Le Kain were contemporaries, Kemble, Kean, and Talma; and also that the school of comedy is better preserved in a period of decline than that of tragedy. In pictorial art we see likewise that in a time of dulness it is historical art that suffers, while genre and the naturalistic schools can be fairly preserved.

Bringing these experiences to bear on our progress in design, decoration, and architecture we can during the Victorian era witness a noticeable progress in the general well-being and national riches, in culture, and in material, but we are in no situation to determine what our future will be in what is really and truly architecture. It is questionable whether we have sufficient material to guide our criticisms in ascertaining what is the real influence of the contemporary and living mind on art. In the case of the drama it appears that when the actor has not the stimulus of the living dramatist in England and France, he is driven back on the study of the old or classic drama, which must be more imitative than inspirative. Not that Garrick did not create characters, but they were those from the inferior dramatists of the time, and his genius had not been able to give vitality to those delineations and to transmit them to our times. Most of the dramas of Garrick's days are dead to the stage. There must be something in the relation between architecture and the living popular mind. At the only time when architecture had a spontaneous vitality and development in this country, in the middle ages, there must have been a general harmony of sentiment in the cultured mind, and under such influence the Pointed styles continued their living career. When the Reformation came, the monasteries were shut up, and the schools of architecture and art were closed; so, too, was living architecture. The Elizabethan style was no development, but a decline, going through Jacobean, until at length there was a decided reflux under Inigo Jones, followed by Wren, to what was supposed to be Classic. This course has been followed to our own days, falling back upon the past, becoming more and more Athenian and Ionic, tightened in our leading strings. So far as what are called the Classic styles this is being relaxed for Italian, but the noteworthy feature undoubtedly is the falling back on what are called the national mediæval styles. We may, perhaps, trace the true beginning of this, not to Walpole, whose aspirations were distinctly Gothic, but to the later Georgian era, which gave a great expansion to Elizabethan, and this has been the true lead to Early English and the real styles of mediæval date. Now where is this to lead us? how far can we rule the career of art in the course of the human mind? or how far is the growth of the mind itself to lord it over the direction of art? This is all dim and obscure, and all that we can recognise is, as we have said, a great progress during the Victorian era in the materials for art, in workmanship, in the size, number, and variety of buildings, in the number of trained architects and skilled craftsmen; but the Victorian style we have not seen, nor do we know its semblance.

COLOURING SHOW DRAWINGS.—II.

WHEN the shading of the darker side of the surface is completed, the board should be turned round, and a very light tint of shading laid on at the extreme edge of the opposite side, thus making the lightest tint (or, rather, the uncoloured paper) to show, as already stated, at a position about midway between the centre and one side. In adopting this method of shading care must be taken that each coat is perfectly dry before its successor is laid on. The second mode, as applicable to small surfaces, consists in using the brush

as though it were a lead pencil. A thin wash is first laid on, as in the former method. When this is quite dry the artist takes a sable brush, goose-quill size and with a very fine point, and charges it with a very small quantity of rather strong tint by soaking it well in the colour, the greater part of which is then dried up with blotting paper. The artist proceeds to shade the object by line-touching it over again and again with the point of this brush. At first this will make the surface look rough and irregular in tint, and in going over it subsequently care must be taken to touch the parts missed at first. Thus the process must be continued, the work being gradually contrasted until the darkest line appears at its proper place on the surface. This is a very tedious process, but it has a beautiful effect when well done. The best general tint for shading is a mixture of Indian ink and Paine's grey, in the proportion of about three of the former to one of the latter. A very minute addition of carmine is sometimes advantageous, serving to warm the tint slightly.

Flat tints are sometimes very difficult, and cause much trouble, especially where the surface is much broken up and divided by other features in the picture, as, for example, in the front of a building which it is desired to colour of one uniform tint, but which is broken up by doors and windows. In such cases, before the wash is commenced, the artist must consider the picture attentively with a view of ascertaining (so to speak) the best route to follow with his brush. He should select that which is longest and narrowest, taking care to work on the length, as that will give him most command of his colour; unless, indeed, he finds this plan may break up his wash into too many parts, it being his first object to select such a line as will reduce these to the smallest number. If, too, he has to work round another object, whereby he will have to rejoin his starting point, he must search for a point where the joint will be as narrow as possible, and having commenced his work, to soften off the line he leaves at the outset, and working round to it again, to also soften off the finishing edge, and so "splice" the last tint over the first, which, if skilfully done, will leave no trace of joint whatever.

In preparing the colour for a flat, or, indeed, for any tint, care must be taken to provide an ample quantity at once, as it would prove ruinous to the appearance of the picture if when the surface was half completed the artist found it necessary to suspend his operations in order to grind more colour—ruinous because he would have a useless joint in the work, and also because, even with the utmost care, he would scarcely succeed in making his last tint precisely like the first, especially if it was a compound one.

In putting on flat tints in different planes adjacent to each other, and of uniform material, the tints should be slightly altered, both in colour and strength, in order to secure variety of appearance. This system may be worked out very successfully by using a particular tint in a variety of strengths for the different parts of a single casting; as, for example, in an ornamental piece of metal work having various flat fillets on it, the uniformity of colour would denote it to be one solid mass, while the variety of tints would impart a distinction of feature. In cases where the planes are features of separate details different colours must be used for each detail, each colour being treated according to the system described for one mass having variety of surface. This helps to convey the idea of a distinction of parts. There need be no difficulty in pursuing this system, because the skilful artist can always prepare a variety of tints of the same generic colour. For example, for cast iron a great number of colours can be mixed, all of the proper tint, but each having a very distinctive appearance. Paine's grey alone is excellent for cast iron; the addition of a little Indian ink alters its appearance, but preserves its character. Prussian blue and Indian ink in various proportions are also useful for the same purpose, as are numerous other combinations.

We cannot within the limits of an article like the present describe all the various expedients open to the artist to work up certain effects. We can only point out to him the direction; he must explore the road himself. For large washes of a tint to show wrought-iron work Prussian blue is an excellent colour; it must, however, be used very thin, as it is a difficult colour to "flat" well. Great care must be exercised in grinding it, as it is one of the most powerful and telling colours an artist can use, and the least trace in water will make a very strong tint indeed. The same property obtains when it is mixed with a different colour, which it will completely kill unless added in the most minute proportion. Cobalt is an excellent blue, and used alone makes a good tint for steel, while the addition of a little Paine's grey makes a very good wrought-iron tint; it "flats" beautifully. An excellent tint for yellow brickwork may be made from a combination of cadmium and raw umber, while for red bricks a mixture of carmine and burnt sienna answers well. Capital tints for woodwork can be had from combinations of Indian yellow, bistre, or raw ochre, and a trace of burnt sienna. Stone tints can be had from permanent or Chinese white, Indian ink, and the addition of a little red or yellow toneing tint. In "graining" woodwork it is best to execute the "graining" first, and then to wash on a "flat" of the same or a paler tint over all, the wash softening down the "graining" lines. When a number of planes come successively one within another at different distances from the eye, the one farthest off should be coloured first, each successive one being made a little paler than its predecessor, so that the one nearest the spectator is lightest of all, the darker ones behind thus serving to throw it forwards. The judicious use of shadow lines helps the general effect very much, but they should not be used to such an extent as in a plain line drawing, because they are sometimes apt to make a drawing look heavy. There are many points of this kind, on which the artist must exercise his own judgment, and his success will depend on his innate taste and industry. When the picture is completed the artist should look it over carefully for any omissions, and to ascertain if it needs any little touches to improve its appearance. It may be finally cleaned down with bread in the usual manner.

THE *ATHENÆUM*, CUT GLASS, AND PURITY IN ART.

THE *Athenæum*, in devoting an article lately to Mr. C. L. Eastlake's "Hints on Household Taste in Furniture, Upholstery, and other Details,"* has given us an authoritative dissertation on taste in matters of art. As this will receive some attention it is desirable to advert to its doctrines, which are not simply based on those of Mr. Eastlake, but which are those of the writer himself, and is in continuation of his observations on the furniture of the Great Exhibition of 1862. He laments, naturally, not only the want of common taste, but of common sense, in the tradesmen engaged in the supply of all kinds of furniture. Upon the details of this well-grounded complaint we will not dwell. We concur with him as to the very limited results obtained from the expenditure of hundreds of thousands of pounds on thousands of pupils for art education. On entering upon particulars of want of taste his chief grievance seems strangely enough to be cut glass. Cut glass, whether in the shape of table glass and its cognates, or of chandeliers or gaseliers, he looks upon as an abomination. He calls it eye-torturing cut glass, the results of wasted labour, and a material made to belie itself. He considers it too base even for the theatre, and is barely satisfied with its being relegated to the gin palace. His objections to it are manifold, and though not set out in array, we can discern them. One is that cut glass gives forth "prismatic hues," and we suppose in that respect is eye-torturing. Another is, as we have just intimated, that cut glass is a sham, and a material made to belie itself. In what respect this can be it is very hard to make out. It is an unfortunate optical property of cut glass and prisms to give forth these "prismatic hues," a *lèse majesté* against the purity of white light, of which nature has had the audacity to set the example, and by which science has profited. We make out, too, there must be some moral unfitness in cut glass which disqualifies it for genteel company—by implication, churches and fashionable dinner parties; which renders it questionable in immoral resorts—as theatres, dancing rooms, and music halls; and which places it beyond question in localities where it cannot offend morality, religion, refined taste, or silver forks, namely, in gin palaces.

One shape of the abomination is in dinner services and the like, but we conceive that this can scarcely be the capital offence, though amounting to a very severe form of eye-torturing. A cut glass decanter on a dinner table must certainly bear with it its own condemnation, that of the wine it contains, and that of the Amphitrion or rather hostess who can offend friends and art critics by such a disgusting exhibition. In its way it must be almost as bad as eating fish with a knife when forks are in fashion, if not worse; or eating fish with a fork when knives and forks are in fashion and not using the knife. The capital offence may be committed at night or in summer time, when the shutters are closed by the above-named criminal, in lighting gas or wax tapers in a cut-glass chandelier or gaselier. This results in eye-torturing by bringing out prismatic hues, and would, we should fancy, cause an accomplished art critic at once to absquatulate, or pass some severer censure. We believe, but may be unjust to the writer in suggesting it, that one great reason against cut glass gaseliers is that they were not used by the Athenians in the purity of their art when they erected the Parthenon, nor even by the architects of the Middle Ages.

A part of the affliction of the writer in the *Athenæum* is due to his hearing and reading the outpourings of admiration of self-styled art critics, or, as he dubs them, amateur art critics, at the cut glass in the Paris Exhibition. "Flashy," says he, "as the prisms they desired, and ignorant of the common taste, some of our easy-going guides rose to ecstasy about the exploded mode of using double and homogeneous glass, as if it had been angular, intractable, and glittering crystal." The public will learn from this what constitutes an amateur critic, and what constitutes a professional critic. There is, however, some cream of comfort for the latter, that the public taste is declaring against cut glass, though he rationally doubts whether this is due to any improvement in the public taste, or only to some change of whim. He thinks it is only true critics and men of taste who have given in their adhesion to plain glass against cut glass. However, he avails himself of the relief such as it is, and he particularly congratulates himself on the partial discomfiture of a terrible bugbear, the costly gaselier at the Haymarket. "That gorgeous fountain of prismatic hues and wonder of the Regency, every tint of which tortured the educated eye, has been hoisted up higher than ever in the roof"—as we strongly suspect by the influence of the art critic of the *Athenæum*—and he further threatens that "its next move will surely be out of sight to the limbo of great gewgaws, wherever that may be." His denunciations of its fate do not end with this. "This magnificent offence may, let us hope, glorify,

* Reviewed by us at page 811.

in years to come, the biggest hut of some Gold Coast potentate, or 'drop' by 'drop' flash from the nostrils or the earlobes of a thousand of fair Polynesians."

It is rather dangerous after such denunciations to speak of cut glass; but, although cut glass is guilty of prismatic hues, we very respectfully suggest, for the opinion of the tribunal, that there are other eye-torturing criminals, encouraged by the high, vulgar, and the low, as yet unconvicted. Waterfalls and cascades are sinful in prismatic hues, and Niagara is a monstrous offender. Fountains are artificial, and, we suppose, sham exponents of the same vices. The rainbow is a culprit, and there are waterfalls and fountains notoriously addicted to the display of rainbows. This constitutes a double offence. We can almost let off a deplorable seducer of the innocent and ignorant—the fountain with the rainbow—which the French have persisted in upholding. Whether rainbows and waterfalls can be put down is uncertain in the present state of our jurisdiction. But fountains can; the water they misapply can be cut off, and a special act of legislature will abolish the great mistake of fountain days at the Crystal Palace.

Stained glass, which mediævalists admire and seek to extend, comes under each head of the indictment, and poets have been capable of admiring the prismatic images cast on the marble pavements of cathedrals. The Puritans, in suppressing such abominations, were purer critics in art than they have had credit for.

As to the future of art, we look upon it that waterfalls, cut glass decanters, rainbows, chandeliers, gaseliers, fountains, and stained windows may be looked upon as virtually abolished.

ARCHITECTURAL ALLIANCE.

REPORT OF THE DELEGATES FROM THE ARCHITECTURAL ASSOCIATION ON ARCHITECTURAL EDUCATION.*

HEAD II.—THE BEST SYSTEM OF ARCHITECTURAL EDUCATION TO BE EMPLOYED IN ENGLAND.†

IN the scheme of architectural education which we now set forth *as suggestive only* of what might be done, it must be remembered that we are far from being able to realise its establishment at present. It may take twenty, thirty, or forty years to bring it into existence. [*At all events there is no reason why we should not at once lay down a programme of the most complete scheme in order to form an ideal towards the formation of which we must continually exert ourselves.*] That some day such a system will be rendered necessary as is now just starting in America under the auspices of Professor Ware, and as that which has flourished for the last century in France and Germany, will, we think, be patent to all. Special architectural schools must be formed in various parts of the metropolis, and in all the principal towns situated in the centre of the habitable portions of the country, all being indirectly under the supervision of a central university, in which would be invested the power of holding examinations and granting degrees, and the offering of various honorary prizes for competition. The universities would be supported by government and by endowments, as other universities, the direction, however, resting entirely with the profession; and it is probable, at first, that governmental aid would have to be given to the school [*but they should eventually be self-supporting, and we firmly believe that the large sums spent annually in premiums would be of themselves sufficient to pay the expenses of any schools.*] The course of study should be for three years, and a slight examination in classics, mathematics, history, and drawing would precede the admission of any student. Examinations also in the scientific subjects taught would be established, to test, from time to time, the knowledge of students, and to give them a point to work up to.

* Concluded from page 824.

† Mr. J. Douglass Mathews signs the report, reserving his opinion, however, as to the whole subject-matter of this head, and the report is signed by Mr. Rickman with reserve as to those passages included within brackets ([]) and asterisks (*) under this head and under Head IV.

COURSES OF STUDY.

First year.—Freehand drawing from the round and from the antique; geometrical and architectural drawing and shading; the theory of the elementary part of mathematics, including descriptive geometry; elementary mechanics; elements of design, plans, sections, and elevation; elements of construction, framing of trusses in roofs, &c.; history of architecture.

Second year.—Drawing from the antique and the life; perspective; applied mathematics; descriptive geometry applied to stone building; carpentry; mechanics and physics; geology; design and construction; surveying; history of architecture.

Third year.—Design and construction; specifications; supply of water; ventilation; acoustics; principles of estimating; the strength of materials; architectural jurisprudence; surveying and leveling; practical geology; materials.

Throughout the whole course, the student would have to produce at intervals of a fortnight or a month, a sketch design—in the first year copied more or less from existing examples, and in the second and third years (in addition), every two or three months, a composition (plan, section, elevation, and perspective)—of some building, which would all be submitted at the central university, so that the several schools in London and the provinces would be brought into competition or for medals and prizes. At the end of the third year, if the student passed a fair examination, he would be required to pass two whole years in the office of some architect, working out practically what, more or less theoretically, he had acquired in the school. A portion of this two years might well be spent as assistant clerk of works to some building on the drawings for which he had previously been working. At the end of the two years he would be expected to pass a final examination, which would qualify him for architectural practice, though a strong recommendation would be held out (and here travelling studentships would come into use) to spend six months or more in travelling. In the school nine months only in the year would be occupied by lectures and other courses, and during one month at least of the three months' vacation, the student would be expected to draw and measure old work, and submit the same to the universities, where prizes for the best series would be offered.

HEAD III.—THE OPPORTUNITIES WHICH ACTUALLY EXIST FOR EXTENDING THE SPHERE OF ARCHITECTURAL EDUCATION.

The facilities for architectural education now afforded in London are:—

King's College.—The courses of lectures in the Applied Science Department, intended for civil and mechanical engineers, but which in many cases have been followed by architects. The main course extends over two years, and comprises mathematics and descriptive geometry; chemistry, physics, and mechanics; machinery and manufacturing art; mineralogy and geology; surveying and levelling; architectural and freehand drawing; the workshop; and, lastly, Professor Kerr's lectures on "The Arts of Construction." Evening courses (6—8), mechanics, mathematics, and drawing.

University College.—Mathematics, descriptive geometry, physics, mechanics, chemistry, mineralogy and geology, engineering, surveying, and levelling, mechanical and freehand drawing, and architecture and construction, by Professor Hayter Lewis (this latter an evening class). There are also evening classes here in mineralogy, geology, engineering, mechanics and physics, mathematics, descriptive geometry, and projection of shadows. The schools at

South Kensington are more especially intended for the instruction of art teachers who have to obtain certificates qualifying them to superintend the various art schools disseminated throughout the country. Any instruction, therefore, obtained there can only be partial as far as architecture goes. There are, however, ample opportunities for beginners, to wit:—Classes for freehand drawing and drawing from the antique and the life; class of elementary architectural drawing, of descriptive geometry and the projection of shadows. In the museum is a collection of architectural casts, models of roofs of buildings, and architectural drawings; and there is a most valuable art library, open to the student at all hours. In the evening all the drawing classes are open. In connection with South Kensington are various art schools in London and the provinces, where freehand and other drawing can be learnt, both in the day time and in the evening. There are also private schools, as Heatherly's, in Newman-street, &c. At

The Royal School of Mines, Jermyn street, there are lectures on physics and geology which can be attended by occasional students on certain conditions, and courses of instruction in mechanical drawing and descriptive geometry. In the evening at certain times in the year are courses of eight lectures on physics and eight on chemistry; intended for those in training at South Kensington as art teachers. These can be attended by students for 5s. each course.

The Royal Academy demands a test of efficiency from all before admittance there as students; the test being a design for some building to be made in twelve days in the academy. They give a course of forty lectures in perspective and scenography or the projection of shadows; and four lectures in each of the following subjects—Architecture, painting, sculpture, and anatomy. They offer for competition among the students—A silver medal for perspective drawing and scenography, a silver medal for a measured drawing of some existing building; a gold medal for an architectural design; and a travelling studentship for one year of £100, for a design executed in one month in the academy. There is also a library open at certain hours, and a valuable collection of casts.

The Royal Institute of British Architects offers this year:—A silver medal for an essay; a special prize of £10 for an essay "On the Application of Moulded and Shaped Bricks to Architectural Purposes;" the Soane medallion and £50 (under certain conditions); a prize of £10 10s. for a design for a Gothic theatre; a prize of £12 for an Italian design; a silver medal for measured drawings; two student's prizes—one for designs, the other for drawings of ornamental details; and the Pugin travelling studentship, value about £100. They hold a voluntary architectural examination on those subjects with which every architect must be conversant. They have a most valuable library, open to fellows, associates, students, and to those who are preparing for examination gratuitously; and lectures are given or papers read on various subjects connected with the profession.

The Architectural Association offers this year two prizes in the Class of Design; one in the Class of Construction and Practice; one for an essay; one in the Figure Drawing Class; a prize of £5 for an architectural design; two prizes for measured drawings; a prize for designs for cottage stoves; and a prize (offered by the Sketch Book Committee) of £5, for a title-page; and they publish a valuable and useful sketchbook. There are open to all members:—Classes for design; construction; figure drawing, landscape drawing and colouring; a circulating library, rich in quality if not in quantity; and at ordinary meetings a series of interesting papers connected with the profession.

The Architectural Museum, the new premises of which are now nearly complete, possesses a most valuable collection of mediæval casts in a large room for students, where they can be drawn. The library of

The British Museum, unfortunately open only in the daytime, is easily accessible, and contains every publication known. At

The Crystal Palace there is an extremely valuable collection of casts which might be studied and drawn from to great advantage by those living in the vicinity.

HEAD IV.—MODIFICATIONS AND ADDITIONS TO THE CLASSES, ETC., SET FORTH UNDER HEAD III, AND SUGGESTIONS FOR PROVISIONAL SCHEME.*

Before entering into the question of how far the institutions referred to under Head III. could be modified or added to, it will be advisable to suggest a method by which they can at the present moment be utilised to a greater or less degree. To do this we must class our suggestions into three divisions—Firstly, for those who are not yet articled; secondly, for those who are at present articled or are in any office as improvers; and thirdly, for those who have passed through their articles and are now paid clerks. For the first class in the absence of the central University or school suggested under Head II., as it is more or less necessary that the student should have the advice of some architect as to the exact course of study he should pursue, it would be well if he were articled under these two conditions:—

* Mr. J. Douglass Mathews reserves his opinions as to Head IV., with the exception of that portion enclosed within brackets ([]) and daggers (†), with which passage he thoroughly agrees

Firstly, that it should be for five years; secondly, that in the first two years he should follow out a complete course of instruction at King's or University colleges [*(in the daytime of course), and that his spare time should be spent either in the office of the principal or in some room specially provided for that purpose. In large offices where the number of pupils is considerable (say above 5) and the premium £150 or more, it seems to us that it would be but right that, if the principal had no time himself, he should have a regularly paid instructor, who should superintend the pupils and give them advice. In smaller offices this advice must necessarily come from the principal. But there is this great and important principle to be laid down, "That when a pupil enters an office and pays a premium he has a right to be taught, and it is a grave injustice towards the pupil and his parents to make him do nothing but the work of paid clerks under the pretence that he is learning by it;" in other words, the architect has no right to look upon premiums as a quiet sinecure in consequence of his position, and for which no return on his part is required, except the permission to work on his drawings.*] At the end of the second year the pupil would be able to enter into the regular routine of office work with advantage to himself and to his principal. Even then his individuality should not be lost sight of, but on one or two days in the week he should be allowed to work on his own designs and drawings, which might be destined for the competition prizes of the Academy, the Institute, or the Association. It would be of immense advantage also if, in the last year, he could be sent for three months or more out on some building as assistant clerk of works, because he could there carry on the same work as in the office, and be able to see it all actually carried out. In the last year of his articleship also he should turn his attention (and here evening work will perhaps be necessary) to the subjects asked for in the Voluntary Examination, and this test of ability should follow at the close of his articleship, and according as he had made good use of his time he would be able to go in for proficiency or distinction. A short tour of at least six months should then be made in England or on the continent, and we cannot insist too much on this very important feature of an architect's education—one in which there is a great falling-off at the present day, although the facilities for travelling have been so much increased. [*In no case ought a vacation of less than six weeks to be given,*] and it should be a *sine qua non* that a large part of all vacations should be spent in the delineation of ancient buildings to be submitted to the principal on the return of the pupil to the office. In the second division, those who are already articled, or who are improvers, are to a certain extent already tied down to perform certain duties in the office. We can only, therefore, recommend that they should try and obtain two mornings a week to be occupied in drawing at South Kensington, in one of the local schools, or in the Architectural Museum (when open), and that their evenings, and as much more time as they can obtain in the daytime, should be devoted (1) to the preparation of designs for the Class of Design here or other competitions in the architectural societies; (2) the measuring and drawing, during the summer months, of such ancient buildings as are in or near London, and in the winter measuring and drawing in the Museum at South Kensington or in the British Museum; and (3) attendance at lectures at King's and University Colleges in physics and mechanics, and, more especially, those on architecture and construction by Professor Hayter Lewis, and on arts of construction by Professor Kerr, and those at the Jermyn-street Museum on physics and chemistry. [† For these and all other students it is a point of great importance to test their knowledge at certain intervals, and we believe that the establishment of examinations on various subjects from time to time here in the Association would prove to be of great value, the whole to tend towards the eventual passing of the voluntary architectural examination. The suggestion offered in the first division about going out of the office as assistant clerk of works applies equally here. Above all, we cannot impress too strongly upon all students the importance of reading good professional books continually. The man who, dictionary in hand, goes carefully through the article on "Construction" in "Viollet le Duc," will learn more and will get more good principles in his head than all the lectures in the world can ever teach or give him.†] The third division, paid clerks, we may assume, have only their evenings wherein they can practice any additional architectural studies. The evening classes at King's and University colleges, and at the Jermyn-street Museum, offer instruction in physics and mathematics; the Kensington schools and local schools in drawing from models, and from the antique and life; and our Association in design, in practical construction, and in various subjects akin to architectural study.

We have now to consider as briefly as possible wherein all the institutions named could be modified or added to for the improvement of architectural education.

At University College a great scheme is in course of preparation originated by and under the auspices of (as far as our profession is concerned) Professor Hayter Lewis. We are not prepared to give yet any idea of its development, beyond that it aims at the establishment of an art university which, coupled with the science training already given, will make the course of instruction there more or less complete.

At King's College within the last four years, freehand and architectural drawing has been taught in addition to other subjects. As yet 2 out of 60 only of the students of the applied science department became architects; a greater supply of them would of course tend more to the encouragement of the two subjects named above. The course of lectures on machinery and manufacturing art could be replaced by a course of lectures on the history of architecture. Levelling might be taught with surveying in the second year, and, in "the workshop," more especial attention given to the construction of roofs, scarfing of timbers, carpenter's work, and joinery. An evening course of Professor Kerr's lectures on construction might also be given.

At South Kensington a special room might be found for an architectural studio, where architectural drawing and shading might be varied by measuring and drawing the many architectural casts of doorways, pulpits, and the building models, etc., copying the numerous architectural drawings there, and also in working out designs.

The choice between South Kensington, King's and and University Colleges, must depend somewhat on the talents of the pupil. If he has been instructed in science and mathematics, let him go to South Kensington; if he can draw well, let him go to one of the colleges; if neither, and his health or disposition puts evening work out of the question, he had better go to both in succession.

In the Royal Academy, as yet, architectural students are not encouraged to enter into the antique school, because, being necessarily very much wanting in that power of drawing and shading possessed by painters and sculptors, they would tend to lower the standard of excellence. But in its new premises the Academy might (and we have good authority for believing that they will) set apart a special room for architects in which the finest collection of Renaissance ornament casts in London could be placed, and where architectural pupils might learn architectural drawing and drawing from the antique. The silver medal for measured drawing should be given not only for Renaissance, but for Gothic subjects, and there is no reason why portions of Westminster Abbey should not be asked for in the programme as well as St. Paul's and other Renaissance buildings. The gold medal might in the case of those students who, living in the provinces, cannot follow the evening course of lectures (which extends over four months) be thrown open to them without the necessary attendance at lectures on condition of their passing an examination in perspective. The travelling studentship of £100 is not sufficiently competed for, the probable reasons being (1) that it would cost more than £100 to travel for one year (and its possessor would therefore be much out of pocket), and (2) because the winter is exceedingly unfavourable for outdoor drawing, even in the sunny south of Italy. Now, from the 1st of March to the 1st of December (9 months) would give the student ample opportunities of profiting by his travels, the expenses of which would, with economy, be covered by the above sum. On the return of the student his drawings should be exhibited publicly to the other students, to show the advantages he has derived and to excite an interest in them to do the like. A silver medal for drawings from the antique, open only to architectural students, might well be accorded.

The Royal Institute of British Architects, it must be remembered, derives its income from voluntary sources only. It has, therefore, not the means of establishing any great scheme of architectural education; but there is a very great deal it might do if it would only take up the question in a truly liberal spirit. In the first place, it might give its support to the opinions expressed in this report. Secondly, as its rooms are used only once a fortnight, it might establish courses of lectures on the various subjects set forth in its examination scheme, the fees of which should be paid half by the Institute and half by the student [*or, if articled, by his principal*]. To those students attending these courses the library should be thrown open, books pointed out to them, and small examinations at fixed time should be passed. The subjects of these lectures in some cases might be elementary, in other cases on the more practical points of the profession. Thirdly, the Institute might secure the exhibition room at Conduit street and found in it an architectural studio, under the supervision of visitors, as at the Academy, and as in the schools at Paris, Vienna, and elsewhere.

The Architectural Association, having just taken additional rooms at Conduit-street, has the power of adding still more to the advantages which it now offers. Firstly, in forming a junior class of design, in which the students should be advised to copy old and good architectural forms rather than originate bad ones; in which small subjects should be given to be worked out with details in the Early English, Decorated, Perpendicular, or French styles; and, for the Classic student, adaptations of the orders of Vitruvius, Palladio, Serlio, and others; books being pointed out to the members, as also where they could best obtain their information; and direct but intelligent copying should be specially asked for. Secondly, on another evening of the week the economy of construction might be gone into, and a complete design for a small house, church, or school worked out, with specification, details, &c. Thirdly, on another evening short papers on various subjects connected with the profession (such as ventilation, acoustics, geology, building materials, &c.), might be read, all students taking notes. Fourthly, drawing from copies and casts, of ornament, and architectural drawing might be carried on during other evenings in the week. The Association might also procure drawings of ornament and architectural drawings to be lent out to copy on similar conditions as the books in the library.

The Architectural Museum in Westminster will shortly be open, and there will be rooms for students in which the composition of ornament might be taught in conjunction with drawing old work; the larger casts also of sedilia, doorways, &c, might be carefully measured and drawn to scale.

In conclusion, we have to apologise for the length of the report—a length necessitated by the numerous considerations which so wide a subject demands; and we believe that we have adopted the best course by first laying down, with all their advantages and disadvantages, the courses of instruction which exist here and abroad at the present day, and on these (as our basis) suggesting the establishment of a scheme which will be beneficial alike to architect and pupil.

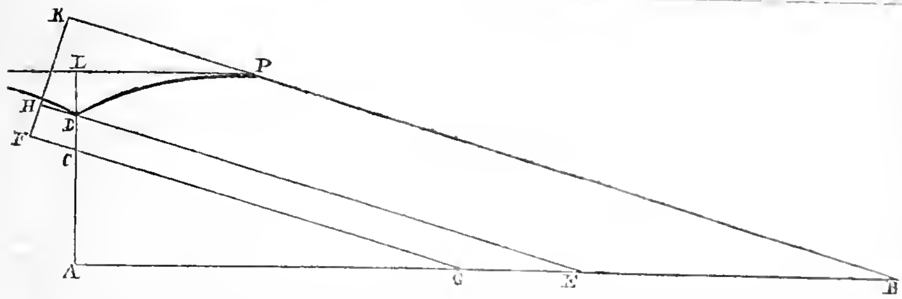
SOUNDING BOARDS.

THE Rev. S. S. Greatheed, of Corringham Rectory, Essex, has sent a letter on this subject to the *Ecclesiologist*. He says: Let us consider what conditions a sounding-board should fulfil. First, it ought to intercept those portions of the waves of sound which would otherwise ascend to the roof of the church, and, when reflected thence, produce a resonance that would make the preacher less audible, in consequence of the path of the reflected wave being much longer than that of the direct wave. Secondly, the part of the wave intercepted from passing to the roof ought to be reflected in a direction where it will be of use—namely, towards the more distant portions of the congregation. Lastly, the sounding-board should be impartial in its distribution of the sound, and not send it all in one direction. Now, the flat sounding-board fulfils the first condition, but not the second. The Blackburn parabolic sounding-board fulfils the first and second conditions, but not the third. I am confident, however, that



sounding-boards might easily be made in a form that will satisfy all the conditions; and the accompanying plan will enable architects and others to judge whether this form is not also the most elegant that has been yet proposed. It is generated by the revolution of a parabolic arc round a vertical axis passing through its focus, and inclined at an angle rather greater than 90 deg. to the geometrical axis of the curve. Since, however, an exact solid of revolution would not be easy to construct on the required scale, I recommend making the horizontal sections octagonal instead of circles. This will both render the construction easier and improve the appearance of the thing: for it will then be similar to a pendent from a vaulted roof. The sharp point, which might seem to threaten the head of the preacher, had better be cut off, and replaced by an ornamental boss, as the loss of a few inches of reflecting surface in this part of the board is of no consequence.

I proceed to show how working drawings of a sounding-board of this kind can be made out. A B is a horizontal line about 4ft. from the floor of the church, drawn in the direction in which the preacher is to face, representing the average level of the ears of the congregation; C a point a little in front of the mouth of the preacher; D about 18in. above C. Determine the point E in A B, where the effect of the sounding-board begins to be wanted; join D E, and through C draw F C G parallel to D E; produce E D to H, and make D H equal to C D: draw H F perpendicular to F G, and produce F H: through K, a point taken in this line, draw K P parallel to C G: then, if C P and K P are equal, P is a point in a parabola whose focus is C, and axis is C G. Let us suppose B to be the furthest point to which the preacher's voice, aided by the sounding-board, can reach In some cases this may fall short of the western wall of the church; but whether it does so or not can only be determined by experience. Then, if K P produced meets the horizontal line in B, P is the limit to which the sounding-board need extend. The other points in the curve, between D and P, will be determined by making the distance from C equal to the perpendicular distance from F K. If P L be a horizontal line meeting A D produced in L, P L will be the semidiameter of the sounding-board.

The figure has been drawn with regard to distinctness, rather than to the proportions which are likely to occur in practice, and, therefore, the sounding-board seems very broad. Supposing the octagonal form to be chosen, it will be convenient to determine the shape of the ribs first. Each rib will be a parabola, which may be determined by increasing L P and all similar lines in the proportion of the radius of the circle circumscribing an octagon to that of the inscribed circle. The spaces between the ribs may be filled with thin pine boarding. An ornamental moulding can be placed round the edge of the sounding-board; but it should not descend below the parabolic surface. The back part of the sounding-board will, of course, be intercepted by the wall or pier against which the pulpit stands. A bracket can be placed here to help to support the sounding-board. When finished, the parabolic surface should be coated with varnish that will dry hard.

SCIENTIFIC HOUSE BUILDING.

PROFESSOR ROLLESTON, M.D., F.R.S., of Oxford, in a communication to the *Lancet*, has called attention to certain important points which the study of recent sanitary literature and of practical house-building has pressed upon his attention. Firstly, it seems to be clearly made out that the interposition of a layer of impervious substance, of whatever kind so that it be impervious, between the level of the *ground water* in the soil and the floor of the house built upon it, confers upon such a house an immunity in cholera epidemics. Facts in support of the truth of this statement are contained in a recent paper published by Professor Pfeiffer, and Dr. Rolleston is of opinion that the indication they afford should lead us to extend over the entire area occupied by a house the same layer of impervious material which is put into the walls as the so-called "damp course." Such a superficial stratum may be cheaply made by a mixture of gravel and gas tar. It would effectually prevent that rising of watery vapour out of the soil which the "aspiring" effect of a warm house does much to intensify over the area it covers. This aspiring effect can be observed to advantage in rooms constructed by a certain school of architects, who by combining modern appliances with mediæval style, have contrived to combine also the maximum expense with the minimum of comfort. In such apartments the doors and windows fit closely; ventilation is, of course, ignored, because in the middle ages the scarcity of glass and its supplementation by lattices, rendered ventilating appliances needless. The fire, however, must be fed from some source or other, and in such rooms a surging movement in the carpet may be noted, showing that the fire is drawing its supply of air through the chinks in the floor and from the damp air beneath; and this must be the case in all warm houses unless an easy access of external air is allowed, otherwise their rooms must be acting, says Dr Rolleston, constantly upon the air in the soil they cover in the fashion of imperfectly exhausted receivers; and that what they thus draw up must be more or less insalubrious needs little argument. To prevent all this Sheringham's valves, on a level with the ceiling, and a layer of asphalte on the earth below the floor is recommended, the outer air having free access to the space between the asphalte layer and the floor. Dr. Rolleston refers further to the necessity for removing the subsoil dampness as a preventive of consumption, as shown by the researches of Drs. Bowditch and Buchanan; and he remarks that there is some little difficulty in reconciling its attainment with the adoption of the present system of sewage drainage, by which the rainfall is excluded, but notes that at Lubeck the ends of sewerage and drainage have been secured by surrounding the drain pipes with a layer of gravel, and thus the old "stone drain" of English agriculture has been economically revived, and the same excavation which lodges the impermeable and small-calibred drain pipe of modern sewerage serves also, by receiving stone and gravel, to dry a water-logged soil.

TREES IN THEIR ORNAMENTAL ASPECT.

TREES, to be seen, must be planted in groups, not in files; and to be ornamental they must be well grown. It is not easy to spoil a country with green leaves, especially when it is undulating, but a great deal is done in that direction by rows of hedge timber, which confine the view and present to the eye a succession of sharp angles and narrow squares, instead of bold, sweeping lines with breadth and extent. Even an avenue, says the *Agricultural Gazette*, though a noble object in itself, is often destructive of the landscape, which is hidden by it as effectually as it would be by a brick wall. We do not advocate any stripping of the country of the trees and foliage, which are its greatest charm, but we would have handsome trees in the right place. Everyone loves trees, and we are only recommending a reasonable instead of an inconsiderate affection. Landed proprietors might relieve their estates of the great and unsightly incubus of fence timber, and increase their profit by judicious planting. There are more arguments for than against indulging a harmless hobby, and this would be a very interesting and useful one. Whether we speak of a large estate or of a small farm, its embellishment with [illegible] and trees requires a little of the landscape gardener's art, both in planting and in cutting through the formal hedgerows. If this latter process is done properly, a novice will be surprised to find, when he has removed half his timber, that there remains, apparently, more than before. It is literally a case of eating your cake, and yet having it. The fact is, by breaking through the rows distant trees are brought into sight, and the eye thus takes in a greater number at once. This is a great advantage of clumps and groups over straight lines; moreover, the sight wanders among them without coming to a full stop as against a wall or a hedgerow. The waving outlines and the appearance of distant objects in varying lights and shades [illegible] ness and [illegible] pleasing in a landscape, and which add very much to its apparent extent. The main things to attend to in planting for ornament are to plant the salient points—that is, the highest and most prominent spots, and to plant bold groups not too near together.

ARCHITECTURAL SOCIETIES.

EDINBURGH ARCHITECTURAL ASSOCIATION.—The usual fortnightly meeting of this association was held on Wednesday, December 3, in the hall, 5, St. Andrew-square, Mr. A. Ballantine, president, in the chair. The preliminary business having been disposed of, and several new members elected, the first of a series of three papers was read by Mr. F. C. Sumichrast-Roussy, entitled "The Comparative Merits, Beauties, and Characteristics of Grecian and Mediæval Architecture." Mr. Roussy made a few preliminary remarks on the various causes originating architecture, showing the influence of climate and locality in developing certain forms of designs, and continued by a very highly instructive treatise on the peculiar beauties of the arts amongst the Grecians. The paper was concluded with an analysis of the elements of the beautiful, which he divided into three heads, discussing each separately in a very successful manner. The librarian intimated the names of several new books just added to the library, and also a series of photographs of the Craigentinny Monument, presented by Mr. Campbell, photographer. A hearty vote of thanks to the lecturer closed the proceedings.

LEICESTERSHIRE ARCHITECTURAL AND ARCHÆOLOGICAL SOCIETY.—A meeting of this society was held in the Town Library, Guildhall, Leicester, on Monday week, G. C. Neale, Esq., in the chair. After the transaction of business in committee, Mr. Thomas Barnard, of Botcheston, was elected a member of the society. Mr. Weatherhead exhibited an example of red ware (known as Samian ware), interesting as bearing the impress of the potter's stamp, MFERNIM, found in Leicester, presented to the museum by G. H. Nevinson, Esq.; also a curious bronze seal, discovered November, 1868, in soil removed from the Cherry Orchard to Evington-street, presented to the museum by O. C. Broomhead, Esq.

SCHOOLS OF ART.

THE annual meeting of the York school of art was held in that city on Tuesday week, the Dean of York presiding. The report which was read showed considerable improvement during the past year both in the number of students and their progress. Several gentlemen having addressed the meeting the prizes were distributed by the Dean, to whom a vote of thanks was then most cordially passed for his courtesy in the chair.

The annual dist[illegible] of prizes of the Trowbridge school of art took place on Wednesday, the 2nd inst. The principal prizeholders were [illegible] Webber, [illegible] Wilkins, E. L. Phelps, [illegible] Taylor, G. [illegible]well, Messrs. C. H. Ryles, [illegible] F. H. Pardt, G. White, Fred. Bullen, and Mr. A. [illegible]

The Liverpool Corporation has sustained a severe loss by the death of Mr. Thomas Duncan, who for many years past had filled the office of engineer to the Liverpool Waterworks. Mr. Duncan entered the corporate service about the year 1844, and until his health broke down some months ago, he was constantly and laboriously devoted to the public service. He died early on Friday morning last, at Leamington, of an internal affection which has troubled him for some time having culminated in dropsy.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

MOSAIC DECORATION.

AT the conclusion of Mr. Layard's paper, a sommary of which appeared in our last impression, a lengthy discussion ensued.

Mr. DIGBY WYATT said that twenty years ago he stated publicly in that room that he saw no reason why we in this country should not do all that the ancients did in the matter of mosaic. That we had got so far hitherto was very gratifying, but much remained to be done, and much rested with the architect. Although we had plenty of mosaic workers and plenty of mosaic fit for our buildings, it was a question whether we had buildings fit for mosaic. The use of mosaic in this country seemed to be very much associated with the development and use of brickwork. Brick was the natural material for our use, besides being economical. If we were to have structures in which we had arches and vaults of brickwork, money might be saved which could be employed in decorating with mosaic the surfaces at present left blank. It was essential for architects to make up their minds, before beginning a structure, what its decoration was to be, so that the decoration might ally itself with the architecture, instead of being stuck on to a structure, and thus preventing an homogeneous appearance. While the progress made by Mr. Salviati was highly gratifying, it was extremely satisfactory to see the efforts which had been made by intelligent workers in England. Mr. Rust had been very successful in most of his specimens, and the manufactures of Messrs. Powell, of Whitefriars, were much to be commended. No one tradesman could supply the wants of the civilised world in this matter. In anything which delighted the eye the more that was done the better. Alluding to the recent introduction of enamelled iron, Mr. Wyatt said that it was a material which only required the application of a little taste and a little judgment to become an element of external decoration most valuable to the architects of the future. A point requiring great attention was the selection of the cement for fixing mosaics. If a quickly-drying plaster was used, rain from the outside would be drawn through the interstices by capillary attraction. If, after the cement was dry, the whole surface of the mosaic could be floated all over with oil or some other substance which would fill up the crevices, a really waterproof joint would be arrived at, thus ensuring the protection from damp not only of the mosaic, but of the wall of the building. In conclusion, he proposed a vote of thanks to Mr. Layard for his paper.

Mr. STREET, in seconding the proposition, expressed his almost complete agreement with Mr. Layard's opinions, although he thought that distemper paintings could still be employed with advantage in many situations. While the idea that the ornamentation of a building should form an integral part of its architecture was essentially correct, it would be impossible to think, in most cases, of covering all the walls of a structure at once. Dr. Salviati's material seemed to him (Mr. Street) to be the best. The only doubt was whether the cubes of gold were not larger than those in Venetian work. Some years ago, when at Torcello, he measured the cubes in some mosaic work which was being mutilated, and found them to be not more than three-eighths of an inch square. In designing figures in mosaic it would be well to have excessively clear outside lines, and as little shading as possible, using strong, well-defined lines for shadows. Mosaic decoration was peculiarly adapted for backgrounds to bas-reliefs.

Mr. AITCHISON said that he hoped shortly to see some small building decorated in a perfect and complete manner throughout with mosaic. It was of the greatest importance that coloured decoration should be of an oriental character. He thought that the gold ground particularly afforded facilities for ecclesiastical decoration. The true effect of the gold ground in Italian work was not that of a glittering surface, a neutral greyish green colour being presented. The ancient work invariably exhibited this tint, while modern work had more the appearance of the surface of a brazen vessel. On a close examination of some ancient work at a great distance from the ground, he found that it was executed by means of very long slips of mosaic put into the plaster when wet and left entirely detached, so that there was a shadow all round, which took off the glitter spoken of. When plaster was put flush with the surfaces of the tesseræ the effect was that of a large mass of glittering gold, which was very unpleasant. The pieces used by the ancients, though small, were apparently cut with a hammer, so that an irregularity of surface and edge was presented, and plaster was plentifully used, the picture being about two-thirds mosaic and one-third plaster. We had a large number of distinguished architects who would be extremely glad to give a great deal of their time almost gratuitously to design figures for execution in mosaic in our large public buildings. Many of these distinguished architects would, he was quite certain, be ready to assist with suggestions, and even perhaps with designs, the younger members of the profession. As in stained glass so in mosaic, white was to be used with a most sparing hand. He did not know what the effect of a building wholly covered with mosaic would be, but, judging from the effect of stained glass in the completely gilded building of the Sainte Chapelle, at Paris, it would not be altogether happy. Concerning Mr. Wyatt's suggestion as to the use of an oily or bituminous substance for rendering the joints waterproof, that had been done in Italy. When in that country he (Mr. Aitchison) witnessed the spoliation of some beautiful and costly mosaic work, the white colour in which was obtained by the use of mother-o'-pearl, and he noticed that asphalte had been used. As to the excellence of mosaic as a groundwork for sculpture there could be no doubt, and it might be used for such purpose in this country almost generally, particularly as its cost would not preclude its use.

Professor T. HAYTER LEWIS said that for mosaic designs a very bright style of shade indeed was required. Instead of shadows lines were wanted.

Mr. J. P. SEDDON asked what, compared with the size of the tesseræ, should be the size of the joints, and also why, if a large surface of gold colour of one uniform tint was required, it should be broken up into small pieces if the same effect could be procured without?

Mr. LAYARD, in reply, said that in the Venetian work large surfaces of gold were not of one uniform tint, the skilful mosaicist avoiding a monotony of tint. Regarding the size of the tesseræ they varied considerably in St. Mark's, some being very small. Their size must depend on the taste of the designer. It was really a moot point whether cement should show between the tesseræ or not. In England the appearance of the cement was objected to as being coarse, but the English were too much afraid of coarseness in decoration. The tesseræ could be placed nearer to or farther from each other as thought desirable, but all these were secondary considerations, the great point being the adaptability of mosaic as a material for wall decoration in this country. Alluding, in conclusion, to the failure of fresco painting, Mr. Layard said that Dr. Percy had just declared against *all* painting in London, saying that coal-smoke would destroy every kind of painting on plaster.

Mr. FERGUSSON fully agreed with all that had fallen from Mr. Layard. As regarded the employment of red colours in mosaic, he said that at Constantinople there are some reds which are brilliant beyond brilliancy. These were found not in St. Sophia's, but in the other churches.

Mr. G. G. SCOTT, in putting the vote of thanks, said that there could be but one opinion as to the manner in which the subject had been treated by Mr. Layard. It was unfortunately the case that our modern decorators had not succeeded as they ought to have done in making their work durable. He (Mr. Scott) could not see why this should be so, except in London, where exceptional influences operated. Decorators always said that they must use oil or turpentine, or some vehicle of that kind, and that if they painted in distemper their work would perish at once, although when they painted in oil or turpentine their work was commonly found to fail from the most obvious of all causes—because the oil or turpentine in the paint prevented the damp in the walls from exuding through the surface, as it did in old times. As we did not succeed in fresco painting, then, nothing could be more important than to find another material. Mosaics, though not largely used in the ancient art of this country, was, nevertheless, not objected to by the mediæval artists, as is proved by several instances. In Westminster Abbey there are remains of mosaic which have stood to the present day unmolested except by the hands of pickers and stealers. That the work in the Abbey was done on the spot there were curious proofs. The marble is our own Purbeck, and in the concrete beneath the floor were found the chippings of the glass mosaics. The work was evidently done by Italians. In mosaic, strong lines, such as were seen in brasses, should be adhered to. The shades should be expressed by single lines, and not by hatching. Mr. Scott concluded by alluding to the mosaic work now being executed in Wolsey's Chapel, Windsor, by Messrs. Salviati and Co., and also to the mosaics for the Albert Memorial, Hyde Park. The cement used for the latter would be, he said, that usually used by Dr. Salviati, which had great toughness (although nothing like so hard as common cements) and promised durability. With regard to "stopping" the joints he (Mr. Scott) had almost made up his mind to use common boiled oil, taking great care that the plaster was well dried first.

Mr. LAYARD, in responding, said that the general appearance of the work at Windsor was satisfactory. In all such works, however, there was generally plenty to criticise and abundance of critics, but his general inclination was to take a work as a whole, and not in detached parts.

The meeting then adjourned.

ST. GEORGE'S CHURCH, CROYDON.

THIS church is being built for the English Presbyterian body from designs by Mr. John Thomas Barker, architect, Croydon. It consists of nave and transepts, and will have a tower and spire rising to a height of 120ft. A two-story building adjoins, which will be used for vestries, living and class rooms, and large school room. The whole is being carried out in red brick and Bath stone, with malm facings inside, and when completed will cost £4,000, exclusive of site. Mr. J. Pollard, of Croydon, is the builder.

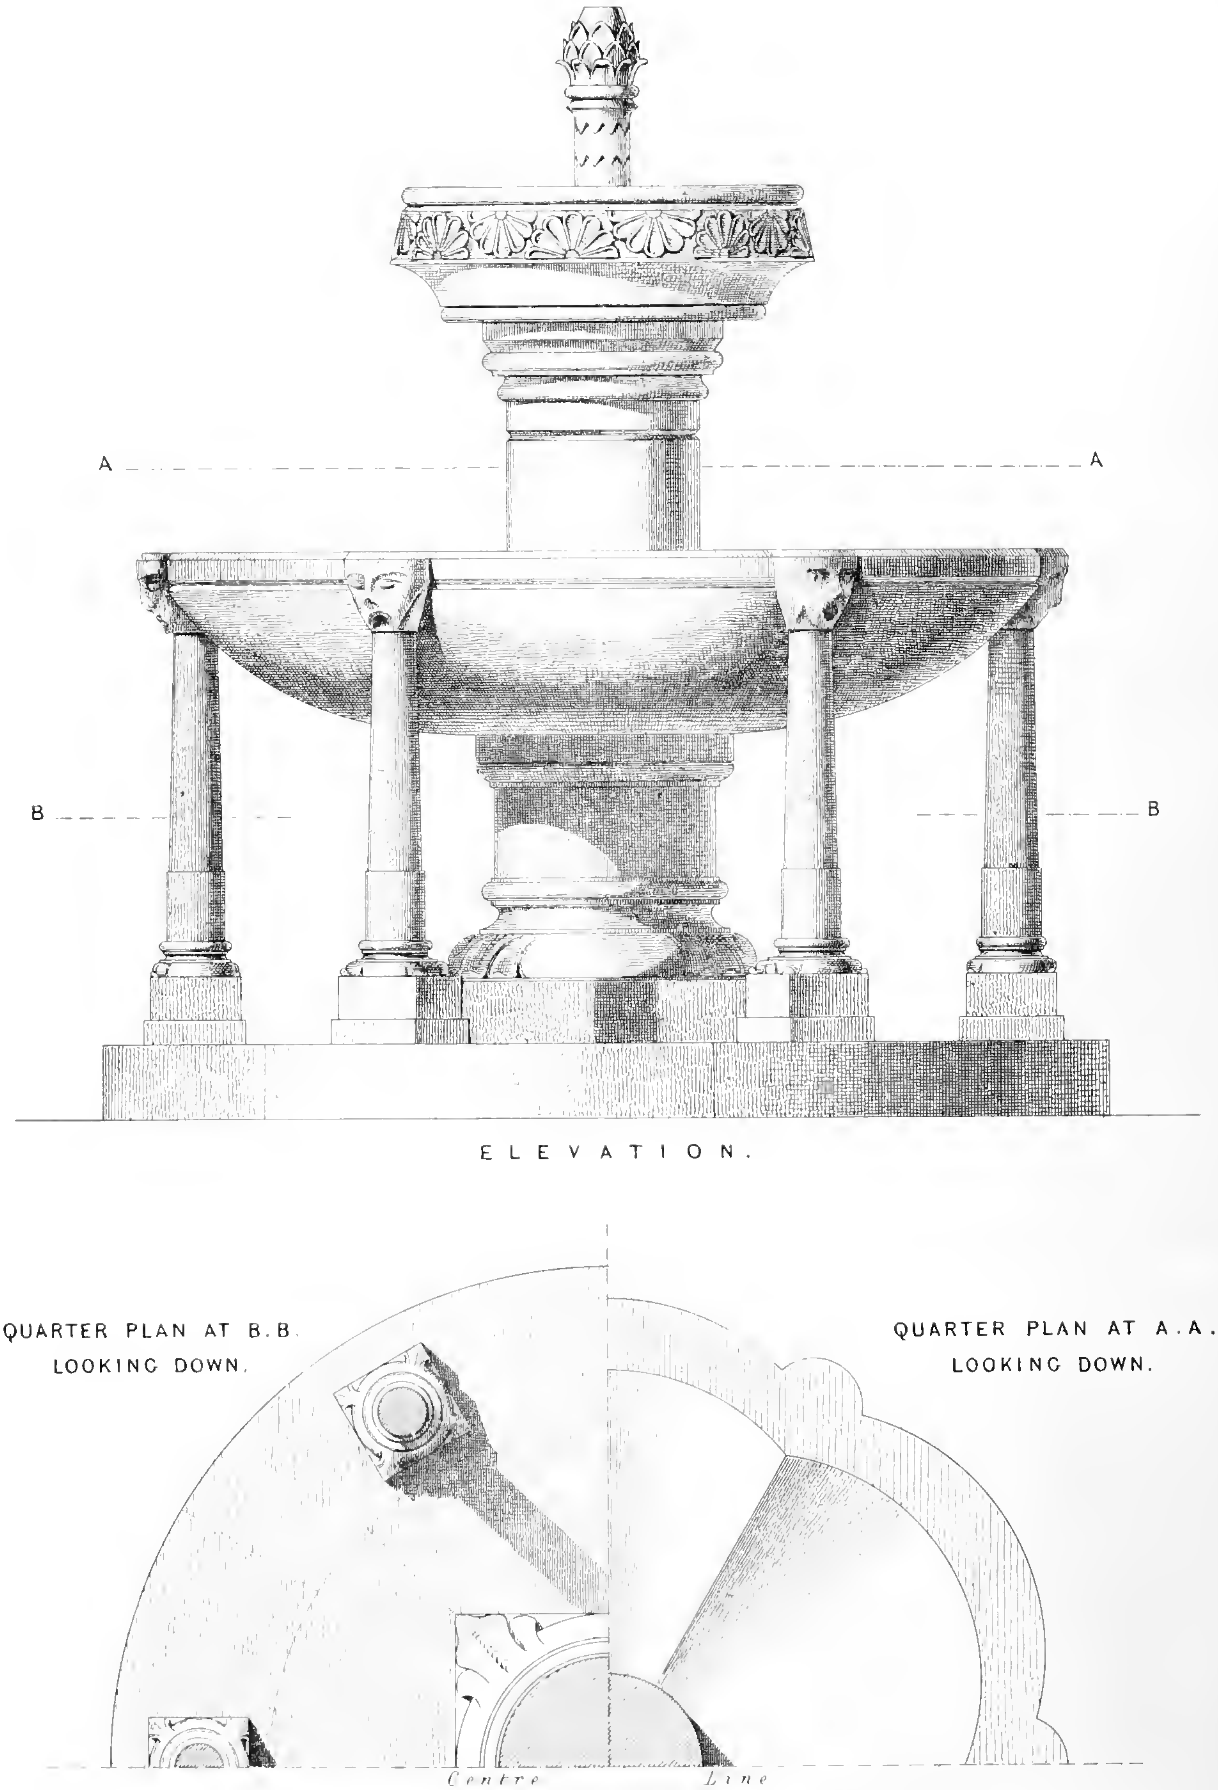
REFERENCE TO PLAN.

A. Porch.	F. Public Vestry.
B. Tower.	G. G. Class Rooms.
C. Lobby.	H. Verger's Living-room.
E. Vestry.	I. Verger's Sleeping-room.

NEW STREET SIGNAL.

AN experiment is being tried this week under the direction of Messrs. Saxby and Farmer, the railway signal engineers, by means of which semaphore signals and coloured lights will be made use of to regulate the street traffic. A pillar has been erected close to the entrance to Palace-yard. It is of an ornamental character, and it is about 22ft. high above the flagstone at its base. The centre of the semaphore arms, which are 4ft. long and 1ft. broad, is 18ft. above the flagstones, and the centre of the bull's eye a little over 20ft. high. The pillar will display three semaphore arms, two of which will face Bridge-street and Great George street, of course in the opposite direction, and will apply to the traffic in these directions. The third arm will face Parliament street on the left, and will extend in the direction of Bridge-street, and apply to the traffic between Parliament-street and Bridge-street. The arms will be moved simultaneously by one action on the part of the constable in charge. If he desires to stop the passage of vehicles or horsee he pulls out a horizontal bar conveniently adjusted near the base of the pillar, and this acting upon the mechanism within the pillar brings the arms to the horizontal position, and turns on the red light by the same pull. The bar has catches on its under edge for keeping the arms at the two positions. The only other position that the arms will take is the slope to the angle of 90 deg., which will be accompanied by a green light. The sloping position and green light prescribe caution, or relaxed pace in passing over the crossing. The lights will be gas jets, with burnished reflectors behind them, and in front a magnifying lens of 6in. diameter, with green and red glasses intervening according to the working of the apparatus. The change in colour is accomplished by the apparatus fitted in the interior of the lamp box, and not by the ordinary "spectacle" disc provision. The pillar is coloured bright green, relieved with gilding; and the semaphore arms, which are curved on the edges, and narrower at the inner than the outer ends, are coloured bright red with a gold border. If the experimental signal station prove successful, it is likely that the system may be applied extensively and advantageously.

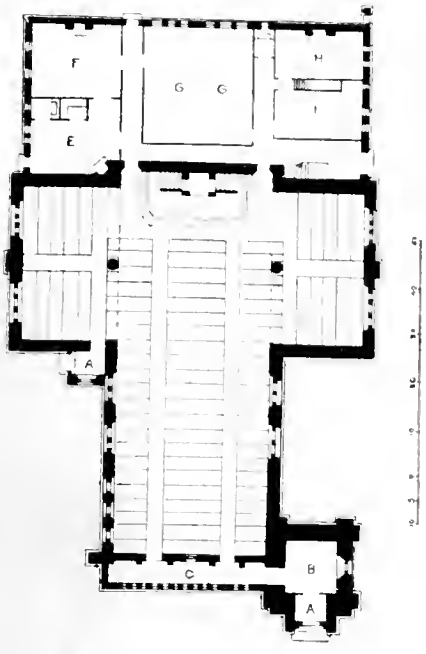
The lectures on sculpture will not be given at the Royal Academy this season.



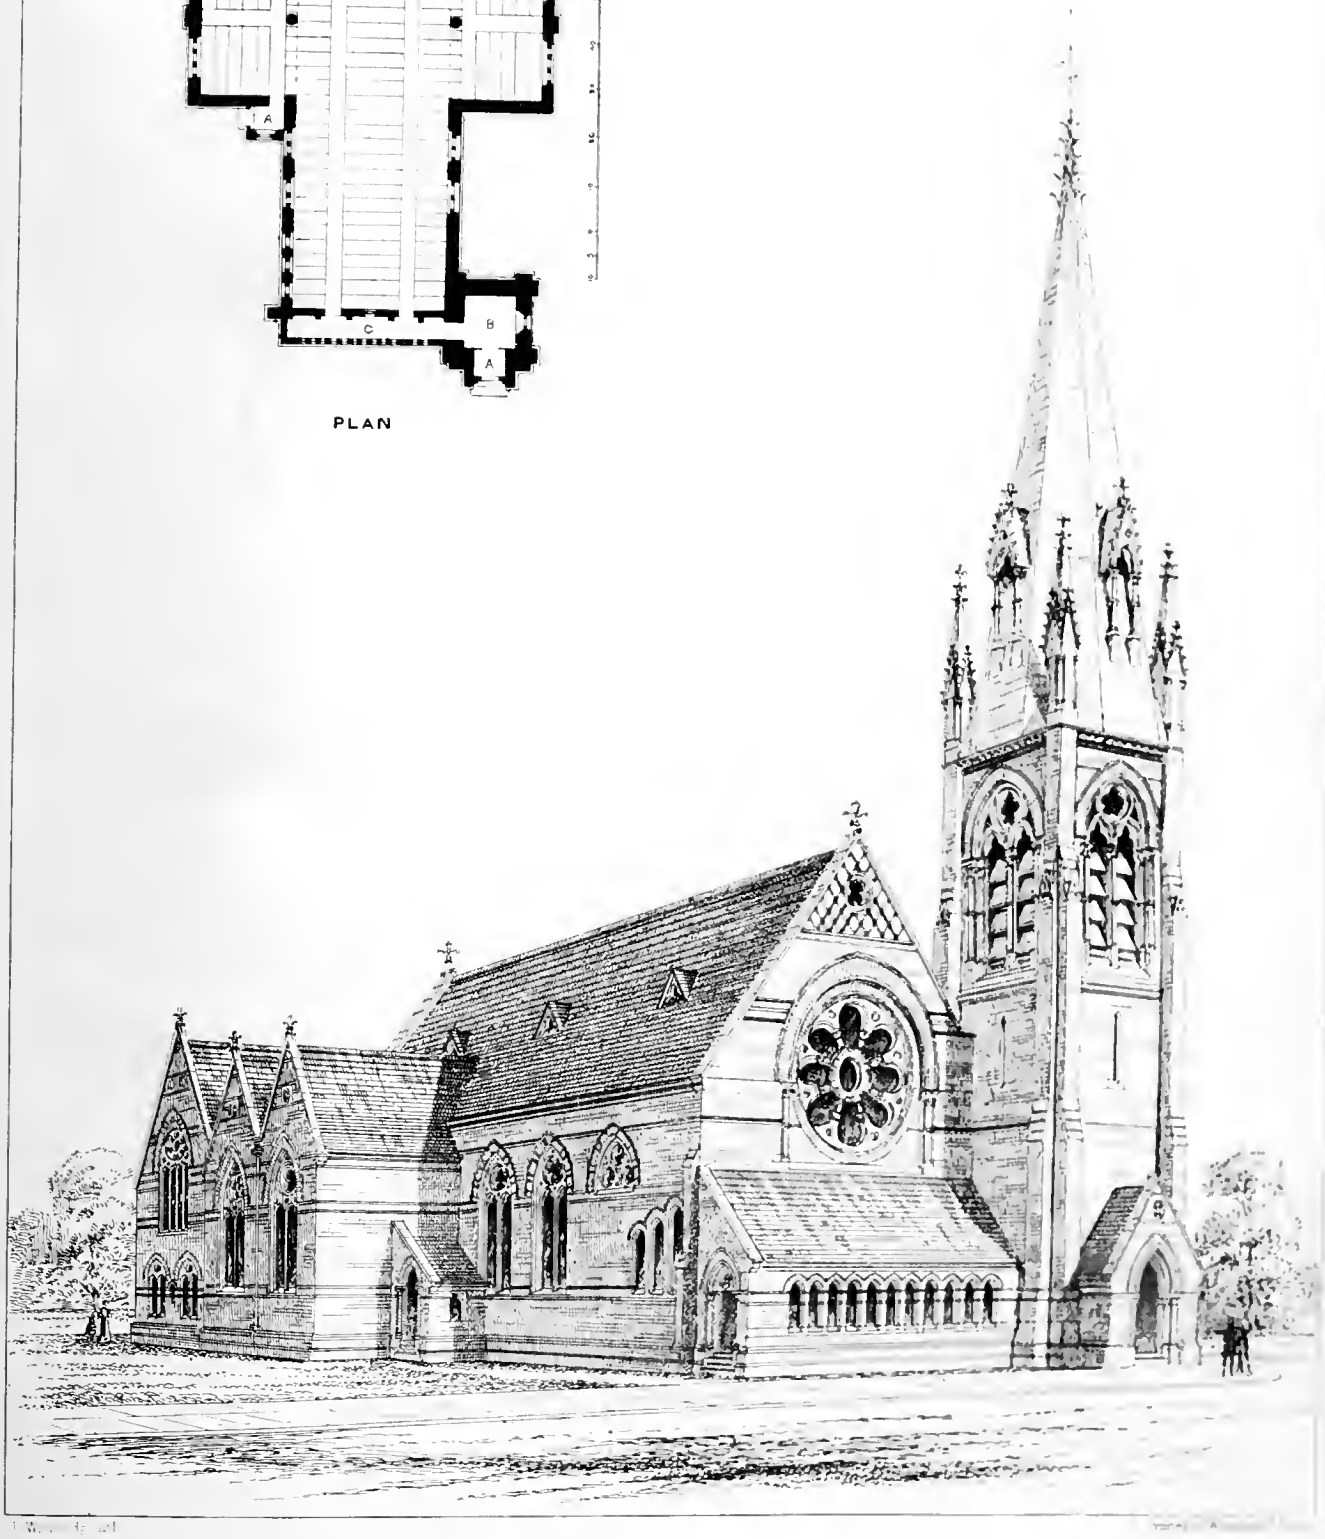
MEASURED AND DRAWN BY J. P. SEDDON.

H. A... Lith. Printed by Whiteman & Bass

Fountain at the Abbey of Sayn.



PLAN



St. George's Church, Croydon. — Mr J. THEO. BARKER, ARCHT

FOUNTAIN IN FRONT OF SAYN CHURCH.

FOUNTAIN IN FRONT OF SAYN CHURCH.

NEAR Bendorf, on the Rhine, in a ravine among the hills at some little distance from the river, is the old church of Sayn, once an abbey. Though not extensive it has many points of interest, and among them may be reckoned the pretty fountain which stands before the west front. We give a view of it from Mr. Seddon's work entitled "Rambles in the Rhine Provinces," together with a plan and elevation to scale from measurements taken by him. The material in which it is executed is dark limestone. It is evidently of the Transitional period, probably of the latter part of the twelfth century.

Building Intelligence.

CHURCHES AND CHAPELS.

The new church of St. Stephen, South Dulwich, was consecrated on Saturday week. Mr. Charles Barry is the architect, and the cost has been between £8,000 and £9,000.

A new Congregational Chapel was opened at Boston, Lincolnshire, on Tuesday week. It is built of red and white facing bricks, with Ancaster stone dressings, and seats 700 persons, at an inclusive cost of about £2,000. Messrs. Innocent and Brown, of Sheffield, were the architects, and Mr. S. Sherwin, of Widebargate, the contractor.

At the meeting of the Dean and Chapter of Gloucester Cathedral last week, Mr. G. Gilbert Scott, the architect to the cathedral, exhibited his designs for the restoration of the choir, which have been long under anxious consideration. The plans obtained the cordial and unanimous approval of the Dean and Chapter, and Mr. Scott received instructions to begin the work without delay. The nave will be immediately prepared for the celebration of Divine service during the time occupied by the performance of this work. The choir when thus restored will be one of the most beautiful specimens of architecture in the country. The estimate for the work now to be begun is about £15,000. The amount of the estimate for the whole contemplated restoration is about £40,000.

On Wednesday week a new Presbyterian Church was opened at Lewes. The style is Lombardic, and accommodation is provided for 400 persons. Attached to the church are vestries and commodious school rooms. The cost has been £2,500; Mr. W. F. Poulton, of Reading, being the architect, and Mr. Sawyer, of Dulwich, the contractor.

The first contract for the restoration of Stathern Church has been completed. The tower has been opened out to the church; a section of the old pewing has been removed from the nave and aisle and replaced with substantial oak benches. The interior of the chancel has been completely restored and fitted with ornamental oak benches. Mr. R. W. Johnson, of Melton and Leicester, was the architect engaged in the restoration, and the works have been erected by Mr. J. Fast, of Melton Mowbray.

The new church of St. Asaph, Birmingham, was consecrated on Tuesday by the Bishop of Worcester. The plan consists of nave, north and south aisles, chancel, and vestry underneath the chancel. The builder's estimate, exclusive of tower and spire, was £5,443, but the cost of land and other charges increased the amount to nearly £7,000. The warming arrangements are very good, and have been carried out by the London Warming and Ventilating Company. Mr. Y. Thomason, of Bennet's-hill, was the architect, and Messrs. Wilson and Son, of Handsworth, the builders.

The church of St. Mary the Virgin, East Barnet, Herts, was reopened on Saturday, November 28, after restoration and enlargement. The church is one of some interest, having been erected in the early part of the twelfth century by an Abbot of St. Alban's for the spiritual benefit of the poor inhabitants of that locality engaged in wood-cutting in the then surrounding forest, and a considerable portion of the ancient fabric still remains. The additions consist of a new south aisle built in the Early English style of architecture, with walls faced with Kentish rag stone, and windows and dressings of Bath stone. The roof, framed with open timbers, is covered with Staffordshire tiles. The arcade, opening from the ancient nave, is of two arches, supported by a polished marble shaft with richly carved capital. The whole of the works have been carried out under the superintendence of Mr. A. R. Barker, the contractors being Messrs. Bove, of Islington.

Shottisham Church, Suffolk, has just been reopened after restoration at a cost of £1,200. Mr. Edward Hakewell is the architect, and Mr. Henry Luff, of Ipswich, the builder. New school-rooms adjoining the church are now being built.

Kirtling Church, Cambridgeshire, was reopened on Thursday week, after undergoing considerable alterations and additions. The north wall has been rebuilt, and a new aisle and new roof to the entire fabric have been erected. Messrs. Clarke and Holland, of Newmarket, are the architects. The warming apparatus has been executed by Messrs. Weeks and Co., of Chelsea, and the carved pulpit, reading desk, and open benches are the work of Mr. Tooley, of Bury St. Edmunds.

The Duke of Norfolk, who comes of age on the 30th inst., has intimated, according to the *Weekly Register*, that one of his first acts on attaining his majority will be to lay the foundation stone of a large Catholic Church at Arundel, Sussex, to cost £50,000, the whole of the expense being borne by him.

The parish church of Hoxne, Suffolk, was reopened on Friday last, after having a new aisle added. The walls are of rubble, with quoins, stringcourses, and enrichments of Portland stone. The church, when originally built, had a nave and two aisles, but another north aisle was added outside the original one many years ago. The aisle just added is a corresponding one outside the south aisle. The church is consequently of great breadth. Mr. Francis, of London, is the architect, and the work was done by local contractors.

Beighton Church was reopened on the 3rd inst., after restoration under the direction of Mr. Rollinson, architect, of Chesterfield. The gallery at the western end has been removed, the western arch thrown open, and the high back pews replaced by benches of stained pitch-pine. The ancient entrance to the roodloft, and a Norman arch over the Pointed arch separating the nave from the chancel, which were both discovered during the progress of the works, have been entirely restored. The Tudor roof has been replaced by one raised to the original pitch. The builders were Messrs. Ash and Clayton, of Sheffield.

BUILDINGS.

The new parish school at Grimstone has been completed and opened by a successful bazaar. The building consists of a large schoolroom, anteroom, and out offices. Red brick and stone dressings are the materials used, and a bell gable in west side forms a feature in the building. The contract was taken by Messrs. Whait and Woolford, who have carried out the works under the superintendence of Mr. R. W. Johnson, architect, Melton and Leicester.

The foundation stone of the Bolney National Schools, Sussex, was laid on Saturday last, by Lady Victoria Wellesley. Accommodation is provided for 130 children. Messrs. Banks and Barry are the architects, and Mr. Skinner, of Storrington, is the builder. The estimated cost is £1,000.

New national schools were opened at Newhaven on Monday week. The style is Gothic, and accommodation is provided for 200 children. Messrs. Habershon, Brock, and Webb were the architects, and Mr. Morling, of Seaford, the builder. The cost was £600.

The Theatre Royal, Whitehaven, will reopen at Christmas, after having undergone a complete transformation internally, from designs by Mr. Jonathan Shepherd, architect.

We are glad to hear that the piece of land situated at the corner of Church and Paradise-streets, Liverpool, which has remained so long vacant, is about to be built upon. The lower portion of the building will be devoted to shops, the upper stories to offices, &c. The style adopted is Gothic, and the elevations will be executed in stone. The architects employed are Messrs. Haigh and Co., of Liverpool.

The mania for theatre building, so prevalent of late in London, has extended to Glasgow. Hitherto only one theatre has existed there, but there are now three. The most recently opened house is the Colosseum, which has been erected by Mr. J. S. Baylis, at a cost of £30,000. Especial care is taken for the comfort of the audience. A remarkable feature in the new building is the unusually large space underneath the stage, which is 30ft. deep, hewn out of the solid rock. This extensive space has been provided to facilitate the production of the numerous effects which the realistic drama demands.

The Woolwich Board of Guardians contemplate building a new workhouse on the highest part of Plumstead common (the most remote part of the whole district, and the farthest from the poor of the united parishes), enclosing for that purpose twelve acres of land, the only alleged advantage being that land is cheap. Apart from the sanitary question, and also that of convenience, a medical contemporary asks whether the board, charged with other responsibilities than the apparent saving of a few hundred pounds, has counted the cost of destroying one of the few open spaces still reserved near to our crowded cities.

On Saturday afternoon the foundation stone of a new Wesleyan School was laid at Farsley, near Bradford, Yorkshire. The style adopted is Italian. The building will be constructed of Horsforth stone, and will accommodate 500 scholars, at a cost of £2 000. Messrs. C. S. and A. J. Nelson, of Leeds, are the architects, their design having been selected in competition.

The Globe Theatre, in Newcastle-street, Strand, which has been erected on part of the site of the unfinished Strand Hotel, was opened on Saturday week. The lessee, Mr. Sefton Parry, has been his own architect in the matter, he feeling himself qualified so to act from his large experiences of theatre building, both in England and America. Construction may not suffer by such an arrangement, but æsthetics may. The theatre is a circular building, thus in a degree conforming to its name. The boxes are on a level with the street pavement, but the pit and stage are 12ft. below the surface of the ground The new house is about equal to the Olympic in size, but the accommodation is said to be far superior, and the ornamentation more attractive. Nearly 2,000 spectators can be accommodated, all of whom will have a clear view of the stage. The works were executed by Mr. S. Simpson, who also built the new Holborn theatre.

A new school has been erected at Gaddesby, at the sole cost of E. H. Cheney, Esq., of Gaddesby Hall. The part at present erected is one division of a block of buildings which, when complete, will consist of separate school-rooms for both sexes, and dwellings for master and mistress. The building is Gothic, of an ornamental character, and is of superior red pressed bricks with Bath stone dressings. The roof is open-timbered, supported on carved corbels, and the walls inside are of pressed brick, doing away with any need of plastering. Messrs. Herbert, of Leicester, were the contractors; and Mr. R. W. Johnson, architect, of Melton and Leicester, furnished the designs.

The new temperance hall and institute at Finedon was opened last week. The site is detached, having streets all round. The building, which is two stories high, comprises—on the ground floor—entrance and staircases, reading-room, spacious club room, kitchen, and dwelling-house for hallkeeper, and over the whole of these is the hall proper, which is a lofty, well-lighted room with handsome open-timbered roof. The building is of red Finedon stone, with Box stone dressings, and is Gothic in character. The works have been carried out by Mr. W. Henson, builder, of Finedon, from designs and under the superintendence of Mr. R. W. Johnson, architect, of Melton and Leicester.

TO CORRESPONDENTS.

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

RECEIVED.—H. H.—R. C.—W. H. C.—F. and Son.—E. R. P.—P. M. M.—C. P.—I. and W.—I. C. J.—S. W. and Co.—W. C.—C. T.—"Two little Goths"—"Vincent."—E. S.—H. H.—I. P. L.—T. R.—"Fairplay."—G. G. H.—B. L.—H. M.—E. W. G.—I. H.—G. H. G.—E. T.—G. M.—C. S. W.—J. M. S., "Her Majesty's Theatre" next week.—J. M. S., "The Art of European Decoration of Churches" next week.

A REGULAR SUBSCRIBER.—The contract price for the working men's institute illustrated in last week's BUILDING NEWS was £1,210, but the total cost, including the fittings and furnishing of lecture hall, reading-room, &c., together with architect's commission, was about £1,440.

Correspondence.

LOCAL BOARDS.

To the Editor of the BUILDING NEWS.

SIR,—I trust you will permit the correspondence which will doubtless ensue from the letter of "A Ratepayer," in your Intercommunication column last week but one, to appear in your general correspondence, as I am sure the hardships and difficulties caused by the various local boards to architects and their clients are such that most will have something to relate. With the intention in the first instance of improving the social and sanitary condition of dwellings, the Public Health Act has been so fettered by the bye-laws of the various districts that it becomes not only arbitrary but tyrannical. There would not be much to complain of if the Metropolis Building and Local Management Acts were applied to the suburbs; but when these are added to and each district has requirements peculiar to itself, the difficulty of carrying out works in three or four different places may be judged. I will not take up your space by enumerating what I consider the reasonable objections to the Act and bye-laws, but will only say that in a small town in the south of London a detailed copy of the plans and sections drawn to a certain scale and a specification of the materials used have to be submitted to the local surveyor a fortnight before the building is commenced, and no house is to be let without his certificate that the requirements of the board have been carried out. The question asked by "A Ratepayer" is an important one, and it appears that the local magistrates can only decide in accordance with the Act and the bye-laws sanctioned by the Home Secretary.—I am, &c.,

J. D. M.

GROTESQUES.

SIR,—Your correspondent, "A. R. T.," has blown Mr. Moyr Smith's trumpet, in your last impression, with an extravagance which may surely induce that gentleman, if he cares for the opinion of any but mediæval fanatics, to say, "Save me from my friends." I think that a great many of your readers will endorse the remarks of "G. S. A." in a previous number. I can certainly say, both for myself and for others who are known to me, that we have had quite enough of Mr. Smith's grotesques, and cannot tell why we are to be blessed with such a a number of them, unless as examples of a good free touch in lithographing, on which head I give Mr. Smith all credit, and only wish that his evident talents were made use of in producing less absurd and disagreeable forms. Nor can I deny that Mr. Smith's grotesques—*qua* grotesques—exhibit a good deal of ingenuity and invention; but, to my thinking, the revival of this *bizarre* method of decoration as a part of architectural design in the present day is simply a *gross and childish absurdity*, and is one of those things which tend to bring the profession of architecture into contempt among educated and philosophical persons among the outsiders. In what used to be termed the "Dark Ages," which are now dressed out as the "Mediæval Period," such a style of decoration was the expression of a genuine belief in the horrible and the monstrous—how genuine any one must be aware who has paid any attention to the legends of diablerie and witchcraft of those times. That it should be solemnly reproduced now, and that architects of reputation, who in other matters show evidence of refined and educated minds, should be content to disfigure their churches (and offices also, for the leprosy is spreading to "secular" buildings) with figures which seem only meant to frighten children, is only a proof of the extent to which people can become blinded to any absurdity when they once go in, through thick and thin, for any popular movement in art. None but those architects whose judgment and eye has become utterly diseased by their exclusive study and blind admiration of everything belonging to the middle ages, could seriously set themselves to work to perpetrate such things; and it would astonish some of these gentlemen, perhaps, if they could hear the tone in which such absurdities are commented upon by highly-educated and intellectual men *out* of the profession, who are sufficiently masters of their reason to be aware of the origin and real tendency of this current of barbarism. Even in an archæological point of view, the interest of these things has been much exaggerated. If the builders of Canterbury, for instance, had no better taste than to spend their time in carving the two heads delineated by Mr. Smith in your last number, were it not, perhaps, better to allow this melancholy fact to pass into oblivion? But, when a writer begins, like "A. R. T.," to talk about these grotesques "suggesting the embodiment in material of a real and soul felt religion which had almost died out, and is now being happily revived," it is impossible to read such stuff with patience. In the name of goodness, of what sort of a "religion" are these precious productions the embodiment, except of one of abject and ignorant terror and superstition, such as we know did exist in the middle ages, and any attempt at the reproduction of which would be met by the laughter of the common-sense public and the unmixed scorn of all minds of a higher class? I have not the slightest hostility to Mr. Moyr Smith, who appears at least to be a very clever and effective draughtsman; it is against the whole "grotesque" movement, the absurdity of wantonly disfiguring our buildings in this way, that I inveigh. To put such things gravely before us as "art," to decorate our churches with the most odious and uncouth forms that can be invented, is simply an insult to common sense and to artistic feeling.—I am, &c.,

H. H. STATHAM.

5, Batavia-buildings, Liverpool.

MODERN FURNITURE.

SIR,—A quotation from Mr. Eastlake's work, in your last number, contains the passage:—"Chairs are invariably curved in such a manner as to ensure the greatest amount of ugliness with the least possible comfort." Mr. Eastlake, I suppose, was here speaking of the upright curve or ornamental turn usually given to the chair-back. Although this *is* often ugly I think that, for lightness, convenience of grasping, and the prevention of bruises, the chair-back *should* generally be a curved rail; but it seems to me that the curve of chair-backs as usually made is wrong on *plan*. Instead of being concave to the body it should be slightly *convex*, and in the middle, from the top to the seat, should run a pad which would fill the hollow of the spine and really support the body. On leaning back in an ordinary chair the shoulder blades touch first, and in order to rest the spine the body is curled up slightly (contracting the chest)—a position by no means healthy, and often causing (to me, at all events) a feeling of oppression; but introduce a thin bolster so that the shoulder blades may be thrown slightly back and the spine rested, and immediately relief is felt and the breathing becomes freer. Of course, to be comfortable the back legs of a chair should be shorter than the front.

I suppose this idea is not new, but I shall be glad to hear if chairs on this principle are made by any London firm.—I am, &c., A. C. G.

10, Brecknock crescent, December 2.

THE MEASUREMENT OF IRREGULAR PLANE FIGURES.

SIR,—It may not be unacceptable to the readers of your valuable columns if I advance a little on the measurement of irregular plane figures. It is generally the custom of surveyors to employ some mode of straightening the crooked bounds in order to condense the calculation and render the operation simple; exactness seems to have first called for the use of the parallel rule, to continually reduce the sides of the polygon to a figure having one side less, but which will contain the same area. It is grounded on Euclid's proposition of reducing a trapezium to a triangle, but the method is too tedious for general practice, and the one mostly adopted seems a horn ruler or strip of glass, and the parts of the figure are equalised by inspection. It has been thought advisable, from the numeral figures required to work out a large plan, to abandon calculation altogether, and reduce the process to a mechanical operation, to do which several ingenious means have been resorted to, the most novel of which that occurs to my remembrance is to cut to pieces the original mass and weigh the parts in a delicate balance, the area being deducible from tabulated results, but from many inaccurate results I have not seen the system practised a long time. The most modern practitioners make use of an instrument for this purpose, which, exclusive of damaging the plan, registers the contents complete and safe without any calculation, and thereby does away with the liability to error which will be sure to creep in in vast numbers of figures. Tracing paper is procured of good quality and lines ruled thereon one chain apart; it is then placed over the figure whose area is required; the instrument, which consists of a thin strip of wood and a brass slider, is placed over the tracing paper, and by means of a hair in the slider, the irregular parts at either end of each strip are equalised by the eye; from the first strip the instrument is taken to the next strip, and so on to the whole figure; the contents are then read off at once in acres, roods, and poles. Another most simple and reliable practice which I have frequently adopted is to rule tracing paper all over in squares of one chain each, laying the same over the irregular figure and then, counting the squares for the contents, the broken squares at the extremes of the figures are judged of in content by inspection. If some of your readers will look to these things, much valuable time may be saved and

many errors prevented, and if I have not explained these things so clearly as I ought, I shall be happy to furnish practical information thereon.—I am, &c.,

ROBEY CARPENTER, Land Surveyor.

Builder's and Contractor's Offices, High-street, Great Marlow, December 7.

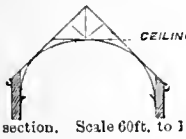
GRAY'S INN SQUARE.

SIR,—Going into this square (north) the other day I was struck with its extremely dismal character; and at the same time the ease and cheapness with which it could be greatly improved. It will be remembered that it is a large quadrangle enclosed by very old houses of uninviting appearance, mostly in want of a thorough renovation, and the general area is a dull monotonous extent of bare gravel without any relief How very simple it would be, and how moderate the cost to a wealthy society like that of Gray's Inn, if a small pleasure ground were laid out in the centre of this quadrangle, the same as in any other London "square." To have grass, trees, and evergreen shrubs in this bald and desolate place would be a vast improvement. Those will form the best idea of the change who remember the alterations made to Kennington-common (now Kennington-park), Bartholomew Hospital grounds, and Paddington-green, from a similar state of neglect and ugliness to improvement and beauty. If it were thought any object to have exceedingly direct access from side to side of the square, a path might be made across the enclosure, or the garden could be laid out in a circular form, so that only a small detour would be necessary. I am sure there is wealth enough, I am sure there is intelligence enough, and I hope and trust there is activity and energy enough in the honourable society to effect this salutary adornment to its property forthwith.—I am, &c., H. R. P.

Intercommunication.

QUESTIONS.

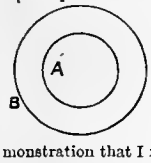
[1162.]—ROOFS.—Will some able correspondent show me geometrically how to determine the proper strength for the principals to a roof of 45ft. span—the principals to be



Cross section. Scale 60ft. to 1in.

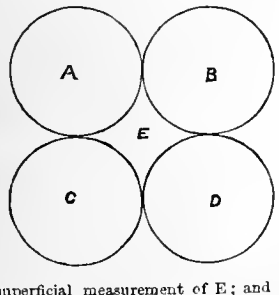
either of iron or wood, to be 12ft. apart, and of the outline shown in the diagram?—A. B.

[1163.]—AREAS OF CIRCLES.—Can anybody give me or tell me where I can get the demonstration of the following problem?—To describe a small circle (A) within a larger one (B) in such a manner that the circle A shall occupy exactly half the area of the circle B; that is to say, if the circle A were taken away it would leave a ring of exactly its own area It is the geometrical demonstration that I require.—C. E. O.



[1164.]—THE CHEAPEST ROOF FOR BUILDING.—Can any of your correspondents give me the necessary information upon the following questions by your next issue? What would make the cheapest and strongest constructed roof for a building being 45ft. between the walls? If an iron roof, what should be the proper size of the tie rods, struts, and principal rafters? also the proper distance between each pair of principals? Supposing the building should have an iron roof, I should then cover it with 1¼in. boards, and the boards covered with Duchess's slates.—WILLIAM SANDS.

[1165.]—SUPERFICIAL MEASUREMENT.—The diameters of circles A, B, C, and D are 6ft. I shall feel obliged if some kind friend would inform me how to ascer-



tain the superficial measurement of E; and again, supposing the said circles were 3½in. diameter, how should I proceed?—GRATITUDE.

[1166.]—TEST FOR PORTLAND CEMENT.—Can you, or any of my brother readers, inform me of a simple and ready test for Portland cement?—CEMENT ADVOCATE.

[1167.]—PAINTING ZINC.—Can any subscriber recommend a composition of oil colours that will adhere to zinc and resist the changes of the atmosphere? I find great difficulty in getting oil paint to stick on at all, and even then it is by no means durable.—VILLAGE BUILDER.

[1168.]—CRUSHING WEIGHT OF DRAIN PIPES.—What is the crushing weight, or fair load for a 9in. and 12in. stoneware vitrified drain pipe when set on end able to bear, supposing their average length to be 2ft. long? and at what depth should they be laid horizontally under a cart road to be out of danger of breaking?—JONATHAN JOINER.

[1169.]—CHIMNEY POTS.—A few days since the sweep swept my chimney flues, and a day or so after down came part of a chimney pot on my roof, all caused by the top of the sweep's broom. I shall be glad to learn if the abominable and everlasting disgraceful pots will ever be done away with, and if we are to retain such unsightly ornaments; and if there are any that are durable and that can be recommended to bear the scraping and brooming of the sweep? SOOT O!

[1170.]—WEIGHT OF ICE.—What is the weight of one cubic foot of ice?—JACK FROST.

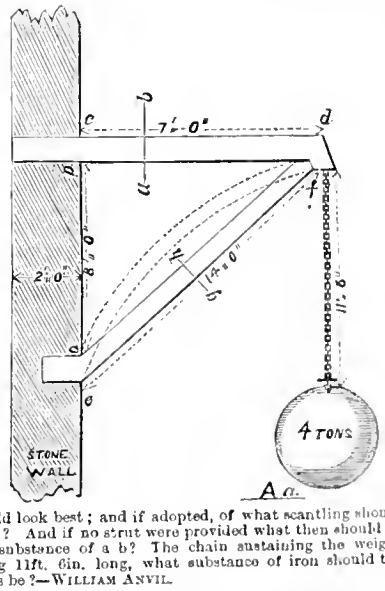
[1171.]—SYLVESTER STOVES.—Can any of your numerous readers inform me where Sylvester's stoves, formerly made by Allen and Son, Glasgow, are now to be obtained, or who has the patent?—JAMES W. JAMES.

[1172.]—INDIAN INK.—How can Indian ink and colour be made to lay well on tracing cloth?—B.

[1173.]—MAY'S SYSTEM OF CONCRETE BLOCKS.—Will some one please inform me if the manufacture of cement concrete blocks (Mr. May's system) is the subject of a patent? and if so, in what respect is it claimed to be a novelty?—CONCRETE BUILDER.

[1174.]—HOUSE CISTERNS.—Would you or some of your readers kindly inform me how the contents of cisterns for house supply may be properly calculated? Eight adults and 12 children under 7 years of age occupy a house, and the washing is done on the premises. It is proposed to fit up two cisterns; one to be supplied from the public service, and sufficient for all requirements, the second to receive and store rain water from the roofs only. I shall be much obliged by having the process of calculating the necessary contents of each cistern pointed out. HENRY CARTER.

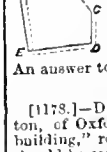
[1175.]—STRENGTH OF BEAM AND CHAIN.—I shall feel grateful if some kind friend will inform me what the thickness and depth of a cast-iron beam should be at a b, and the weight that should be built on its end to sustain a constant weight (A a) of 4 tons. Also the thickness of under strut, and depth of g h. The curved dotted strut



would look best; and if adopted, of what scantling should it be? And if no strut were provided what then should be the substance of a b? The chain sustaining the weight being 11ft. 6in. long, what substance of iron should the links be?—WILLIAM ANVIL.

[1176.]—WEIGHT OF CEMENT CONCRETE.—What is the weight of a cubic yard of cement concrete?—T. T. W.

[1177.]—HEDGES AND DITCHES.—If in the annexed diagram, A B C D E, the dotted line represents a hedge, and the clear line a ditch by the side of the hedge, which enclose a piece of land, In measuring this field what portion of the hedge and ditch is considered as belonging to the field, and what distance from the centre of the hedge is allowed for the ditch? An answer to this will oblige.—NIX.

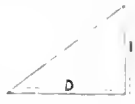


[1178.]—DAMP-PROOF FLOORING.—Professor Rolleston, of Oxford, in some remarks on "Scientific House-building," recommends that the floors of outhouses, &c., should be covered with a layer of gravel mixed with gas tar. Can any reader of "Intercommunication" give the proportion one ingredient should bear to the other?—ANTI-RHEUMATISM.

REPLIES.

[1112.]—STRENGTH OF WALLS.—If "J. L." would give a little more attention to what I stated respecting this question, he would see that I have not made a "muddle," as he terms it, of the equation. I suppose he would be good enough to point out in your next what is the difference between my equation and his, which he imagines to be the only "correct card." His values for the symbols I and H are the same as mine And perhaps he would inform me if it were possible for anyone with an eye in his head not to perceive by the dotted lines which way the wall would turn, and to see that A has been put, by an error in the cut, on the wrong side of the wall His remarks are merely quibbles. A G will consequently be the same as a b in his cut; that is, the horizontal distance from the joint A to the centre of gravity. His assumption of W = the weight of the wall is an absurdity, for the weight of the whole wall has nothing to do with the question of the strength and stability, which are always calculated for a cross section, considered to have a length of one lineal foot People are very apt to consider a thing a "muddle" when they do not comprehend it The centre of gravity of the wall, supposing it were rectangular in shape and homogeneous in consistency, will, of course, be in the middle as every schoolboy knows. I would advise your correspondent not to jump so quickly at wrong conclusions. HUTTON.

[1114.]—I am much obliged to "J. L." for his explanation why the moment of the earth should be doubled for stability. For a rectangular wall, this gives a thickness for stability twice that required for equilibrium, but for a wall of any other form, as in the sketch, it does not do so. Therefore, is it to be taken as a general rule, applicable in all cases, to double the overturning force to find the thickness required for stability, and not to double the thickness found for equilibrium? In a wall of this form, for instance, the weight is $\frac{W H D}{2}$, W being the weight of a cubic foot, and its moment is $\frac{W H D}{2} \times \frac{2 D}{3} = \frac{W H D^2}{3}$, the earth or water pressing against the vertical side. Then if O = moment of earth or water, for equilibrium $O = \frac{W H D^2}{3}$, and $D = \sqrt{\frac{3 O}{W H}}$; and if thickness thus found is to be doubled for stability, it will be $D = 2 \sqrt{\frac{3 O}{W H}}$. If, however, the moment of the overturning forces is to be doubled, it will be for equilibrium $O = \frac{W H D^2}{3}$, and for stability $2 O = \frac{W H D^2}{3}$, and $D = \sqrt{\frac{6 O}{W H}} = \sqrt{2} \sqrt{\frac{3 O}{W H}}$. The base D found by this method being to that found by the former as $\sqrt{2} : 2$.—X + Y.



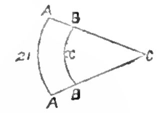
[1128.]—CALCULATION OF PRIME COST.—Recurring to the question of prime cost I think most men will agree with "Builder's Clerk" that it is not solvable with mathematical accuracy, nor with so close approximation as Mr. Duffield professes to have attained, whenever more than one job is being carried on from a central establishment. How, in such cases, can the values of items 4, 8, 10, and 12, in my calculation given in your last number, be other than approximate? In very exceptional cases, item 4 may not exist; the entire of the plant and materials may be purchased specially for a contract, and the former and surplus of the latter sold when the works are completed, then items 8 and 12 can be had exactly Item 10 will remains to be disposed of. Fancy a job so small that the foreman on the ground keeps all the accounts connected with it, or so large that a special office staff is set up for its working. Fancy all those conditions fulfilled, then in the absence of clerical errors you have your prime cost to a shilling, and some extremely fanciful notions also.—HENRY CARTER.

[1128.]—In further comment on this subject I beg to say I like the reply given by "A Builder's Clerk," in yours of the 4th, to Mr. Duffield, and further I should like to be informed by the same professional gentleman if there is a better way of preserving the prime cost of a contract than the one employed by myself In my waste book among other matter is entered the material used in the contract at as near per cent. as I can conveniently get, and also exactly my labour charged and sundry incidentals From this book, as per double entry, it is all journalised and twice posted contrawise in the ledger, accounts being opened for things as well as persons or contracts. When a contract is closed my prime cost is roughly summarised, and if less than the estimate I make the difference dr. to profit and loss, but if the percentage is greater, then of course the profit and loss is debited and the contract credited I conclude that approximation to the prime cost is only possible, yet my accounts will show the same nett profit in total at the ledger's close as though the cost price was set down ever so truly, for in the goods accounts on the dr. side stands all my prime cost or things that I buy, and on the other side all that I sell or charge for, including not the supposed percentage of contracts, but the amount of estimate, as although in this account the actual percentage is originally credited, yet the difference, of a gain is credited also for this goods account and the profit and loss account, *mes synonymous*. Mr. Duffield is too hasty and too conclusive in his reply to Mr. Badger, for I fear from the tone of his communication he does not keep his accounts even so clearly and as completely as the last named gentleman, whose books by the Italian method are quite a model.—ROBEY CARPENTER, land surveyor, Great Marlow.

[1138.]—THIEVES' VINEGAR. Thieves' vinegar contains the volatile oils of wormwood, rosemary, sage, spearmint, rue, lavender, calamus aromaticus, cinnamon, cloves, nutmegs, and garlic, extracted by maceration in strong vinegar. After the fluid is filtered The repute of this vinegar as a disinfectant is founded upon a story, that four thieves, who plundered the dead bodies during the plague at Marseilles with perfect security, on being questioned respecting the cause of this impunity, confessed, on the condition of their lives being spared, that they attributed it solely to the use of the above aromatic vinegar.—K. G

[1143.]—LAYING RAILS.—I think that "Contractor" may ascertain near enough for practical purposes the length of the iron rail by stating the case, that as the radius of the curve described by the outer rail is to the radius of the curve of the inner rail, so is the length of the arc, 21ft., to the length of the arc required—in this case 20.18ft., supposing the outer radius to be 202ft. 6in., and the inner 197ft 6in.—Z.

[1143.]—"Contractor" can compute the length of the inner rail thus:—



A B being the gauge.

A A : B B : : A C : B C

21 . x : : 200 : 200 — 4' 8½'

$\therefore x = \frac{2 \times 195.2916}{200} = 20.505' = 20' 6'$, the required length of inner rail —C. D.

[1143.]—I see your correspondent "Contractor" is in want of a solution to his very practical query. If I were laying anything out of a similar kind I should chalk it out one-tenth the size on the floor of a large room, and for all practical purposes that would be near enough. But to demonstrate it by figures is the easiest way I know. The radius is 200ft., therefore 200 × 2 = 400ft. = diameter; then 400 × 3 1416 = 1256 64, circumference of the outer rail. But there is a distance of 4ft. 8½in. gauge between the rails; therefore 4ft 8½in. × 2 = 9ft. 5in.; then 400 — 9ft 5in. = 390ft 7in., diameter of inner line of rails; 390ft. 7in. × 3 1416 = 1227.0566, circumference of inner rail. And both the circumferences being got, any parts of them included between two radii will bear the same proportion to one another as the two circumferences do to each other. Therefore, as

1256.64 : 1227.0566 : : 21 to 20.50 or 20ft. 6in. length of inner rail.

```

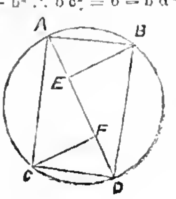
Hoping this will satisfy "Contractor."—GRAY.

[1144.]—THE STRONGEST BEAM THAT CAN BE CUT OUT OF A LOG.—On the assumption that "One who Takes Nothing for Granted" is familiar with the formula for the breaking weight of timber, this construction is readily explained thus:—Let a B = b; B D = C; and A D = d. Now the breaking weight varies as $C \times \frac{b c^2}{l}$.

Breaking weight varies as $b c^2$. In order for $b c^2$ to be a maximum, you must equate = o and differentiate $c^2 = d^2 - b^2 \therefore b c^2 = o = b d^2 - b^3 = o$ differentiating—



$\therefore d^2 \, d b - 3 b^2 \, d b = o$

$d^2 \, d b = 3 b^2 \, d b$

$d^2 = 3 b$

$b^2 = \frac{d^2}{3}$

It is evident that by this construction the beam fulfils the condition necessary for it to be a maximum, for

A D, A E = A B²

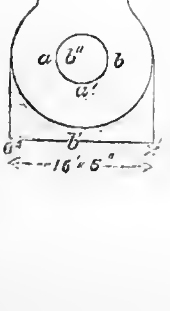
$d \times \frac{d}{3} = b^2$

$\frac{d^2}{3} = b^2$ A E D. C. D.

[1144.]—The way I would prove Molesworth's formula for cutting the strongest beam out of a log is by comparison of two beams cut out of a fir log, say 12in. diameter and 12ft. long. The scantling of a beam cut out of this log, according to the formula, would be 9 8in. by 6 93in; let the other be 6in. wide; its depth will then be 10.4in. Now applying the formula $W = c \frac{b d^2}{L}$ to these two beams we obtain—

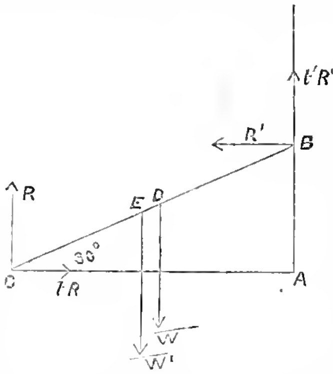
In the first—$W = 4 \times \frac{6.93 \times (9\ 8)^2}{12} = \frac{4}{1} \times \frac{6\ 93 \times 96}{12} = \frac{2661\ 12}{12} = 221.76$ cwt.; and in the second—$W = 4 \times \frac{6 \times (10\ 4)^2}{12} = \frac{4}{1} \times \frac{6 \times 108}{12} = \frac{\ }{12} = 216$ cwt. The former is, therefore, the stronger beam. In the same way it may be shown that the former is stronger than a beam of any other scantling cut out of this log. ∴ a beam cut according to the formula is the strongest beam that can be cut out of the log.—W. E. S.

[1145.]—STRENGTH OF JOINTS.—The relative proportions of the pin and head of the links composing the chain of a suspension bridge have been arrived at experimentally by Sir C. Fox, after the construction of the Kieff Bridge, in Southern Russia. He conducted three experiments. 1st, With a link similar to that used in Kieff Bridge, viz., O X = 10¾in. × 1in., a b = 4 5in., O¹ X¹ = 15.5in; this should have stood at least 210 tons, but it failed with 180 tons, by going at a and b, and a' and b'. 2nd. O X = 10¾in. × 1in., a b = 4.5in., O¹ X¹ = 18 5in. This one gave way with the same weight, and at the same places. This naturally led him to suppose that the bearing surface at a b was not sufficient. 3rd. O X = 10¾in. × 1in., a b = 6in., O¹ X¹ 16 5in, as shown in sketch. This was torn with 240 tons. He recommends a b = 6.5in.

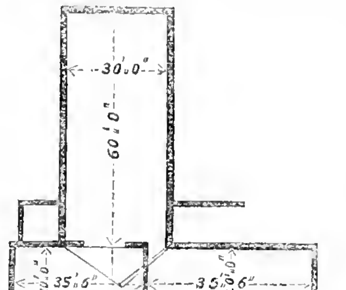


From this the rules are deduced:—1st, Two thirds diameter at O X = diameter of pin; 2nd, O X + a b = O¹ X¹.—C. D.

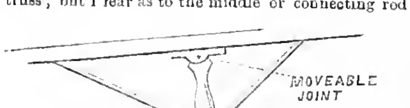
[1149.]—FRICTION.—The annexed diagram represents all the forces acting. R = reaction of the ground; R¹ of wall; D is the centre of gravity of the ladder, which is at its middle point; and E is the assumed point that the man has reached on the ladder just as it is on the point of sliding; therefore the frictions will act in the opposite directions to which the motion takes place, and are represented by t R and t¹ R¹; t and t¹ being the coefficients equating the several forces, and taking moments round C. R + t¹ R¹ = W + W¹ (1); R¹ = t R (2). W × C D × cos. B C A + W¹ × D E cos. B C A = t¹ R¹ × C B cos. B C A + R¹ × C B, sin. B C A from (1), and (2) $R = \frac{W + W^1}{1 + t\,t^1} = \frac{238}{1.3} = 183$ q. p. R¹ = t R = 183 × .6 = 109.8; substituting these values in (3) we have 84 × 15 cos. 30° + 154 C E cos. 30° = 54 9 × 30 cos 30° + 109.8 × 30 × sin. 30°; taking cos. 30° = .866 and sin. 30° = .5, and solving for C E, $C E = \frac{1982\ 1}{133\ 364} =$ 14.86ft. This the length up the ladder the man can go. If the vertical height be required, it = C E × sin. 30° = 14.86 × .5 = 7.43ft.—C. D.



[1151.]—ROOF CONSTRUCTION.—I feel somewhat interested in the inquiry made by "R School," having put on a roof precisely the same in construction to schools called Rector's Park Schools, Sunderland. The scantlings are very much the same, and plastered to the span; and, in addition to its own weight, each portion of the roof has on it an immense ventilator, as large almost as a small entrance lodge. When it was sparred ready for slating it was tested by a hurricane of wind, which, acting on the ventilators, brought the entire roof away from the gable wall, shaking and straining it tremendously. I got it forced back to its position, and, so far as I know, it stands all right and safe. I give a rough sketch of the plan of the building. The pitch of my roof appears to be much higher



than my friend's, for I find on referring to certain data the legs for the 30ft. span are 22ft., the rods 11ft. 6in. each, strut 3ft. Thus, so far as each leg is concerned, it is a complete truss; but I fear as to the middle or connecting rod



being right as a tie for a roof of a flat pitch. My own conviction is, that no principle which excludes the old-fashioned tie beam or tie rod from foot to foot is right or safe. I have put on a spandrel roof, which would certainly have come to grief; in fact, three of the legs did give way, and three of the spandrels broke, and tie rods had to be resorted to to prevent the entire roof falling in. I am thoroughly convinced that for a roof of the ordinary flat pitch it is neither wise nor safe to have anything but a good king or queen post, coupled with foot beam or rod. I cannot tell my friend the weight.—PRACTICAL BUILDER.

WATER SUPPLY AND SANITARY MATTERS.

A LOCAL paper says that the corporation of Sudbury has received a peremptory order from the Secretary of State, directing that body to proceed within fourteen days to take steps for the construction of waterworks for the town. The corporation has directed Mr. Hennell, engineer, of the Adelphi, to make a survey of the town.

Professor Frankland reports that the water supplied by the Southwark and Vauxhall Company which was "exceptionally contaminated" during August, September, and October, has now returned to its normal condition.

A new catchpit and interceptor has been invented by Mr Chesshire, of Newhall street, Birmingham. It consists of an iron box or tank, one corner of which is screened off by a coarse perforated iron sieve, which permits the aqueous fluid to pass directly into the drain, and retains its more solid matters. The bottom of the tank is covered with coarse cinders, with a layer of ashes above them, and it is then placed beneath a watercloset or dry seat, as the case may be. It is stated that only one seventeenth, or 6 per cent. of the solid matter passes through the interceptor, and that the contents retained contain 40 times more nitrogen and 300 times more phosphoric acid than the outflow fluid. The tank requires removal from time to time for the purpose of cleansing, the period varying according to the use made of it. The mode of fixing is simple, and the contents, when mixed with a sufficient quantity of earth, form a valuable manure. Mr. Chesshire states that it is the united presence of fœcal matter and water which alone gives rise to smell; and that the immediate separation in the interceptor purifies the drains and preserves the solid matters from unwholesome decomposition. The interceptor is to be tried at the Military Hospital at Netley. It is an apparatus well suited for particular places.

BUILDING AND LAND SOCIETIES.

THE members of the National Freehold Land Society held their quarterly meeting at the Guildhall Tavern, on Friday evening, 27th ult., Mr. Monro, one of the directors, in the chair. Mr. W. E. Whittingham, the secretary, read the account for the quarter ending October 30, as follows:—Receipts—Cash, July 31, 1868, £21,484 1s. 3d.; deposits from members, £132,709 4s. 1d.; advances to members repaid, £24,284 10s. 2d.; British Land Company, £49,417 6s. 7d.; other advances repaid, £29,032 19s. 6d.; entrance and transfer fees, £118 9s.; fees for surveying property, £119 15s. 6d.; total, £257,171 6s. 1d. Payments—Deposits withdrawn, £112,891 12s. 5d; advances to members, £29,398 11s. 1d.; British Land Company, £61,965 0s 10d.; other advances, £39,000; dividends and commission, £296 9s. 4d.; sundry expenses, £1,781 5s. 8d.; cash, October 31, 1868, £11,838 6s. 9d; total, £257,171 6s. 1d. The Chairman briefly moved the adoption of the report. The motion was seconded by Mr. Crellin. The report was adopted, and on the motion of Mr. Clarke, seconded by Mr. Smith, a vote of thanks was given to the chairman, and the proceedings terminated.

WAGES MOVEMENT.

THE master builders of Halifax have addressed a circular to the operative masons, requiring certain alterations in the trade rules now in force. From these it appears that the rules relating to the reckoning of time and quarter time and payment of wages are to be rescinded, and in future 7d per hour shall be the rate of wages for skilled workmen throughout the year; that all rules forbidding or interfering with the employment of machinery or machine-worked materials, or forbidding the use of stone worked at a quarry, or elsewhere than the place where it is to be used, are to be abolished. All trade rules, disputes, demands, and differences shall be settled for the future by courts of conciliation and arbitration. The masters also declare that at any time, upon six days' notice, they will be prepared to meet the men publicly to appoint arbitrators and mutually select an umpire. The alterations are to come into force on June 1, 1869. A circular has also been issued to the operative stone masons and bricklayers' labourers in the town, by which the ordinary rate of wages to be given throughout the year is fixed at 4½d. per hour. All disputes in this branch are also to be settled by courts of arbitration.

The board of arbitration lately established in the Potteries district, and which is composed equally of representatives of masters and men, have held their first sitting this week, the dispute submitted resulting in favour of the men. The subject was the preparation of clay for the use of potters. By a new process the labour of the men has been reduced, and at some works it has been sought to make a reduction of wages in consequence. This was resisted by the men, and the arbitration board was appealed to. The board decided that the deduction ought not to be made. Thus the board adopt the view of the men that, if they are saved some trouble, the masters are benefited by the improvement of their ware under the new process.

A partial strike has taken place among the masons of Blackburn, but is at present confined to a single establishment. The men have struck for the express reason that there are some other men (non-society men) working stone at the quarry. The masons refuse to allow the stones worked by these men to come on the ground at Blackpool, or, being on the ground, as they now are, they will only fix them in case the firm will send no more, and will allow these to be reworked.

STAINED GLASS.

LAST week a window was placed in the south aisle of the parish church of Knaresbro', in memory of the late Mr. and Mrs. Powell. The subjects represented are the six corporal works of mercy mentioned in St. Matthew, 25th chapter, verses 37, 38, 39, and 40. The window has been designed and executed by Messrs. O'Connor, 4, Berners street.

The west window of the north aisle of St. Andrew's, Wells-street, has been filled with painted glass. The treatment is one of grisaille, with scarcely any colour. The upper lights are filled with angels playing upon instruments of music, and the lower ones with full-sized figures of King David, Miriam, the Blessed Virgin, and St. Simeon. Messrs. Clayton and Bell are the artists.

STATUES, MEMORIALS, ETC.

THE whole of the statues are now placed in their respective niches in the ornamental parade facing the Speaker's residence in New Palace-yard. These statues are placed in the following order, viz., Alfred the Great, William the Conqueror, Henry II., King John, Henry VIII., and William III. The two last were only placed on their pedestals on Tuesday week. These six statues have all been sculptured by foreign artists.

A memorial brass in the mediæval style, sunk in a slab of black Irish marble, has recently been placed in Elvaston Church, Derbyshire, to the memory of the late Earl of Harrington. The brass was executed by Messrs. Hart and Sons, of Wych-street.

NOTICES OF BOOKS.

An Elementary Course of Plane Geometry. By RICHARD WORMELL, M.A., Medallist in Mathematics and Natural Philosophy (London), author of "Arithmetic for Schools and Colleges." London: Thomas Murby, 32, Bouverie-street, Fleet-street, E.C.

IF the draught of knowledge could be rendered more agreeable to the mental palate than it generally proves, in all probability we should be a better educated people than we are. But it frequently occurs that, notwithstanding the valuable effects that are to follow the reception of the potion, the taking of it is attended with so bitter a taste that it is only the minority who have the courage to undergo the trial. At the present time the axiom still holds true that "there is no royal road to the acquisition of knowledge," but it will be nevertheless universally admitted that of late the "road" has been very much improved and its surface rendered smoother for the feet of the wayfarers. The author of the volume on our table has succeeded in investing the subject with a considerable amount of practical attraction, and illustrates each point by an appeal to the common sense of the student, in a manner that at once enlists his interest and arrests his attention. Lines and planes, angles, circles, and triangles are described in detail, and the T-square, the level, plumb line, and square introduced, to show the application they have to the rudiments of other branches of education, and how they bear upon many points of technical and professional training. At the end of every chapter a number of questions for self-examination are added, sufficient to enable the learner to fix, by means of their solution, the substance of the chapter in his memory.

Besides investigating the usual problems and examples occurring in plane geometry, considered solely with reference to figures, Mr. Wormell treats the subject in accordance with the strict meaning of the term, signifying the measurement of the earth. He illustrates the use of the surveyer's ordinary cross staff, by which lines or offsets are set off at right angles to the base or main lines,—gives briefly the principle of determining the relative level between any distant points. We think the "diagonal scale" might have been omitted, as it is entirely obsolete now, having completely been superseded by the more accurate and convenient plotting scales. The proportional compass and the pantagraph are also alluded to, and their use described. What is termed the oblique semi-oval, our engineering and architectural readers will recognise as the elevation of the arch of a skew bridge, the section of which on the square is a semicircle. The method given by the author will be found useful for drawing in the elevation when plotting a bridge design on the skew. Excellent rules are afforded for finding and delineating the curves of the Ionic volute, the involutes, and the figures of star polygons. These latter may be accomplished with equal facility either by reduction or extension. One of them, the star pentagon, is frequently used in ornamental work, and forms a prominent feature of what is called the Gothic rose. We consider this little volume to be well calculated, from its general style and method of treating the subject, to spread the knowledge of plane geometry among many who, for the reasons given at the commencement of this article, have hitherto held aloof from the study of that which they had been accustomed to regard as a distasteful and difficult branch of learning. A perusal of the first chapter will be sufficient to dispel this idea, and the farther the student advances the better reason he will have to be pleased with his task. In addition to the usual diagrams necessary to elucidate the principles and propositions enunciated in the text, there are a large number of drawings and cuts of the mathematical instruments alluded to, together with several very good examples of Gothic tracery and tesselated pavements, cornices, and mouldings. The type is clear and large, and each problem is stated previously to its demonstration, and printed in strong black letters, so as at once to arrest the eye. The whole get-up of the book is plain and unpretending, but exactly what is suited to its pretensions and the class of readers it will have especial attraction for, although it might be read and studied with advantage by every amateur tyro as well as professional.

The Mechanic's and Student's Guide in the Designing and Construction of General Machine Gearing, as eccentrics, screws, toothed wheels, &c., and the drawing of rectilineal and curved surfaces, with practical rules and details. Edited by FRANCIS HERBERT JOYNSON, author of "The Metals Used in Construction." Edinburgh: William P. Nimmo. 1868.

THE "gearing" of wheels, and the manner in which "racks," "pinions," "levels," and "spurs" act so as to transfer and communicate motion in various directions, and at almost any distance, is always a fruitful source of bewilderment to those who commence the study of mechanical engineering. Yet all the movements, no matter in what direction or of what order of curve they may belong to, can be accurately defined and set out on paper previously to the erection of the machinery. In fact, the correct delineation of the proper curves, the form of the teeth, their pitch and number, must be all precisely ascertained before the patterns can be made for the use of the foundry shop. The little work before us consists of a selection of practical problems bearing upon the handicraft of the mechanical engineer and the millwright. The majority of the numerous combinations that prevail in the practice of mechanics, and to which is to be attributed the almost marvellous effects produced, are worked out by diagrams and drawings made to scale, so that the student and beginner can trace every successive step by which the desired result is obtained. Chapter IV. will be found particularly interesting and instructive. It contains details and calculations connected with shafts, pulleys, and pedestals, together with several tables for facilitating the determination of their dimensions and effecting a saving of time and labour. We are glad to observe that the author recommends the adoption of wrought-iron shafts rather than cast. The violent strains of torsion to which large and heavy shafting is liable render it almost necessary that a less brittle and more reliable material should be chosen for the purpose.

In computing the diameters of shafts, the horse-power of the engine working them and the number of revolutions that the shaft has to make per minute must be given as the principal data for the calculation. All shafts may be divided into two classes—prime movers and secondary ones. The former are connected directly with the engine or other motive power, and the latter derive their motion from the former. Putting C for the constant, D for the required diameter, H the horse-power of the engine, and R the number of revolutions per minute, we have $D = C \times \sqrt[3]{\frac{H}{N}}$

This rule is generally applicable, but the value of the constant C varies. In wrought-iron prime movers it is 7; for wrought-iron secondary shafts it is 5·25; for cast-iron prime-mover shafts it is 7.5, and for cast-iron secondary ones, 6. Probably steel will come into extensive use for heavy shafting, not so much on account of its more power to transmit motion with a less amount of material, but for the superior resistance it offers to a strain of torsion. Supposing the same work were required to be done by a couple of shafts, one of which was of wrought-iron and the other of steel, then the diameter of the former being represented by unity, that of the latter would be equal to 0.86. As the diameter of the steel shaft is smaller than that of the iron one, its weight will also be less. Their relative weights will, in fact, be in the proportion of $(1)^2$ to $(0.86)^2$. There is another advantage that is possessed by steel over iron in this respect. It is in a very great diminution of friction between the rubbing surfaces. If unity represent the power necessary to overcome the friction of a wrought-iron shaft, then 0.625 will be a fair estimate of that required in the case of steel. The absolute strength of the two metals to resist a transverse strain is nearly equal, there being a trifling advantage in steel, but not amounting to more than about, on an average, two per cent. A chapter upon the geometrical problems likely to be of service to the mechanical draughtsman and designer brings the work to a close. Many of these are to be found in the ordinary treatises upon that particular branch of art, especially in those we have lately reviewed in the columns of the BUILDING NEWS. At the same time a few have been introduced possessing no especial interest for any persons except those intending to become mechanical engineers and millwrights. There are eighteen diagrams and plates attached to the volume, some of which are drawn to scale, and the whole are highly illustrative and explanatory of the contents of the text. We are of opinion that Mr. Joynson's little book will be found of great use in the drawing office, where calculations are always in progress for ascertaining the proportions of wheels, shafting, pulleys, plummer-blocks, and the numerous other details of mechanical appliances both on a large and a small scale.

RAILWAY ITEMS.

IN addition to the proposed new metropolitan railways referred to in our two last numbers, plans have been lodged in the Private Bill Office of the House of Commons for the following schemes:—A new underground railway from the southern end of London Bridge to Clapham Common, which will be for the entire distance under the highway, and will be provided with numerous ventilating shafts; a new line to be called the "Metropolitan and Islington," extending from the Metropolitan line in Clerkenwell to Cloudesley-road; and a new "Eastern Metropolitan Underground" line, from the City to the East, viâ Whitechapel and the Mile-end Road. The works of the Waterloo and Whitehall line on the pneumatic system, carried under the Thames in an iron tube, which have so long been stopped, are to be revived, and a bill has been lodged for the extension of the line from Waterloo Station to the Elephant and Castle.

The promoters of the new Brighton line are sanguine of the success of the undertaking, should the bill pass. There are only two tunnels on the line, one at Gipsy-hill, 187 yards long, and one near the point where the line will cross the Reading branch of the South-Eastern Railway. The gradients are easy throughout, nine-tenths of the route being on level reaches, and the curves are all on long radii. There are no viaducts on the line, and no embankments worth mentioning. The Brighton station will be near the Pavilion, on a low level. The cost of the line is estimated at one million and a third sterling. The promoters propose to insert in their bill their maximum fares, which, being moderate, will make the line a popular one.

On Thursday week the directors inspected that portion of the Metropolitan District Railway between Brompton and Westminster Bridge, which is now nearly completed, and will be shortly opened. Messrs. Kelk, Waring Brothers, and Lucas are the contractors.

Our Office Table.

It is believed that one of the first measures to be introduced into the new Parliament will be a bill altering the constitution of University College, and enlarging its objects so as to include the promotion of the fine arts.

The question as to whether the decision of the Metropolitan Asylum Board in respect of the plans for the Hampstead Hospital was fairly arrived at it is likely to come under the notice of the law courts.

Messrs. Christie, Manson, and Woods have received instructions to sell the property of the late Sir Charles Eastlake, P.R.A., on Monday next. The magnificent art library, however, which was formed by Sir Charles with great labour and zeal, is not to be dispersed, the trustees of the National Gallery having arranged to purchase it. The public will thus have the opportunity of consulting the many and rare works contained in it.

At the last meeting of the Academie des Beaux Arts M. Charles Blanc was elected to fill the vacancy caused by the death of the Comte Walewski. At the same meeting the honorary membership vacant by the death of Dr. Waagen was filled by the election of Mr. Charles Perkins, a well-known American writer on art, and author of "Italian Sculptors, being a History of Sculpture in Northern, Southern, and Eastern Italy," and of "Tuscan Sculptors."

The Liverpool Corporation recently purchased a steam roller for the purpose of levelling and smoothing newly-made and mended roads. In that capacity the monster (locally known as the "demon crusher") has been a great success; but it is reported to have so injured the network of gas and water pipes in the streets in which it has been used that the corporate authorities have determined to greatly decrease its weight or cease using it altogether.

Mr. Graves, the well-known printseller and publisher, has just prosecuted a person named Solomon Alber, of Great Prescott street, Whitechapel, for pirating his copyrights by means of photography. According to the police reports, Mr. Graves is made to say that "the painting and engraving of the 'Railway Station' cost him £24,000." This, says a contemporary, is a statement needing considerable qualification. It appears that a person now dead, who made the matter one of pure speculation, succeeded with a great outlay of time and money, in getting many hundreds of people to subscribe to the plate. In the aggregate the promises to take impressions amounted to very nearly £18,000 or £20,000. It was for the subscription book, with the picture and plate, that Mr. Graves paid his money. This puts a very different face on the matter.

Hackney Union, says the *Parochial Critic*, has had a piece of luck. They have found an architect who will increase the accommodation in their workhouse at Homerton, from that for 108 able-bodied paupers up to 350, including dormitories, day-rooms, work-rooms, at a cost of not more than £30 per head for the new building, and £6 per head for the alteration in the old; the total cost being £7,900 or £8,000. Contrast this with the £50,000 and £60,000 expenditure, and the rate of £60, £70, and even £80 per head called for by the Poor Law Board in some of the metropolitan parishes. The name of such an architect deserves to be chronicled. It is Mr. Lee; and if we remember rightly the Poor Law Board recommended him to the Hackney Guardians. Would that they could find a Mr. Lee for every parish!

Mr. Barkentin, says the *Ecclesiologist*, has in hand, from the designs of Mr. Burges, a new chalice for St. Andrew's, Wells-street—the gift of an anonymous contributor. On the base of the chalice will be six large medallions, representing respectively the Crucifixion, the Blessed Virgin, St. John Evangelist, St. Andrew, the Annunciation, and (on the sixth) a fragment of that gilded glass, of early Christian date, of which some rare specimens have from time to time been found in the catacombs. This fragment is the gift of Mr. Burges. The knob will have six enamels, representing the Four Rivers of Paradise, and the Tree of Life and the Tree of Knowledge. The bowl will be encircled round its base with eight enamelled medallions, all being types of our Lord from the animal creation: viz., the Agnus Dei, emblem of His Innocence; the Pelican, emblem of His meritorious Death; the Lion, emblem of His Resurrection; the Eagle, emblem of His Ascension; the Antelope, emblem of His loftiness of soul; the Phœnix, emblem of His new Life; the Ox, emblem of His Sacrifice; and the Swan, emblem (by its dying song) of the voluntariness of His Death.

The Municipality of Vienna have resolved upon the erection of a new townhall, and invite architects of all nations to send in plans conformable with certain regulations which are to be obtained from the Austrian Consul-General in Paris.

The other night the tower of St. John's Church, Goole, was burnt out, as was the transept underneath, including the pulpit and desk. The fire was owing, it is believed, to the defective fitting of a "sunlight."

We regret to notice that the "Ecclesiologist" is to be discontinued. That periodical has now been in existence nearly twenty-seven years, and in conjunction with the Ecclesiological Society has done good suit and service for art. In concluding with natural regret their final number, the editors state that it is abandoned now because higher duties claim the less divided attention of those who have conducted it from its commencement to its close.

With regard to placing trees and shrubs near our public buildings, there is a curious example in what may be called the grand front in Pall Mall, of that anomalous structure, St. James's Palace. There is a place fenced off with common area railings, and paved. This is now decorated with three scrubby shrubs, in odd tubs and pots, very probably placed there by the messenger under whose windows they are. In France there would be some architect of the palace who would prevent the spontaneous growth of abnormal excrescences, and who, if plants were wanted, would obtain them from the palace gardens. Next year perhaps a few orange trees will replace the shrubs and relieve the brick wall.

In addition to the £250,000 bequeathed by Mr. Peabody for improved house accommodation for the poor of London, he has now granted an additional £100,000 for the same purpose, making in all the unprecedented sum of £350,000. What else Mr. Peabody means to do he has not said But it now appears that his last gift was, as he says, "in pursuance of an intention which I have entertained since the creation of the fund." Who knows but what he means to make it half a million sterling. When it is borne in mind that Mr. Peabody has been granting similar sums for similar purposes in America, it will be admitted that he occupies the highest place among the merchant princes of the world who have bequeathed benefactions for the benefit of the poor.

Something of the noble spirit of the mediæval artists is to be found in Dr. Manning's recent utterances respecting the new Roman cathedral in Westminster. It was natural for men to ask when the building would be finished, and if there would be a probability of its consecration by Dr. Manning. The archbishop says—"I hope not, for if the cathedral were to be finished in my day it would not be a metropolitan church worthy of England." The grand style in which Dr. Manning works may be inferred from the fact that three acres of ground have been bought for the purpose at the West-end of London, and with an independent frontage on almost every side, at a cost of £36,000. The building is to be constructed upon the largest proportions of scale, and in the Early English style, as "a sound judgment prevails in favour of grandeur, stateliness, solidity, spaciousness, and majestic elevation." If Dr. Manning's grand resolve is steadily maintained, art and religion will have once more combined to produce a noble result.

The forty-first annual report of the Council of the Royal Scottish Academy has been issued. The Council congratulate the Academy on the marked increase in the prosperity which, during their term of office, has rewarded the labours of the institution. The last exhibition is stated to have been the most successful ever held by the Academy both as regards the number of works sold and the number of visitors. The sales amounted to £7,000, being an increase of £1,000 on the preceding year.

It is calculated, on pretty accurate data, that the quantity of granite quarried annually in Aberdeenshire is upwards of 80,000 tons, and of that nearly 40,000 tons are exported. The number of tons of granite exported from Aberdeen from 1840 down to the beginning of 1868 were:—1840, 25,557; 1850, 30,385; 1860, 24,666; 1865, 32,023; 1867, 43,790; 1868 (to 30th September), 31,600.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Society of Engineers.—The annual general meeting, 7.30.
Royal Institute of British Architects.—"Notes on the Celtic, Roman, Moorish, and other Architectural Remains in Algeria," by Professor T. H. Lewis.
Geographical Society, 8.30.

TUESDAY.—Institution of Civil Engineers.—"On Machines employed in Working and Breaking down Coal, so as to Avoid the use of Gunpowder," by Mr. Samuel Parker Bidder, jun., Assoc. Inst. C.E., 8.
Anthropological Society, 8.
Statistical Society, 8.

WEDNESDAY.—Society of Arts.—"On Artificial Freezing," by Dr. B. H. Paul, 8.

THURSDAY.—Linnean Society, 8.

Patents for Inventions

CONNECTED WITH THE BUILDING TRADE.

748 C. SCHOLEFIELD. HANGING WINDOW SASHES. Dated March 4, 1868.

This invention consists in connecting the sashes by means of two cords (or other pliable material), hereafter called the suspender, being attached to a top corner or some other part of each sash. Each suspender is then passed over a pulley or pulleys, shoe or shoes affixed over each sash. By this arrangement one sash balances the other in all positions, so that, when either the higher or lower sash is pulled down or raised up, the other sash ascends or descends a corresponding distance.—Patent abandoned.

777 J. EASTWOOD. MACHINERY FOR PREPARING SIZE. Dated March 6, 1868.

This invention relates, first, to the "dashers" employed in the washing of flour in the preparing of size, and consists in constructing such dashers or square shafts with a pair of flanges or collars thereon, betwixt which is received the fork of a lever working on a fulcrum; this lever is for the purpose of raising and lowering the dashers, as required, or, where convenient, pulley blocks may be employed. Second, to further improvements in the apparatus employed for heating and boiling size or other glutinous compounds, for which letters patent were granted to the present patentee in the year 1865 (No. 2883).—Patent completed.

801 F. J. BAYNES. KITCHEN RANGES. Dated March 7, 1868.

According to this invention, the inventor claims, first, in the mode of arranging bars of kitchen ranges, or other cooking stoves, to be actuated so that they may be capable of being turned at one time into a position to form part of the front of the fireplace, and at another time of being turned up to reduce the size of the fire as well, and in supporting it, substantially as described Also in the application of supporting, or bottom, bars to kitchen ranges in position at or near the line of the flue passages under the top plate, to the oven and boiler as stated. Second, the arranging kitchen ranges with boilers *m* and *n* to be heated in manner, substantially as described. Third, the arranging ash pans with screens or sinder sifters, substantially as explained.—Patent completed.

810 Lieutenant Colonel A. F. BAIRD. EARTH CLOSETS. Dated March 9, 1868.

This invention has reference to improvements applicable to earth closets, and is a further development of the invention patented by the present patentee, dated August 15, 1867 (No. 2351.) As in the former arrangements he has a hopper for supplying the earth to a shoot or valve or flap box, and a weighted flap or valve working therein, whereby the deodorising earth is supplied to the receptacle for excrementitious deposits; but in lieu of the arrangements for putting the closet into and out of action, described in the specification above referred to, he adopts the following arrangements:—He makes the weighted flap or valve (which is to move on its pivots or axle having bearings in the shoot or valve box) with its weighted portion at a right or other angle to the non-weighted portion, which latter has a part or projection thereof or therefrom so curved or formed that, being of sufficient size, it shall act as a flap or valve for closing the entrance from the hopper at the same time that the weighted portion is, leaving open the entrance from the shoot or valve box to the receptacle for deposits, by which new arrangements the valve or flap itself can thus be provided with a cavity or portion into which the dry earth is to be received from the hopper, and discharged by the action of the mechanism into the receptacle for excrementitious deposits, and thus also act as a measure for measuring out a sufficient quantity of dry earth at each action, and no more. At the angle at back (though any other convenient position may be adopted), another smaller projection is provided, so that, by having a rod or rail attached to the seat of the closet by means of side pieces or portions of the seat (which is to be a moving seat, as in the arrangements formerly specified under the patent above referred to), such seat will cause the flap or valve to open the hopper to the shoot, and the shoot to the receptacle for deposits, as may be required.—Patent completed.

Trade News.

TENDERS.

DERBY.—For sewering and completing Dashwood and Belgrave streets, Derby. Mr. George Thompson, borough surveyor, engineer:—

Tomlinson	£448
Thompson	425
Harpur	423

FINSBURY.—For erecting warehouses in Ropemaker-street, Finshury, for Messrs. Bartholomew and Son. F. G. Widdows, Esq., architect. Quantities supplied:—

Enoor	£6197
Webb and Son	6130
Chesham	5794
Colls and Son	5684
Bishop	5650
Newman and Mann	5586
Pritchard	5557
Henshaw	5347
Brass	5329
Browne and Robinson	5280
Kilby	5227
Hill, Keddell, and Waldram	5196

GONSTONE.—For erecting new Infirmary, &c., Godstone Union. Mr. A. R. Stanning, architect:—

Knight, Dover	£3900
Morris, East Grinstead	3899
Worsell, Oxted	3891
Cooper, Banstead	3600
Galyer and Moore, Godstone	3550

Williams	1740 0
Wise	1740 0
Pethick	1700 0
Hughesdon	1650 0
Bridel	1435 0
Heaysman	1388 10

STOKE-ON-TRENT.—For converting the old schools of the parish workhouse into hospital wards for imbeciles:—

Sutton	£736
Peace (accepted)	580

TONBRIDGE.—For erecting new Wesleyan schools at Tonbridge. Mr. Baker, architect:—

Wheatley	£798
Punnett	770
Woodroffe	760
Dove (accepted)	750

TOTTENHAM.—For erecting 44 almshouses, chapel, and lodge, with boundary walls, drains, &c., for the Worshipful Company of Drapers, at Elmslea, Tottenham, Middlesex. Mr. Herbert Williams, architect. Quantities supplied by Mr. Charles Reilly:—

Trollope and Sons	£15,989
Brass	15,667
Piper and Co.	15,391
Couder	14,997
Barnsley and Sons (Birmingham)	14,670
Ashby and Sons	14,165

COMPETITIONS.

INDIA.—Public Works' Department.—Competitive examinations for forty appointments in the Engineer Establishment in the month of December next. W. T. Thornton, India Office.

SOUTH METROPOLITAN SCHOOLS, SUTTON (Surrey).—February 2.—For designs for the erection of an infant establishment adjoining the present schools. Premiums of 40 guineas each for the three designs considered the best. J. Burgess, clerk to the managers, Vestry Hall, Walworth.

HARTLEY, WINTNEY, HANTS.—December 20.—For plans and specifications for the erection of a new church for the accommodation of about 700 persons. Mr. Wetherell, Hartley Wintney, Winchfield, Hants.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

HAMPTON COURT AND WALTON BRIDGES.—December 16. Tender for tolls. Mitre, Hampton Court.

LEWISHAM.—For the construction of six houses.—W. C. Banks, architect, 39A, Gracechurch-street, City.

CROYDON.—For about 2,000ft. or 3,000ft. of York paving. Mr. T. L. Robinson, High street, Croydon.

ST. GILES'S, CAMBERWELL.—December 21.—For the re-erection of Taylor's Bridge. G. W. Marsden, clerk, vestry hall.

DERBY.—December 14.—For the woodwork and roof for carriage shed at Derby Station, and for additional offices at Leicester. J. Moore, secretary pro tem., Midland Railway, Derby.

NEWCASTLE-ON-TYNE.—December 16.—For lighting the barracks with gas. Colonel W. G. Hawley, R.E. Office, Manchester.

STRATFORD.—December 7.—For lighting and warming the new townhall. C. Wilson, Rokeby House, Stratford.

UPPER MOOR, BODENHAM, HEREFORDSHIRE.—For the erection of new farm buildings, and alterations to farm house. F. R. Kempson, architect, 34, Castle street, Hereford.

ARSLEY, NEAR BIGGLESWADE.—December 18.—For alterations and additions to the vicarage. W. Watson, Esq., surveyor, Henlow, Biggleswade.

PROPERTY SALES.

NOVEMBER 30.

AT THE MART.—By Mr. Murrell.—Leasehold six houses, partially built, situate in Malvern road, Cambridge road, Kilburn Park, term 99 years from 1864, at £8 8s. per annum—sold for £160.

Leasehold residence, No. 8, Arlington street, Piccadilly, term 3½ years unexpired, at £80 per annum—£300.

Leasehold five houses, Nos. 1, 2, 5, 6, and 7, Ainger terrace, Ainger road, St John's wood, annual value £325, term 99 years, from 1862, at £9 each per annum—£500 to £530 each.

DECEMBER 1.

At the Mart.—By Messrs. Glasier and Sons.—Copyhold two cottages, Nos. 1 and 2, The Vineyard, Mortlake, producing £18 12s 8d. per annum—£150.

Freehold residence, known as Lasswade House, Westwood Park, Forest Hill, let on lease at £106 per annum—£1,560.

Freehold house and shop, No. 16, New street, Covent Garden, let on lease at £105 per annum—£2,040.

By Mr. Frank Lewis.—Leasehold premises, No. 173, Fleet street, term 21 years from 1857, at £140 per annum—£120.

Leasehold premises, No. 55, Exmouth street, Clerkenwell, let at £60 per annum, term 47 years unexpired, at £8 per annum—£450.

DECEMBER 2.

By Mr. Saffell.—Freehold house and shop, No. 4, Union terrace, Commercial road East, let at £70 per annum, and a building in the rear in Caroline street, let at £20 per annum—£1,370.

Leasehold two houses, Nos. 1 and 2, Paddington road, Westbourne Park, term 95 years unexpired, at £15 per annum—£635.

Leasehold two houses, Nos. 1 and 2, Blagrove road, Paddington road, annual value £33 per annum, term 95 years unexpired, at £7 each per annum—£485.

By Messrs. Prickett and Son.—Freehold plot of building land, situate at Finchley—£85.

Freehold plot of land, situate at Finchley—£87.

Freehold plot of land, situate at Finchley—£56.

Freehold plot of land, situate at Finchley—£20.

Freehold building land, situate in Chetwynd road, Kentish Town and Upper Holloway, in 16 lots:—Lot 1, £92; lot 2, £80; lot 3, £87; lot 4, £90; lot 5, £90; lot 6, £88, lot 7, £269; and lot 13, £89.

DECEMBER 3.

At the Mart.—By Mr. G. B. Houghton.—Freehold two residences, known as Isabel cottages, Nos. 4 and 5, Pemberton road, East Moulsey—£585.

By Messrs. R. and J. E. Low.—Leasehold stabling, No. 4, King's Arms yard, Glasshouse street, Regent street, let at £40 per annum, term 23 years unexpired, at a peppercorn—£325.

Leasehold stabling, Nos. 2 and 3, King's Arms yard, Glasshouse street, Regent street, term 14 years unexpired, at £81 per annum—£105.

By Mr. W. H. Moore.—Leasehold three houses, Nos. 12, 19, and 20, Georgiana street, Camden Town, let at £36 per annum each, term 72 years unexpired, at £4 each per annum—from £400 to £425 each.

Leasehold house, No. 33A, Cardington street, Hampstead road, let at £45 per annum, term 24 years unexpired, free from groundrent—£435.

Freehold house, No. 27, Cardington street, let at £45 per annum—£730.

Leasehold house, No. 89, Charrington street, Camden Town, annual value £60, term 81¼ years from Michaelmas last, at £5 per annum—£6.5.

Leasehold house, No. 101, Ossulston street, Euston road, let at £40 per annum, term 12 years unexpired, at £3 10s. per annum—£205.

Leasehold improved groundrent of £7 per annum (for 53 years) arising from No. 21, Roberts mews, Hampstead road—£100.

Leasehold improved groundrents of £11 10s per annum (for 80¼ years), arising from No. 1, York place, York road, Wandsworth road—£2 0.

Leasehold two residences, Nos. 34 and 35, Rochester road, Camden road, Camden Town, producing £95 per annum, term 50 years from 1854, at £12 per annum—£990.

Leasehold house and shop, No. 4, Aberdeen place, Stoke Newington, let at £55 per annum, term 50 years from 1863, at £10 per annum—£450.

At Garraway's.—By Mr. Fairbairn.—Freehold estate, comprising about 2¼ acres of land, with plant and machinery, situate at Buckhurst hill, and known as Watkins's Patent Steam Brick Factory—£1,900.

DECEMBER 4.

At the Mart.—By Messrs. Wilkinson and Horne.—Leasehold premises, No. 79, Lombard street, City, term 80 years from 1854, at £200 per annum—£13,500.

Leasehold premises, No. 90, West Smithfield, and No. 29, King street, Snowhill, term 17 years unexpired, at £125 per annum—£5,160.

DECEMBER 8.

At the Mart.—By Mr. Murrell.—Leasehold estates, comprising Esgairhir and Esgairfraith Lead and Copper Mines, in the parish of Llanfinangelgenewrglyn, in the county of Cardigan, together with buildings and plant, area about 1,3.5 acres, term 21 years from 1854, at a Royalty of 1-14—£540.

By Messrs. Owen and Jameson.—Freehold house, No. 2, Princes street, Rotherhithe, annual value £28—£235.

BATH STONE OF BEST QUALITY.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

Robert Charles Barbee, Wood green, builder, December 23, at 11—Edward Brown, Dale road, Kentish Town, builder, January 11, at 11—Robert Hammond, Liverpool-street, City, and Colville gardens, Notting hill, civil engineer, December 21, at 1—John King, Bloomfield road, Mile end, builder, December 18, at 11—Samuel John Longley, Great Dover street, Borough, builder, December 18, at 1—Alfred William Routledge, Millman street, Bedford row, and Hand court, Holborn, builder and cabinet maker, December 21, at 12—William Thomas Seal, Richmond, Surrey, builder, December 23, at 1—James George Surrey, East Greenwich, plasterer, December 29, at 11.

TO SURRENDER IN THE COUNTRY.

Robert Kirkwood, Newcastle-upon Tyne, plasterer, December 18, at 12—Henry Lees, Bardsley, engineer, December 21, at 11—George Peacock, Redfield, Gloucestershire, carpenter and builder, December 23, at 12—Robert Riches, Norwich, carpenter and cabinet maker, December 18, at 11—James Ashton, Woolton, near Liverpool, builder, December 14, at 12—John Bell, Stockton, joiner and builder, December 16, at 11—Henry Burrage, Brighton, plumber and glazier, December 19, at 11—John Caine, Hulme, joiner, December 17, at 9.30—John Hopwood Deady, Manchester, builder, December 16, at 11—John Tebbutt, jun., Rowell, Northamptonshire, builder, December 11, at 12—Thomas Witt, Stoke Damerel, engineer, December 14, at 12.30.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

January 14, J. Beale, Richmond road, West Brompton, builder—January 14, C. Wisher, Pitt street, Commercial road, Peckham, builder—January 18, C. Cornes, Hammersmith, carpenter and joiner—January 18, A. H. Angell, Chalvey, near Slough, builder—December 30, R. J. Jones, Liverpool, builder—January 12, M. Duckworth, Upper Pollard street, stonemason—December .., S. Cave, Tunbridge Wells, builder—January 22, H. Sharman, Lacemere, builder—December .1, G. Raves...ft, Crewe, builder—December 18, W. Brown, Hat...ley, plumber and glazier—December 2., W. E. ... Manchester, ... and builder—January .., W. J...s, Macclesfield, builder—January .., O. Davies, D...gely, builder.

PARTNERSHIPS DISSOLVED.

Buchanan and ...althard, D...ke street, Westminster, civil engineers—Farrar and D...t, Bradford, Yorkshire, joiner and builders—Lu...r and Co., Moorgate street and Birmingham, galvanised iron manufacturers—G. P...ck and G. Gibbings, Leyton, builders.

DIVIDENDS.

December 28, R. Harradine, ...e street, Edmonton, builder—December 18, F. Scurr, Darlington, joiner.

DECLARATION OF DIVIDENDS.

J. Abbot, Newton heath, near Manchester, joiner, div. 1s 9½d—J. Potts, Adswood, near Stockport, brickmaker, div. 6s 11d—Capner and Jones, Birkenhead, timber merchants, div. 3s 6d.

BANKRUPTCY ANNULLED.

Charles Robert League, Devonshire road, Wandsworth road, and Old Jewry, surveyor and auctioneer, November 30.

SCOTCH SEQUESTRATIONS.

William Summers, Glasgow, glazier, December 14, at 12—Frederick Smith, St. Andrews, glazier, December 12, at 12.

BREAKFAST.—A SUCCESSFUL EXPERIMENT.—The *Civil Service Gazette* has the following:—"There are very few simple articles of food which can boast so many valuable and important dietary properties as cocoa. While acting on the nerves as a gentle stimulant it provides the body with some of the purest elements of nutrition, and at the same time corrects and invigorates the action of the digestive organs. These beneficial effects depend in a great measure upon the manner of its preparation, but of late years such close attention has been given to the growth and treatment of cocoa that there is no difficulty in securing it with every useful quality fully developed. The singular success which Mr. Epps attained by his homœopathic preparation of cocoa has never been surpassed by any experiment list. Far and wide the reputation of Epps's Cocoa has spread by the simple force of its own extraordinary merits. Medical men of all shades of opinion have agreed in recommending it as the safest and most beneficial article of diet for persons of weak constitutions. This superiority of a particular mode of preparation over all others is a remarkable proof of the great results to be obtained from little causes. By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating round us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."

THE BUILDING NEWS.

LONDON, FRIDAY, DECEMBER 18, 1868.

THE ART OF EVERGREEN DECORATION TO CHURCHES AT CHRISTMAS AND OTHER FESTIVALS.

THE decoration of our churches at Christmas and other festivals is a custom that has grown rapidly, and has developed an art of some importance to the architect and decorative artist. From early Christian times it has been a habit, and a very pleasing one, to decorate or strew with foliage and flowers the tombs of the departed, and this appropriate and beautiful token of reverence could not have long been withheld from the sacred edifices themselves. Time-honoured though the custom must be, everybody knows what miserable displays of evergreens decked our churches a few years ago, when a few straggling sprigs of holly stuck into all the conceivable crevices and suspended from lamp-brackets and tie beams formed the meagre stock garnishing of our sacred structures. Mr. Edward Young Cox, of the firm of Cox and Son, ecclesiastical decorators, of Southampton-street, Strand, has just issued a work on the art under consideration,* intended to serve as a practical compendium on the subject for the guidance of the most inexperienced amateurs. The author professes to consider the subject æsthetically, and, without discussing the vexed question of the proper limits for ecclesiastical decoration, gives a variety of methods and designs that may at least be suggestive. Without commenting on the manner our author has fulfilled his task, we may simply say that he has wisely treated the art as one hardly yet systematised and defined, and has chosen rather to give a variety of methods and rules than to lay down any precise principles of his own.

Allusions gathered from numerous sources, and extracts from "Brand's Popular Antiquities of Great Britain," are interesting, and prove that both before and since the Reformation the practice of decking churches with foliage and flowers was sanctioned, and the usage extended to other festivals besides that of Christmas. Spenser, in his "Shepherd's Complaint," touches on the custom of garnishing the posts and "kirke pillars" with "hawthorne buds," "sweet eglantine," and "girlonds of roses." This allusion appeared in 1579. Stowe, about the same time, mentions the custom of dressing houses, conduits, and standards, as well as parish churches, with "holme," "ivy," "bayes," and other green gifts of the season of Christmas; and many other references and churchwardens' entries show that after the revision of our ritual, and during the sixteenth century, flowers and foliage were used for the same purpose both at the Nativity and at other festivals, as Palm Sunday, Easter, Whitsunday. As Mr. Cox observes, the corruption of the evergreen shrub "holly" from "holy" is significant of the antiquity of the usage. The citations are amply sufficient to show that this mode of commemorative decoration is not new, and has been applied to houses and secular objects as well as to our Christian sanctuaries.

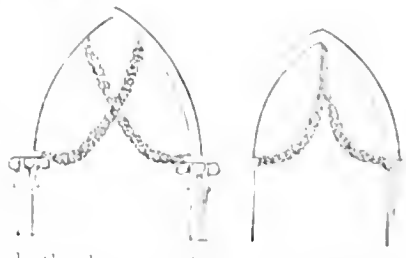
On the threshold of the subject we may stop to inquire, What should be the governing principles of such adornment? Should the architectural lines of the structure be followed as a basis, or should the ornamentation be placed quite irrespective of and at variance with it? The author takes Mr. Ruskin as his guide, and says, "An ordinary house decorator has no idea of colouring beyond that of 'picking' out the mouldings; and a large proportion of modern architects have not risen above this level of taste." Mr. Ruskin, in his "Seven Lamps," chap. IV., speaking of colouring, instances the stripes of a zebra, the leopard's spots, and the plumage of birds, to prove thereby that the variegation does not follow the anatomical and muscular systems, but is often opposed to them. He says, "Never paint a column with vertical lines, but always cross it." We cannot altogether agree with Mr. Cox or his authority. Ruskin's rule, "to simplify colour when form is rich, and *vice versa*," is certainly in favour of a *general* agreement of the constructive forms with the decoration; and, admitting the value of putting our decoration boldly on the plain or wall surfaces, we do not think the points of interest in form should be totally neglected, ignoring the unity and harmony of the two arts. Admitting even the analogy of nature we cannot see that purely conventional art should be subject to the same laws that govern the forms and adornments of the natural world, for it would be subjecting the reason of man to expect our decorative art to follow the markings on shells or the variegation of the animal world, especially its irregularities, as Mr. Ruskin would have us. We do not say, however, that the main lines and features of a structure should always be implicitly followed, but we contend they form the only reliable basis for decoration, or we sacrifice that homogeneity and connection so essential to the whole composition.

Beginning with the structure itself the decoration should be displayed along the nave walls or arcading, and Mr. Cox suggests two or three different modes of festooning or wreathing on the very applicable and simple principle of the catenary. A variety of effect can be produced in this way by considering the effects of suspending the wreath or trail from different points, and the method is at least inexpensive and easy, a great recommendation in these festive decorations. There is perhaps an objection to festooning, in a strictly-correct art sense; for our Gothic churches, it has rather too much of the Classic or Italian frieze character about it, and the suggestion of a series of equal festoons "all round the nave, either above the windows of the aisles or the arches," would certainly be open to the stricture. A double series of intersecting festoons is less open to the above remark, as also another variation, namely, a double series of festoons, the under one being suspended from the lowest points of

the upper series, as here shown. Better still, loops of foliage crossed at the ends.

We certainly prefer to follow the arch curves either by inserting into the hollows of the arch mouldings, or along the labels, bent splines or laths covered with foliage, to the method of Mr. Cox, namely, that of hanging large festoons across the arches below the openings

looped up with pendants in the spandrels. The lines of evergreen thus crossing the arch curves at nearly right angles cannot have a very pleasing effect, the opponent lines being too contradictory and sharp. A very pretty and much more effective manner of looping the festoons or wreaths would be to suspend them at the springings and apex of the arch or allow the two chains of evergreen to cross in the centre. The chancel arch might be thus treated.



In the chapter on the "Methods of Forming Wreaths of Evergreen" our author gives various ways of fastening the foliage. The most expeditious is to stretch the rope, which should be of the required length of the wreath, across the room at an easy height, and begin by disposing the sprigs of holly and bunches of berries round it, fastening with twine, and arranging the next bunches so that the stalks may be hidden, and tying a knot at every twist. The sprigs should be first assorted in heaps of different kinds, and bunches of berries inter-spersed through out the length. Instead of the twine, the twigs are better tied by fine copper or brass wire. The latter we recommend. Flat wreaths are preferred to round ones by some, and stout string or whipcord is a more pliable foundation for them than rope. For ladies, Mr. Cox suggests green worsted binding, the twigs, flowers, and berries being sewn on. This gives a broad, flat wreath, applicable for twisting round large columns. For foliated chaplets round capitals, "it is found a good plan to use a band of hoop iron with a hole punched in each end" for fastening by wire or string.

As there are generally deeply undercut members to capitals of pillars and always a necking, we prefer a simple wire or rope wreath to the above, which, at any rate, is troublesome if always obtainable at the moment.

The author recommends the use of yellow everlastings (*Anaphalium*) introduced here and there on the wreath in the same manner as holly berries, and they can be afterwards tied to the wreath at the most effective points. Several useful precautions are added for the benefit of wreath-makers—first, that all the leaves should be directed upwards; second, that the fewer nails or tacks used the better, to avoid injury to the plastering or stonework; and, lastly, that a sprinkling of water occasionally over the foliage will keep the wreaths fresh.

We cannot speak very favourably of some of the designs that illustrate this part of the subject. Festooning from capital to capital may be an easy but certainly not an artistic mode of adorning the nave; nor do we like the patches of surface foliage or diapering (shown in plate 2) partly filling up the spandrels, nor the tufts that, finial-like, crown the apices of the arches. The vertical trails hanging along the side walls are to our minds also unmeaning, and look too much like milliners' work; moreover, they would be apt to get disarranged. The trellis work formed of cross laths filled in with evergreen seems too heavy; but the cross diaper work shown on plate 1 or an evergreen trellising crowned with a cornice of leaves and berries or a flat band of foliage is certainly effective, and can be well and easily applied to relieve the wall surfaces below the springing of arches or between the windows. Of course the laths should be disposed diagonally in a Gothic building. A sparse sprinkling of leaves or a dotted appearance is always distasteful, and on this account we cannot approve of the dossel decoration formed of holly and berries tacked on in vertical lines. The design for a temporary reredos is weak and confused, and the sprigs of holly stuck at the summits of the arches are quite repugnant to Gothic taste.

For the columns or pillars we think the

* "The Art of Garnishing Churches at Christmas and other Festivals." By EDWARD YOUNG COX. With photographs, lithographs, and wood engravings illustrating the original designs of several architects, and numerous ancient examples. London: Cox and Son, ecclesiastical warehouse, 28 and 29, Southampton-street, Strand.

mode of adornment should much depend on the shape or section of them. A twisting wreath is simple and looks as well as anything. This may be crossed to form a diagonal diaper, as shown by Mr. Cox. For clustered shafts, or those quatrefoil on plan, we certainly suggest the vertical mode of decoration, or trails of evergreen inserted in the quirks or hollows. Laths covered with leaves would be better.

A simple diaper or diagonal lines of green forming a lattice pattern, just described, are the simplest modes of wall decoration. For the diapers the frame or groundwork can be made in various ways. For simple designs a lath or wire framework is the best; our author recommends perforated zinc as the best ground work, which should be cut out to the shape of the device, and the leaves and sprays of evergreens sewn on, beginning at the bottom of the device, the leaves being fastened across their veins, and the stalks overlaid by the next row. Everlastings are easily fastened to the zinc by passing the stalks through the perforations. Thin wood or thick cardboard we certainly prefer for small crosses, monograms, and devices, and the flowers or leaves fastened thereon with glue or thick paste. For devices fixed high up the larger leaves and the coarser workmanship suffice, but for those near the eye the small leaves should be used.

The east end of the church should, as our author observes, have the most lavish display, though we take exception to some of the designs, which show Mr. Ruskin's anti-architectural treatment. We do not pretend to follow Mr. Cox through his work, but he gives many valuable hints and directions for making monograms and devices with everlasting flowers and moss. "Natural flowers," he says, "should be provided with little zinc tubes filled with water, which can be soldered in any position, like inverted extinguishers, or hung by hooks." He also gives various modes of forming and emblazoning texts. Coloured paper cut to the shape and affixed to a ground of different tint is perhaps the simplest mode; evergreen borders can be put round the letters or text in a zigzag line, and bunches of scarlet berries placed at points. The plan usually resorted to of covering cardboard letters with evergreens and fastening them separately to the walls is objected to on the score of defacing the plaster or stone by tacks; but we think this objection could be overcome by placing the letters on a frame of wire or lath. "Prepared cloth," white glazed calico, coloured cloth, &c., are often substituted as a ground for the evergreen texts. A profusion of alphabets and lists of texts suitable for different seasons are given, not the least suggestive feature of Mr. Cox's handbook. It would be entering into the region of symbolism to discuss the variety and applicability of the devices that can be used to cover walls, the gallery fronts, &c. Individual circumstances and taste must do this.

Without going into the chapters on "appliqué work," and other means of church embroidery, worked and illuminated banners, etc., we will simply notice the features on which decoration may be applied.

Window sills, at least those that slope, are available for devices or simple texts, and these are well relieved on grounds of moss or evergreens. Connecting the sills by a band of evergreen, or by a continuous text, as "His name shall be called Wonderful, Councillor, the Mighty God, &c.," is a capital method of relieving the walls and forming a connection. Pulpits and reading desks may be garnished by simple wreaths tied or tacked round the top members or capping, and devices or symbolical designs introduced into the panels or faces. Lightness and delicacy are of course essential in these parts, being so close to the eye. Everlasting flowers worked in devices are pretty, and very applicable here. The font, as our author says, demands especial care at the festival of Christmas. He says, a floating floral cross made of board perforated with holes for the stalks of flowers, as white lilies, has a "beautiful and appropriate appearance." A leafy canopy made on an iron framework, and the sides of font festooned or ornamented with devices, constitute a very effective decoration, however; and the horizontal members and angles can also be emphasised by evergreen chaplets and bosses of red berries or everlastings. Lecterns, coronæ, and standards are all easily decorated by garlands, twisting wreaths round the stems, and the stem of font can also be relieved by a spiral wreath. Among the evergreens suitable for Christmas taken from an ample list in Mr. Cox's book are holly, variegated holly, ivy, laurel, box, yew, and arbor vitæ.

On the whole, Mr. Cox's book is a suggestive one, and the most useful and complete manual of the art we are acquainted with, though he does not say anything about the porch and exterior; to the former, at least, we should like to see the festal garnishing carried.

DRAINAGE OF TOWNS IN THE VALLEY OF THE THAMES.

IT will strike any one who has taken any interest in the manner in which the authorities have dealt with the subject of the purification of the Thames that, in order to effectually carry out the object of their remedial measures, it was necessary, not merely to forbid the discharge of the London sewage into the river, but of all towns situated higher up the stream. Some time back, therefore, an injunction was obtained by the Board of Conservancy to restrain the towns of Oxford, Eton, Windsor, and Abingdon from continuing to make the Thames their common sewer. To have summarily put into execution the "mandamus" of the court would have been a harsh and unwarrantable proceeding, and one which no donbt would have caused an appeal for a reasonable time to comply with the terms of the injunction. Accordingly a full year was granted to carry out the works indispensable for a proper diversion of the ordinary and hitherto used sewage channels. We now come to a portion of the history of the affair that it appears very difficult to account for. The local boards of the various towns concerned in the sanitary prohibition professed themselves either ignorant of the proper course to be adopted or unwilling to undertake the responsibility of acting promptly and decisively. In order, therefore, to shift the onus of the future operations upon some other shoulders than their own, they petitioned the Home Secretary to tell them how to get rid of their sewage, and extricate themselves from the dilemma in which they were placed. What appears difficult to account for is the circumstanee that had the boards consulted any eminent civil engineer, he would have given them a plan for effecting the desired object. Why did they not, like the local authorities of other districts, call in professional advice, and put themselves under the guidance and directions of a sound, practical man? As the matter stood, the Home Department listened attentively to the petition, and, after mature deliberation, appointed Colonel Ewart, R.E., to inquire into "the plans for the drainage of the several towns situated in the valley of the Thames, with a view to the purification of that river."

We question very much if Colonel Ewart was the best person to appoint to such a duty, as we are not aware that the Royal Engineers have had anything to do with extensive schemes of town drainage. That he has set about his task with all the ability and energy at his command there can be no doubt; but yet he can scarcely be regarded as an authority upon sewage plans. One very important point was secured by his nomination to the office, and that was the ensuring of a genuine disinterested report, where every project or proposal would be considered with regard to its absolute merits, and nothing else. As an officer of Engineers, Colonel Ewart would be unbiassed by any motives or considerations that might carry undue weight with a civil professional man, and his report is characterised by the absence of all partial statements or prejudicial views. The natural features of Oxford, Eton, Windsor, and Abingdon, and the extreme lowness of the valley in which they are situated, preclude the possibility of distributing the sewage by gravitation over more than a portion of the total area of land required. Consequently, pumping must be resorted to, in order to obtain command over the remaining portion of ground required to profitably utilise the sewage. This forms a great obstacle, owing to the expense it entails in the carrying out of a proper and efficient system of sewage and drainage. Nevertheless, it is high time that it no longer be so regarded. Every town promising or likely to possess more than ten thousand inhabitants must sooner or later adopt a plan of utilisation of its sewage, and as not one in twenty is so advantageously situated as to be able to apply the gravitation principle, the only other means of accomplishing the result is by having recourse to pumping. In the prosecution of the trust imposed on him, Colonel Ewart not only examined all the plans that were submitted to him, but visited the few localities possessing a system of sewage utilisation. It is scarcely necessary to state that Croydon was one of the places carefully inspected, together with Canterbury, Broadmoor, Aldershot, and Bedford. After fully investigating the merits of the dry earth system, and acknowledging that it is of value in small villages, barracks, hospitals, and outlying districts, the reporter decides that, in his opinion, it is not the best suitable for large towns, an opinion in which we concur. It is very succinctly remarked that the general use of earth-closets necessitates the general abolition of water-closets, which would be a very impracticable and unwise proceeding to take in towns where the latter are established and used by nearly all the better class of householders. We admit freely that great benefit has been derived in India and elsewhere by the partial adoption of the earth-closets in peculiarly situated localities, but at the same time consider them utterly unsuitable for the exigencies of a large city or town.

Having once determined that the principle of "water carriage" shall be that adopted for the conveyance of sewage, the next step is to inquire into the best methods of applying that principle. The questions that arise in connection with it are numerous. Is the rain water to be conveyed, also, in the same channels with the sewage, or are they to have separate means of transport? Is the sewage to be delivered upon the land, direct from the sewers—as at Lodge Farm, Barking? or is it to be disinfected and deodorised and run into the nearest water-course, as at Canterbury and Leicester? It is well known that complete failure has attended all the attempts undertaken with the view of purifying sewage by the use of chemical precipitants. There is a constant outlay for the purchase of the necessary drugs and reagents, and the result has been exceedingly unsatisfactory in every instance. In the opinion of Colonel Ewart, no chemical methods hitherto invented will purify the sewage of the towns in the valley of the Thames to such a degree that it could be discharged into the river without violating the Thames Navigation Act. The principle of "water carriage" may be divided into three heads—namely, the separate system, the mixed, and the joint system. The first of these does not admit of the introduction of the rain and surface drainage into the sewers that convey the sewage. The mixed system takes a portion of the surface drainage as well as the sewage in the same drain, but leaves another portion of the rain water to pass off by the natural channels. The joint system is that adopted by the Metropolitan Board of Works, and, therefore, requires no further description.

After a careful consideration of the merits of these three systems, Colonel Ewart decides in favour of the "separate system," a decision we by no means concur in. The objections raised in the report against the "London plan" are that accumulations of sand and fœcal matter form in the sewers, that their ventilation is defective, and that the sewage is so much diluted as to be of little use to the land. In answer to these, it may be stated that if the gulleys are properly made and properly trapped, the objections are not valid; that London is the most healthy city in the world, and that the results at Lodge Farm, Barking, leave no doubt of the fertilising powers of the London sewage. Against the "separate system" there are many and weighty objections. In the first place, two separate systems of drains and sewers must be constructed, which in itself is in many cases almost a direct prohibition, owing to the enormous expense that would have to be incurred. According to Mr. Bazalgette, to drain London upon the "separate system" would cost £12,000,000. It is true that in the towns under consideration, the old drains may be used for that purpose, but while this may effect a pecuniary saving in these particular instances, it is no argument in favour of the plan. In addition to the cost of an additional set of drains, the separate system entails considerable expense in the shape of reservoirs and settling tanks. It is absurd to imagine that surface drainage could be rendered clear and pure by "careful scavenging of the streets." The recommendations in the report respecting the ventilation of the foul sewers, the area of land to be taken, and other details, are all well known to sewage engineers, and call for no especial notice. Before adopting the principle of drainage advocated in the report we have alluded to, we would advise the local authorities of the towns in question to have a careful estimate prepared by a competent civil engineer of the cost of applying the "separate" and "joint" or "London system" of sewerage to their districts. If they once commit themselves and the ratepayers to a certain course, they will have no option but to proceed, no matter what the expense may be.

ASSOCIATED ARTS INSTITUTE.

AT the fortnightly meeting of this Institute, on Saturday last, Professor Westmacott, president, in the chair, Messrs. John Nicholas Parting, Frank Cox, and Charles Gliddon were duly elected members. After a few introductory remarks by the chairman—

Mr. Richard Redgrave, R.A., read a paper on—

THE TREATMENT OF SUBJECT IN PAINTING.

The choice of a suitable subject, said Mr. Redgrave, in his prefatory remarks, is one of the signs of a vocation for art, while the treatment of that subject when chosen indubitably marks the measure of a man's genius, and shows whether or not he is a true painter. Although, on cursory consideration, it would be thought that an extremely literal rendering of his subject by the painter would evince the truest treatment, it should be recollected that all incidents occurring in real life are *successive* in their action, while the painter is confined to a momentary representation of the incident chosen. While naturalness and individuality should not be overlooked, the painter must in a great degree render the qualities of the mind by nobleness of aspect or dignity of action. Paul said his personal appearance was mean, but was the painter to so represent the great Apostle to the Gentiles? Everything in a picture of real life or contemporary history should be in harmony with the event described. In treating the great events of past ages, much more the relations of poetry or fiction, great latitude taken by the painter may be used so as to bring home the truths of history or the inventions of the poet far better than a more literal rendering. Froude, in his "Science of History," says:—"The poet is not bound, when it is inconvenient, to what may be called 'the accident of facts.'" This truth applies equally to the painter, who, if allowed an equal control over "the accident of facts," will so dispose them as to present the greater truth on his canvas. In the best period of the art of the old masters compositions are found in which the canvas is filled up with mere spectators of the incident going on, themselves little moved [illegible] with the story; or, again, the composition is crowded with a host of individuals of the painter's own time, spectators of an incident it may be, of long past ages. Such is the "Building of the Tower of Babel," by Benozzo Gozzoli, on the walls of the Campo Santa, at Pisa. Another treatment adopted by the painter was seen in Leonardo's "Last Supper," where the Apostles are placed on one side of the table, the other side being unoccupied. This treatment is quite the reverse of a literal one, as the Oriental custom of reclining on couches at meals is totally ignored. Yet, in the hands of Leonardo how noble is the treatment! Such compositions were originally placed in refectories of monasteries, so as to make our Lord's table, as it were, the dais table, at which sat the nobler guests, the other tables being occupied by the monks themselves. A relation between the figures in the pictures and the spectator is obtained in some works by a figure or figures within the picture looking out to the spectator, or pointing to the action going on, and appealing by look or gesture to those without. This mode of treatment is exemplified by such works as the Madonna da Foligno, where, on one side, St. Francis looks at the Virgin, and points out of the picture as if imploring her regards for the people; while on the other side St. John the Baptist looks at the spectators and points to the Madonna, as if calling on them to pay adoration to her. Sometimes the principal figure is made to look pointedly out of the picture to the spectator, wherever he goes within sight of the figure. This effect, simply the result of the sitter looking at the painter during his work, has been made to appeal strongly to untutored worshippers in an ignorant age. Some painters have grouped together in one composition incidents completely remote in time and place, almost telling the tale of a life on a single canvas. Thus in the Pinacotha at Munich there is a picture by Memling of the "Seven Sorrows of the Blessed Virgin," depicting seven of the scenes in the life of our Lord which pierced with woe the heart of Mary. In many of the frescoes of the fifteenth century this treatment, somewhat modified, is adopted, as in the "Life of Abraham," and the "History of Job," by Gozzoli, in the Campo Santa, and in "The Calling of Moses," by Sandro Botticelli in the Sistine chapel. Incongruous as such treatments seem when described, they appear far less so when seen. Though they can hardly be justified, how happily has Raphael —who always availed himself of any license in art—worked out a succession of incidents in his noble cartoon of Ananias and Sapphira! Who can say in this case that an adherence to rule would have resulted in a composition equally grand and noble as that achieved by its infraction? In the painter's treatment of his subject he has to consider the local scenery of the action, the costume and the national character of the actors, and to determine, not merely what these are, but how he may make them tell on the feelings of the spectator. It would be a great outrage on the common sense of the spectator if an artist of our own day, in a painting of the taking of Magdala, were to depict the English general and his forces either naked or in a classic costume. Yet, even this treatment, absurd as it now seems, when set aside by Benjamin West in his picture of the "Death of Wolfe," in favour of a more literal rendering, was considered a great error in judgment on his part—an error which only his success justified. The question is widely different when the incident or action took place in times long past, and when the ideas of those to whom the painter appeals are quite unsettled or wholly at variance with the literal truth. When art revived in Italy in the middle ages, and was patronised by the church in the interests of religion, the knowledge of the East and its people was very limited, and the painters treated Scripture subjects with the costume and accessories of their own time. This treatment is seen in the fresco in the Campo Santa of "The History of Joseph," in which neither the sandy plains of the delta of the Nile nor the massive palaces of Egypt compose the background, but the lighter architecture and hilly scenery by which the painter was surrounded, while the children of Jacob are attired in the tabard coats, the tight hose, and the quaint caps of the fifteenth century. Such treatment may have had the effect of bringing the subjects more home to the feelings of the ignorant, but whether this was so or not, mediæval artists most frequently treated the facts of Scripture history in accordance with the habits of their own age and [illegible].

[illegible] the painters of the fifteenth and sixteenth centuries was the adoption of any [illegible] by their [illegible], arising, perhaps partly from the respect paid to works [illegible], but [illegible], Mr. Redgrave thought, to a [illegible] to carry on the art. They made no scruple of using the compositions of their predecessors, or in taking groups or single figures almost literally into their compositions. Thus Raphael adopted complete figures from the works of his master, Perugino, as in the picture of "The Marriage of the Virgin" at Milan, and both Raphael and Michael Angelo drew upon the works of Luca Signorelli and Massaccio. This custom conforms to the practice of the Greeks, who, in the best times, sought for perfection rather than originality, to improve on the works of their predecessors rather than to invent themselves. Thus, in architecture, the simple and severe Doric order was from age to age refined by them in proportion, though not altered in its details. Another treatment of the subject in painting which, when judiciously employed, is very impressive, is that wherein the main incident of the story is rather suggested than displayed, as in Paul de la Roche's "Two Children of Edward IV. in the Tower," and Sir Edwin Landseer's "Suspense." Mr. Redgrave, after a few remarks on the treatment of subject by the landscape painter, concluded his paper with a few general observations. In the treatment of any subject, he said, either as to its general effect or its accessories and details, the painter is not to be confined to the limits of the probable, but is allowed the freedom of the possible. He may combine objects not usually in relation to one another. Seasons and times may be interchanged if the object is to add poetry or sentiment to the scene. Each mode of treatment had its merits—the imitative, as a mode of study to lead up to that more general treatment which seized the spirit of the whole instead of forming an agglomeration of details. Though the artist should earnestly study nature, not only in its general aspect, but in its minutest details, by the separate and careful imitation of parts, these latter, as the hand gets practice and the mind acquires vigour, should be rendered wholly subservient to that general treatment resulting from the union of the poet's mind with the painter's hand.

The Chairman, in an able and somewhat lengthy speech, highly eulogised the paper read for the soundness of the principles inculcated in it, and a vote of thanks having been passed by acclamation, and responded to by Mr. Redgrave, the meeting adjourned.

WORKING MEN'S VIEWS ON ART SUBJECTS.

A MEETING of the Birmingham Society of Artisans was held at the Midland Institute, Birmingham, on Saturday night, Mr. Freeth presiding.

Mr. SWENE read a paper in which he directed attention to the principles or laws of ornamentation deducible from the structure of plants and animals. The most simple and perfect connection of lines in nature is by radiation, that is, by their all springing from one point or closing towards it; as the boughs of trees, though they intersect and fly amongst each other irregularly, indicate by their general tendency their origin from one root. An essential part of the beauty of all vegetable form is in this radiation, and it is carried out also in the [illegible] world. The law of radiation was well [illegible] to many nations among the ancients. [illegible] observed that "in the surface decoration of the Moors, all ornaments play out of a parent stem, and the eye is never offended, as in modern art, by the [illegible] introduction of an ornament without any reason for its existence." The same law is curiously connected with certain forms of Greek, Byzantine, and Gothic architecture. In a very few of the things manufactured in the present day the law is observed, but, as a rule, the branches of chandeliers, for instance, are stuck on anyhow, and the foliage on fenders sticks out all sorts of ways. Another law is that of repetition—one object or group of objects imitating or repeating another. This law, when carried out easily and freely—not formally and lifelessly—gives grace and power, but it is neglected in most modern manufactures, or else is replaced

by lifeless reduplications. The ancients had an eye for this natural law of repetition or imitation. Another law is that of alternation. The boughs of a tree, or the leaves on a bough, do not grow directly opposite each other, but they are arranged alternately on either side of the stem; or, if they have a circular arrangement, they grow out apparently at all points, but they are really arranged in a most orderly manner, not one being in the way of its fellow, but each one placed in the very best spot which could be selected for it, with a view to its freedom and welfare. These natural laws, which are so much neglected in this and other civilised communities, and the neglect of which has so debasing an effect upon our manufactures and such a deadening influence upon the taste of the community, seem to be carried out instinctively by some savage tribes. Every bit of ornament on the oar with which a South Sea Islander propels his canoe, so far from being a useless encumbrance, actually increases the strength of the oar, and the laws of radiation, repetition, alternation, and adaptation are obeyed as it were by instinct. This law of adaptation is one of the most important in the whole sphere of art manufactures. The necks of glass decanters are often seen ornamented with sharp "pin-headed" diamond-shaped figures, as if for the very purpose of threatening the hand that seized the decanter. How much better to flute the neck, which not merely makes it more agreeable to handle, but is much less expensive. He mentioned several instances of "adaptation" in nature. The ivy, when growing in an exposed situation, has its leaves arranged spirally all round the stem; but when it climbs up a wall, the leaves all grow on one side. The Greeks and the Egyptians knew well the value of adaptability, and carried it out with a degree of thoughtfulness and care of which few manufacturers or designers in these days had any notion. In England it was not rare to see dinner-plates with all the ornament in the centre, where it could not be seen, cut-glass decanters from which wine could not be poured without spilling it, and fireplaces with ornaments projecting so as to be positively dangerous. He saw some time ago in a working man's house a guard intended to keep the children from the fire. It was not a bow, but square. It was made of polished steel, and it was decorated at the corners with sharp spiral points sticking out at the children. This was the notion one intelligent artisan had of ornament and of suitability. One thing which should be constantly borne in mind was glanced at under the head of the law of radiation; that is, that ornament should not be merely laid on, but should grow out of, and form part of, the thing ornamented. The Egyptians made their columns representations of bunches of papyrus tied together, and their capitals were consequently, and naturally, and beautifully, the flowering of the papyrus. There was nothing superfluous, n thing to spare, nothing could be taken without injuring the whole; but with regard to English ornament, a great deal of it might be taken away with advantage. Some people imagine that beauty and utility are inconsistent, whereas beauty is the perfection of utility. Nothing can be beautiful which is not exquisitely adapted to its purpose. People deceive themselves very much who think they have a "beautiful" carpet because it is so expensive that they dare not walk upon it. The demand for technical education is an indication of revolt against the notion that useful things must or ought to be ugly. England must rise above that idea if she would maintain her place among the nations.

Mr. SARGEANT lamented that there was so much truth in the stricture of Mr. Swene upon English manufactures. He thought that one great cause of decline was the excessive division of labour. The engineer nowadays paid no attention to decoration, but put up bridges like that in Great Charles-street. On the other hand, the decorator paid no attention to construction, and, when he produced an article intended for use, it was very pretty, but failed to serve its purpose. This cause of failure, in his opinion, ran through the whole of English life—religion and politics, as well as manufactures. Take art. Morland was a man of such manual dexterity that he could paint anything his mind conceived; but having no poetry whatever in him, he only painted pigs. There were, on the other hand, men of poetic natures who could not reproduce on canvas what they were capable of imagining. The repelling and disorganised units of society required to be brought together and harmonised and directed.

Mr. SWENE observed, in confirmation of Mr. Sargeant's remarks, that the great artists of the fourteenth, fifteenth, and sixteenth centuries—Benvenuto Cellini, for example—had many-sided powers. They were acquainted not merely with one department, but with every province of their art. There was a thoroughness about them which could not be expected where men learned only to make a pin's head, and went on during a lifetime without knowing how to sharpen the point.

Mr. BARNES said another great cause of the inferiority of manufactures was that the masters had struggled upward without being educated for their new position. They knew the manipulative portion of the work, but for the rest, they went blundering on, and they did not fail utterly because if they did not know, neither did their competitors—in this country at least. The manufacturers of other countries knew, it seemed, and the English must now learn too, or else be beaten. With regard to the art training at the School of Design, he utterly abhorred the whole system.

Mr. LOWE, and one or two other gentlemen, made some observations, which brought the discussion to a close.

THE MANUFACTURE OF PAVING STONES.

THE *Scotsman* contains some useful information on this question. There are two counties in Scotland which produce paving-stones—Forfarshire and Caithness. The pavement quarries of Forfarshire are the oldest and most extensive in the kingdom. Of late years the trade has been very largely developed, and the number of workmen employed in it greatly increased, in consequence of the introduction of planing, cutting, and dressing machines. The planing-machine now in use in almost all pavement quarries was invented by the late Mr. James Hunter, of Leysmill, near Arbroath, who was for many years manager on the quarries belonging to the late Mr. Lindsay Carnegie, of Spynie and Boysack, and later to his son and successor in the estate.

During the last few years many improvements have been introduced in the manufacture of paving stones. The principal is the substitution of chilled cast tools for the steel tools first used. The chilled tools are at once cheaper and more durable. The machines, which are sent to all parts of the country where there are quarries, form a considerable article of manufacture at Arbroath. Had it not been for them, the pavement trade could never have attained its present dimensions. The larger of the cutting-machines consist of enormous masses of iron. The cutting is done by means of tools placed in revolving discs, and great slabs of stone are cut through or split up with as much ease as if they were pieces of cardboard. The dressing-machines are used for dressing stair-steps, coping, and much of the general mason-work still commonly done by manual labour.

The Forfarshire pavement quarries, which these machines have been largely instrumental in making famous, extend from Leysmill, in the east, which is situated about three miles inland, to near the fine old castle of Glamis, in the west—a distance of about sixteen miles. From north to south, they stretch from Montrewmont Muir to the Sidlaw Hills—about twenty miles. The quarries are thus all situated in the southern or more lowland portion of the county. The pavement produced throughout all this district, as well as that worked in the near neighbourhood of Arbroath, is known in commerce as Arbroath pavement. The stone is a freestone, and is found in the lower beds of the Devonian or Old Red Sandstone formation. It is solid in composition, and therefore very durable, but is easily worked and dressed. It is extensively used not only for paving streets out for all inside work of houses and other purposes.

There are very many quarries in Forfarshire, the principal being the Carmylie Quarries, where there are 300 men constantly employed. The machinery consists of eight planing machines, several cutting machines, eight saws for jointing pavement, one machine for making steps, coping, and tabling; two polishing-machines, six steam-engines, and from twelve to fourteen steam and other cranes. The quarries turn out almost any weight or size of stones—stones weighing 20 tons and measuring 200ft. superficial. The large stones are suitable for calender works and similar establishments where great stone tables are required. Many of these stones have been sent away from the quarries of late. The Carmylie stones are famed over the world as paving, and for steps, cisterns for paper makers, chemical works and bleachfields, columns, balustrades, and other architectural ornaments. For these and similar purposes they are widely exported to the various cities of the United Kingdom, to many countries in Europe, to the United States, Australia, and the colonies generally. Many towns in Scotland are paved with Carmylie stones. They have been, or are being, used as paving, steps, copes, &c., at a large number of public buildings—such as the new Glasgow College, the New College, Edinburgh; the Bank of Scotland, Edinburgh; Craiglockhart Poorhouse; the new markets, Edinburgh; the extensive works of Baxter Brothers, Dundee; The Denburn Railway station, all the principal buildings in Aberdeen; the Perth railway station, &c. The weight of stones sent away from the Carmylie quarries daily is about 150 tons.

The Caithness flagstones, the working of which represents a considerable part of the industry of the county, belong to the middle formation of the Old Red Sandstone. Great numbers of fossil fish and plants are found intercalated amongst the flag-beds of commerce, having been buried in the ancient mud of the Old Red waters. These fossils are a marked feature on almost every slab of Caithness pavement. Although the fish remains lie by thousands, it is seldom that anything like a perfect specimen is got. However, they are beautiful in their ruin—their blackened, enamelled, and glistening scales and plates standing out in contrast with the sober grey of the matrix. The flag-beds have suffered much in geological ages from dislocations by "faults" and other causes.

The geological character of flagstone having, of course, a close relation to the commercial and industrial value, it may not be out of place to quote what an eminent geologist states concerning the flagstones of Caithness. In his "Siluria," Sir Roderick Murchison says:—"The flagstones of Caithness are in many places impregnated with bitumen, chiefly resulting from the quantity of fishes embedded in them. Their most durable and best qualities as flagstones are derived from an admixture of this bitumen with finely laminated silicious, calcareous, and argillaceous particles, the whole forming a natural cement more impervious to moisture than any stone with which I am acquainted." Sir Roderick then gives analyses of several specimens of flagstone and the accompanying bituminous shales from Mr. Traill's quarries at Castlehill, and considers that they are of "high value, having been prepared by that distinguished chemist, Dr. Hoffman." These analyses are as follow:—

Mineral analysed	Silica and Silicates insoluble in H.O.	Oxide of Iron and Alumina.	Carbonate of Lime.	Organic Matter.	Water loss at 100 C.	Salts of magnesia, the alkalies, &c.
No. 16, top flag ...	68.40	10.21	10.93	3.88	0.42	6.16
No 7, middle flag	69.45	11.50	10.66	5.79	0.40	2.20
Bituminous shale	69.96	8.15	7.72	10.73	0.53	2.91
No. 1, bottom flag	61.69	4.87	21.91	3.40	0.20	8.23

Sir Roderick adds:—"These results completely sustain the opinion I was led to form on the spot, that the peculiar tenacity and durability of the flagstones is due to the manner in which silica and alumina are cemented together by certain proportions of calcareous and bituminous (organic) matter."

A portion of bituminous schist got near Barrogill Castle, Dr. Hoffman reported yielded—of fixed matter (mineral), 70 parts, and of volatile matter (organic), 30 parts. In time, probably, these oil-yielding shales may become worth working. They exist in great quantities.

As a proof of the durability of the Caithness pavement, a circumstance which occurred in Leith Walk, Edinburgh, about three years ago, may be mentioned. A fire broke out in a building in that quarter, and the hose for the engines was laid across the road. The ordinary traffic line being thus impeded, the cabs, carts, and waggons, some of the latter heavily laden, took to the footway, and the consequence was that for nearly 200yds. of the sandstone flags—from the north of England and other places—were broken under

the unusual weight, whereas a portion, several feet in width of the same road, laid with Caithness flags, bore all the same traffic without being injured; even the sawn edges were not chipped.

FIRE-PROOF FLOORS.

IT is rather strange that there should exist such an apparent reluctance on the part of those building to adopt the system of fire-proof floors. In many new erections which have come under my notice, and are evidently intended to be occupied as offices or warehouses, or the two combined, I have been rather astonished to find that the floors, as a rule, are all constructed after the old style, that is, of timber, so that in the event of a fire occurring on either of the floors, its progress is not impeded, but on the contrary it is assisted in its ravages by the inflammable construction of the floors. In some instances it may be found that one or more of the floors are constructed on fire-proof principles, and the remainder are of wood. I have recently had my attention called to a building where this has been the case, owing to the fire having broken out in a room the floor of which was of timber, and that under it constructed on Phillips's patent principle. I refer to Mr. Lorsont's American Cloth Manufactory, situated at North Woolwich, which was partially destroyed by fire on the evening of November 25. The building consists of a large rectangle, divided equally into four rooms on the ground and first floors, the dimensions of which are about 50ft. by 25ft. A third story was carried up occupying the central part of the building, and extended over the lower rooms, about 15ft. on each side the central wall, being the same width as the lower portion of the building. The end walls, 14in. thick, were built upon flitched timber beams with one iron column under the centre in each of the four rooms. The floor between the first and second story was constructed by Messrs. Phillips, consisting of their patent I girders 8in. deep, placed 5ft. apart from centre to centre, with ⊥ 1¼in. by 1¼in. by 3-16in. bars with slotted ends fixed on lower flange of girders 3in. apart. Upon these bars a layer of concrete 6in. thick is laid, which receives the asphalte covering; the ceiling underneath is plastered in the ordinary way, but without wood laths. The girders are each supported in the centre by light iron columns connected at their caps by iron ties securely bolted. The floor above was constructed of timber in the ordinary way, and this was the floor of the top room where the fire originated. This room was technically called the "trowelling" room, in which were stowed large quantities of materials used for trowelling or coating the cloths, consisting of various preparations of oil, petroleum, and varnish, all of an inflammable nature. On the evening of the explosion, it appears that the foreman went into the trowelling room to turn over some cloth that was drying, to do which he set his lantern upon the floor, and had no sooner done so than he perceived a flame curling round the light, which immediately filled the room, he having only just time to make his escape by the door opening on to an outside stairs. The alarm was given and the two stand pipes were soon at work, but from the nature of the burning material the fire raged and soon found its way to the floor below, where fresh fuel was added, but beyond this floor the fire did not extend. The intense heat has shrivelled up the asphalte, but failed in any degree to affect the floor, so far as the actual action of the fire had upon it. The burning of the beams which had supported the brickwork above, causing it to fall bodily upon the fireproof floor from a height of 12ft., broke through the concrete in a few places and slightly bent several of the girders, driving down the iron columns underneath, which rested upon concrete foundations. In the fourth room, where the fire was got under before the beam was so far burnt as to let down the wall, but which was afterwards taken down, the floor is uninjured.

W. B.

CHEAP ICE HOUSES—A GOOD PLAN.

AS the time for securing the harvest of ice is approaching, a few hints looking iceward may not be amiss. We remember when the ice business was unknown; only some enterprising householders or wealthy men thought of such a luxury as an ice house. Yet as ice has slid out of the category of luxuries and become a comfort, if not a necessity, it is within the power of all living in the country and having access to a pond or a stream to provide themselves and possibly their neighbours with a sufficient supply of this comfort to assist in preserving perishable articles and to temper their beverage of water. In cities and large towns men singly or in companies undertake to provide the dwellers with ice, a crop that costs nothing to plant, tend, or raise but only to gather and store, but yields handsome returns. But in the country the convenience of daily delivery of the gelid luxury is impossible and inconvenient. To our country readers, therefore, some suggestions on the construction of ice houses and the preservation of ice may not be amiss.

A family ice house, says the *Scientific American*, need not be an expensive structure. It may be built cheaply, subserve its object excellently, and add to the attractions of a homestead by being a sightly object. A building of 12ft square and 8ft. or 9ft. high is sufficient for the wants of the most exacting family. It may be a frame building, entirely above the surface of the ground, and better if supported on posts, elevated a few inches, to be certain of good drainage. Built of joists, 2in. by 3in., with an outer boarding, having inside another series of uprights, also boarded, from 6in. to 10in., removed from the outer shell, with a solid floor of plank, the space between the two walls filled with tan, sawdust, straw, or chaff, and a roof of good pitch, the ice house is complete. A drain for water should be made from the floor, and the space above the uprights, between a loose flooring and the pitch of the roof, filled with straw, hay, or some similar dry, porous material. On the roof should be a ventilator, the top defended from the rain or snow.

The ice should be packed in one solid mass, the sides not reaching the inner walls of the building, but allowing a space of from 6in. to 12in. all around. The top of the ice should be covered with straw, and the door should be like the sides of the building, or double doors should be made, one in the outer and the other in the inner wall. Plant morning glories or any climbing plant around the building and induce them to creep up the walls and over the roof as an additional defence against the fervid sun of summer.

Two workmen, if not practical carpenters, can put up such a building in one, or at most, two days, which if taste and judgment is used will prove to be a sightly addition to the attractions of a country home, and a useful adjunct to the farm, its contents being convenient and comforting in health and invaluable in sickness. Such an ice house would prove also convenient as a refrigerator on a large scale, preserving food of various kinds and the products of the dairy.

OXFORD ARCHITECTURAL AND HISTORICAL SOCIETY.

A MEETING was held on Wednesday, December 2, at which the secretary of the society, Mr. James Parker, gave an account of the Roman occupation of Dorchester, in this county. He also made some remarks upon the numerous discoveries of Roman remains in Dorchester, which city had sprung up in consequence of the neighbouring camp. The Rev. W. Jackson made some remarks upon the question of the Isc, the origin of the Isis; and after a careful paper on "Apsidal Churches," by Mr. E. G. Bruton, the meeting separated. At the meeting on Wednesday week, Professor Westwood exhibited an Anglo-Saxon MS. of the Four Gospels, in beautiful preservation, and of a date not later than the tenth century. Bound with the volume was a Lectionary, also in a fine state of preservation, and at the end, in a somewhat later handwriting (about the year 1100), a copy of the letter from Fulco, Archbishop of Rheims, in which reference is made to Grymbald, whom tradition has associated with Oxford. There was good evidence to show that the book was probably written for the rich Abbey of Hyde, near Winchester. A lecture was also delivered by E. J. Payne, Esq., upon "The Romans in Spain," in which he showed how much of the Roman customs and language had been preserved, and at the same time many of their works, especially some fine aqueducts, of which he exhibited drawings.

Many buildings at Akyab have been destroyed by the recent cyclone in the Bay of Bengal.

ARCHITECTS IN INDIA.

To the Editor of the BUILDING NEWS.

SIR,—I have just been reading your numbers of August 7 and 21, on "Engineering Architects in India." As I happen to be one, allow me a word or two on the matter. As you say, unfortunately for architecture, it has been confined to the practice of engineers (of the military) now for so long that the hope or chance of a change is but slight, or at least for some considerable time to come; and the engineers themselves, so blind and ignorant are they as a rule of architecture, in practice or requirements, will most assuredly make "no surrender." The other class, friends of and friendly to the military engineer, are disposed to make no change, and as to the public here, thinking, heedless or knowing little of such matters, that no good can be looked for in this quarter, hence no action can be taken, and so for some many years to come, unless some new broom be set to work, shall we jog along content with military art." You go on to say, "How many of the young men are there who would be glad to spend some six or seven months of their junior time in India, acquiring knowledge and practice, &c." May I, Sir, ask, Practice in what? Most certainly not in architecture; and if you mean engineering and construction, it is far easier learnt at home, where there are more varied and infinitely greater opportunities. India is no school for the student—of that I am very certain, but a field for the practical man to carry out what he has learnt at home, and these are works that are almost without exception in idea born, and in detail of construction, material, &c., matured at home.

As for the student who is to go out to India on a professional tour of "some months," with the chance of his stay "being rewarded by some commission or attended by some professional occupation," I fear, Sir, his chance is in the most trifling degree too remote to entertain. I have been in India, living for three years in one of the largest cities, have repeatedly endeavoured to obtain some commission, and have not succeeded. Had I been here on an attempt to establish myself in practice as an architect without an appointment to back me, I should simply have starved.

Allow me to state a few facts about Calcutta, where, if anywhere in India, a man might look for success or for employment. There are some five or six large public buildings in course of erection, and there is a fair number of new buildings in some new streets for dwelling-houses (European). Now, see the chance for the "student" to pick up a chance commission where, as you will see, a resident could not! The public buildings have been designed by the consulting architect to the Government of Bengal, the streets and their buildings are being carried out by a contracting firm as a speculation, which, as speculating builders invariably do, employs no architect. The result of the latter is, as you will readily conceive, architectural monstrosities in the brick-cemented, speculating builder style, as at home. This is an encouraging state of affairs for a young man to come out to to study with chance of a stray commission.

Now, Sir, see what encouragement our governing powers give. At the early part of this year, after about a three or four years' engagement, and after having obtained in this time designs for the Post Office, the Imperial Museum, the High Court, and the University Buildings from their architect (an architect who signs himself "M.R.I.B.A.," therefore one of that estimable body), they comfortably get rid of him, and hand his work or drawings finished or unfinished, but chiefly [illegible] to the tender mercies and cruel damnation of the public works engineers, who cut down [illegible] and alter to suit their own ignorance [illegible], freely encouraged by the heads of departments. Such is the encouragement a liberal and paternal government gives to architecture here.

A word about your student, who is to come to make a few studies in a few months. He will soon find his few months grow into many, or his months gone and his [illegible] empty [illegible] as empty as his purse, with the prospects of the chance commission he is to pick up. He may get to Ahmedabad and [illegible] easily, and he can leisurely and [illegible] visit the cities in the Gangetic valley, but if he would explore the riches of the interior of Assam and Sylhet, the glorious remains in Orissa and the Northern Sircars, those in Behar, Maha

vellipore, in Madras, and numberless others, to say nothing of Ceylon or Cashmere and the Punjaub, he will soon have to leave the high roads and take to the by-ways and roadless ways; 400 miles of Palkee Dâk to Orissa, and then some 200 or 300 more when there to get from place to place, will soon run into the few months' trip. Two months of travel to get two weeks' study and sketching would need more than a student's purse to pay for: he would have to camp it (no great hardship that), to take his servants with him (this is indispensable), his cooking utensils—in fact, all he would want he would have to take with him, excepting food; and in the way of food he must content himself in great measure with leguminous food, and trust to his gun to find him something savoury. He would need be a far different man from the general sketching man, delighting sometimes in the name of student, sometimes "rentiér," that I have met in my wanderings in Europe, comfortably turning out of his hotel in the morning, sometimes sketching until breakfast time, never by any chance becoming so engrossed in his work as to let that pass by unheeded. After breakfast again leisurely out sketching, with plenty of etching and pretty picture making until dinner bell sounds, when in he turns again, with half-finished sketch on board, to be completed on the morrow. This is doing it comfortably and gentlemanly. Nothing such as this would your student get here. Eight months out of the twelve sketching out of doors would be an utter impossibility after nine a.m. or before five p.m. I have enthusiastically tried it myself up to ten a.m., in the month of October, and paid the penalty with a slight fever. I am not raising difficulties where none exist, and may be allowed freely to give an opinion on such a matter, as I have had a fair share of architectural study in Europe, occasionally a turn of the feather-bed hotel style, and would gladly and readily launch out into an Indian study and sketching tour; but such a thing requires more time and money than men at home would be inclined to think.

"Monuments of our sway that are to commemorate our endurements and our merits," you say! Then, if monuments, nearly all we have erected in the so-called "City of Palaces" are monuments of pretentious ignorance—so many separate instances of military engineer architecture. Baker-street and all the numerous similarly built streets are almost preferable to the ignorance that flaunts itself in India. Sir J. Rennie did not put architecture in the civil engineer's curriculum in order that he might practice it, any more than that he added mineralogy and geology in order that a man might live with Hugh Miller.

In conclusion, with reference to your remark as to the exploration of India, the peculiarities of country and climate are such that it can never be explored by individual and private enterprise, unless some rich archæologist do it. Nearly all that is now known of India and its architectural riches has been made known and reported on by men on some service, political or other, and therefore by the State. Time and cost are the two formidable obstacles against any speedy researches of Indian architecture. The Hooghly Bridge, of which you make mention, will, I fear, be the "blot"—it has come down already to a floating bridge, and things bid fair to take it from the hands of the original schemers of it, to one of whom, the late consulting architect to Government, we might have looked for something good—for something at least out of the hideous, and have put it under the fostering wing of the Government and their Public Works Department. The illustration in your paper of a week or two back of engineer's architecture—*at home too*—will lead you to imagine what it must be out here.—I am, &c.,

Calcutta, October 8, 1868. AN ARCHITECT.

NEW HOSPITAL, NEWCASTLE-UPON-TYNE.

THE ceremony of laying the foundation stone of the new hospital in connection with the Newcastle-upon-Tyne Poor Law Union Workhouse was performed on December 9, by Henry Milvain, Esq., J.P., vice-chairman of the board of guardians. The hospital is intended for the accommodation of 200 patients, being sick and infirm inmates of the workhouse; and the estimated cost of its erection is £14,000. The building will face the turnpike road, and is situated to the west of the present workhouse, forming three sides of a quadrangle, the latter being open towards the south. The east and west wings will be two stories in height, each containing two sick wards 94ft. long, 24ft. wide, and 14ft. high. The range on the north side of the quadrangle will also be two stories in height, and contain two wards on either side of the centre building, 88ft. long, 24ft wide, and 14ft. high. The centre building will be three stories in height, and is appropriated to nurses' rooms, sculleries, surgery, committee room, &c. Attached to each ward will be a set of water-closets and bathroom, separated from the main building, and constructed so as entirely to preclude the admission of any effluvia into the wards. At the south ends of the east and west wings, and at the junctions between these wings and the north range, day rooms will be provided for the use of those patients who are approaching the convalescent stage. To the rear of the centre building will be erected the cooking kitchen, which will be fitted up in the most approved style to meet the requirements of a hospital. The arrangements for ventilation, drainage, and water supply are most complete and efficient. The eastern side of the building is appropriated to females, and the western side to male patients. The walls will be entirely of stone, and the style may be called domestic Gothic, adapted to modern requirements. The work has now been in progress for some three months, and has been executed so far in a satisfactory manner by the eminent contractor for the mason work, Mr. Robert Robson, of Wideopen, under the superintendence of the architect, Mr. Septimus Oswald, and his efficient clerk of the works, Mr. Geo. Nixon.

CONVENT OF ST. MARGARET, EAST GRINSTEAD.

WE give this week a double-page illustration, with plan, of these buildings, which are now in course of erection for a sisterhood in connection with the Church of England. One side of the quadrangle is deferred for want of funds. The works are being erected by Mr. Fabian, contractor, of Brighton, and will be completed the early part of next summer, at a cost of about £10,000. Mr. George Edmund Street is the architect.

ARCHITECTURAL ASSOCIATION.

ON Friday evening last, at the ordinary general meeting, Mr. W. White, F.S.A., F.R.I.B.A., occupied the chair, and the following gentlemen were elected members:—Messrs. Charles I'Anson, Ernest Geldart, S. P. Close, A. W. Dresser, Charles B. Oliver, Daniel Bell, G. Saunders, F. P. Johnson, Richard C. Page, James O. Parsons, S. R. Neate, George V. M'Clellan, and Charles Coates. The members then unanimously sanctioned the appointment of the delegates nominated by the committee of the Association to serve on the Architectural Education Committee, those gentlemen being Messrs. White, Spiers, Tarver, and Ridge. Mr. Phené Spiers then directed the attention of the members to the drawings and designs for a proposed natural history museum which have recently carried off the £100 Travelling Studentship offered by the Royal Academy, their author being Mr Herbert Marshall, a member of the Association. The chairman next called upon Mr. E. I'Anson, F.R.I.B.A., to read a paper on "Russian Architecture" Mr. I'Anson, in commencing, said that, although he had already read a paper on Russian architecture at the Institute, the subject was by no means a hackneyed one, and he thought that a paper of the kind would prove more acceptable than a dissertation on those styles of architecture which had mainly engrossed his attention during his professional career, viz., Italian and French Renaissance and the modern works of Paris. As a proof of the comparative novelty of his subject he referred to the scarcity of photographs of Russian buildings, although there were many Russian works which were well worth study. After graphically describing the architectural aspects of the Kremlin of Moscow and the buildings contained within it (the description being substantially the same as that by the same author, given on page 59 of the present volume) the author dwelt on the prominence given in Russian churches to the iconastasis or altar screen, and to the lavish manner in which that and all portions of the church are decorated with the most costly materials. As a novelty he referred to the Cathedral of St. Basil, only 150ft. square, yet containing on the upper story nine distinct chapels, and twelve on the ground story. Each of these had its own iconastasis, gorgeously decorated with sacred pictures in frames of fabulous value. As to the architecture of these Russian churches, Mr. I'Anson had not the least doubt that it was taken from Constantinople, whence the Russian faith came. From the great sums of money expended on the interiors, the exteriors of Russian churches are necessarily composed of the poorest materials, and from the severity of the climate constant white-washing, painting, and plastering are necessitated. Though this is the case, the Russian churches have been preserved almost in their integrity since their erection in the fifteenth century, but only through the deep religious feeling of the people. The emperor's palace within the Kremlin contains a valuable collection of early Byzantine works, such as ivory thrones, &c., and specimens of furniture, &c., in the richest style of Oriental art. The striking feature of St. Petersburg is the prodigal liberality with which it is laid out, with its streets, squares, and granite-quayed walls. The great street, which is called the Nevski Prospect, is a couple of miles in length and twice the breadth of Portland-place. St. Isaac's Church has a central dome, with four small cupolas around it. That dome is absolutely covered with gold plates. Common to most Russian towns are buildings corresponding to the bazaars of Constantinople. In the Kazan Church, St. Petersburg, the granite columns to the four porticoes are monoliths, 60ft. high, with capitals all in one. Lapis lazuli is abundantly used in this church At St. Petersburg there are two very magnificent collections of pictures, and a remarkably fine collection of Greek work from Kertch. Malachite, porphyry, gold and other materials are lavishly used in church decoration. At the conclusion of the paper, which was illustrated by numerous drawings, plans, and photographs,

A short discussion ensued, in which the president. Mr. Phené Spiers, Mr. Blashill, Mr. Ridett, Mr. Quilter, and another gentleman took part. In reply to some of the points raised, Mr. I'Anson said that one of the peculiarities of Russian architecture was the extreme poverty and gorgeous magnificence which stood side by side. Marble buildings and humble wooden cottages stood in juxtaposition. At the Paris Exhibition there was a caricature of a Russian wooden building designed by a French architect. He (Mr. I'Anson) had not brought Russian architecture before the Association as a high type of art, but merely to show how one great section of Europeans had tried to adapt construction and design to their needs. In responding to the vote of thanks accorded him, he said he should have great pleasure in lending any of his sketches for reproduction in the Association's "Sketch Book."

SCHOOLS OF ART.

ON Tuesday evening Lord Houghton presided at the annual distribution of prizes at St. Martin's School of Art A statement made by the Rev. R. G. Maul, the honorary secretary, showed that at the examination held in March by the Science and Art Department at South Kensington, 85 students presented themselves and worked out 79 papers successfully in geometry, perspective, free-hand and model drawing, for which certificates and 27 prizes were granted, consisting of books, water colours, &c Seven free studentships had been awarded for the most satisfactory works sent up during the year. One of the ten gold medals offered by the Science and Art Department, and competed for by all the art schools in Great Britain and Ireland, had been given to E. F. Clarke, and the second prize (£5), offered by the Plasterers' Company for the best design in plaster, had been awarded to Geo. Jepp. Mr. O'Neill's prizes were awarded to Annie Walker, J. Lucas, and L. G. Luker; while A. Johnson, S. Hodson, and Mary Cornelison were declared the winners of the prizes of the Sketching Club. After distributing the prizes the noble lord delivered a brief address. He said it was impossible to look at the works exhibited in the room without acknowledging their general excellence, and seeing that in their execution the great models of study had been followed. The schooling on the whole was a good one, because it did not teach mere showy and fantastic effects, but it required and favoured accurate, simple, and masterly drawing. Mr. Digby Wyatt and Mr. O'Neill addressed the meeting. Cordial votes of thanks to the noble lord, Mr. Casey, the head master, and the Rev. Mr. Maul, terminated the proceedings.

The annual distribution of prizes to the students at the Maidstone School of Art took place on Friday evening last. From the report it appeared that the school was opened on January 29, 1867, under the care of Mr. J. B. Williamson. Three classes had been formed from the commencement, and 127 students had passed through the school, 62 being now under instruction—builders, clerks, bricklayers, ticket writers, upholsterers, carpenters, engineers, masons, and others. The report closed with a suggestion, which we trust may be acted upon, that prizes should be offered by the townspeople.

RECOLLECTIONS OF ENGLISH ENGINEERS.*

THE merit of first bringing into public notice, through the medium of the press, the incidents and routine of an engineer's life is undoubtedly due to Mr. Smiles. However interesting, either in reality or in fiction, the events occurring in the lives and practice of the members of other professions might be, it was not considered that those pertaining to the civil and mechanical engineer were worth recording. It is true that there are but very few sensational incidents which arise to break the somewhat monotonous course of the engineer, especially at home, and, besides, "his works live after him." It would be difficult to endow his practice with the halo of romance that attends that of the barrister and the medical man. No thrilling trials, no curious and absorbing relations of fearful crimes, in which, after long eluding an active search, the criminal is finally brought to justice by some splendid *coup de main* or subtle ingenuity of a cunning detective, distinguish the "lives of the engineers." They furnish no materials for the production of a volume similar to "The Memoirs of a Physician," nor are they rich in "beautiful maniacs," or in the exciting details of cataleptic idiosyncracy. That, nevertheless, they contain sufficient materials to furnish an interesting and instructive volume is evident, not merely from the one we have alluded to but from that now under notice. Our author has followed the path opened up by Mr. Smiles, and introduces us to some new phases of a profession that has done more than monarchs and statesmen to civilise mankind, and bring into union and combination the people of every land under the sun.

With the exception of Brunel and Stephenson, and a few others, the earlier engineers do not appear to have been particularly amiable or gentlemanly in their manner and bearing towards their pupils, assistants, and those with whom they were brought into contact. Many of them were characterised by an insolence and obstinacy which were only equalled by their total want of professional skill and ability. In fact, it would be impossible to expect anything else of some of them, if we bear in mind the circumstances that gave rise to their position. There is no parallel case in history where the services of a particular class of men were required so suddenly and so extensively, and, moreover, where the supply was so inadequate, in every sense, to the demand. Men were thrust at one jump into situations of trust and responsibility for which they were utterly unfit, and, what is worse, numbers of them never took any pains to qualify themselves for the post that they voluntarily accepted. In addition, some, and these were invariably the most ignorant, not only refused to accept hints from members of their staff and others who were better acquainted with the details of the profession than themselves, but treated with contempt and scorn any suggestions that were thrown out for their good and advantage. One can hardly credit, what we have the authority of the writer for, that a resident engineer did not know how to measure properly a "batter level," an implement used for ascertaining the slopes of the cuttings and embankments. For the violent and vituperative language which some of the "chiefs" were in the constant habit of indulging in, there is, perhaps, some palliation. In the first place, the practice of swearing, like that of drinking, was much more prevalent at that time than at present, and, secondly, there is no question but that the pupils and assistants were frequently a very rough lot to deal with. There is no doubt that some of them were not amenable to anything under "strong language," and it must also be borne in mind that many of the "chiefs" themselves were nothing better than foremen. There were no young men of family and education crowding into the ranks of the profession as at present, nor was it recognised as an educated and learned profession. It is only very recently, indeed, that that title has been accorded to it.

The position of the engineer was, in the early days of steam locomotion, infinitely superior in point of authority and personal importance to what it is now. His dictate, his certificate, and his recommendation and advice were paramount with the directors and company. It is rather singular that this should have existed when the men who filled the situations were by no means so well calculated to perform those offices of trust as those in a similar position at present, when the conditions of affairs are reversed. An engineer-in-chief is now so hedged in by his directors, so watched by the shareholders of the company, and his power and even his discretion so circumscribed, that he may be said to be a mere phantom of his former self. It is a common remark that the enormous preliminary or parliamentary expenses which attended the obtaining of the Acts for our early railways, is the reason of their cost contrasting so unfavourably with those of other countries. There is a great deal of truth in this remark, but it must also be recollected that large sums, totally unnecessary, were spent upon the actual construction of the works. In numerous instances, the absolute want of all theoretical and practical knowledge of constructive details was only compensated for by the lavish and indiscriminate use of materials. Engineers were, in fact, only feeling their way, and there is no wonder that, in order to be on the safe side, they trusted to weight and the mass to supply the defects of the actual construction. The author mentions that Brunel's work was characterised especially by a skilful attention to scientific rules; and his masonry was distinguished from that of many of his *confrères* by its comparatively small dimensions. The relation of the failure of the Dee Bridge, and the trial that ensued, is extremely interesting. It is scarcely necessary to remark now that the principle of design adopted for the bridge in question has been long abandoned, and was not sound in theory. At the same time no blame could be fairly attached to the engineer of the line, who, as it was, narrowly escaped a charge of manslaughter. The accident was the cause of the scientific inquiry that was shortly afterwards carried out by a royal commission, respecting the application of iron to railway structures.

There is one point in which railway engineering of the early days has no compeer. It is the question of payment. The salaries of the engineers, the balance to the contractor, was paid in specie, not in shares, bonds, debentures, or any other security floated in the market. Unquestionably, the status of the profession, if less educated, less refined, and less acknowledged, was more honourable, more *bonâ fide*. Not only are the contents of the volume under notice replete with anecdotes of the field and the office which may amuse and interest all readers, but several very good hints and suggestions are scattered here and there with respect to failures that have occurred in works of construction. It would not be difficult for us to identify some of the "chiefs," who are not mentioned by name, but were we to do so, we should defeat the object of the writer, and also in some degree disappoint his future readers, who will probably like to find out themselves "whom the cap fits."

* "Personal Recollections of English Engineers and of the Introduction of the Railway System into the United Kingdom." By a CIVIL ENGINEER, Author of the "Trinity of Italy." London: Hodder and Stoughton, 27, Paternoster-row. 1868.

The collection of paintings—principally of the Dutch school—which formerly adorned the mansion of the late Sir Henry T. Hope, in Piccadilly, has been lent by his widow to the South Kensington Museum, where a large room has been specially fitted up for their reception.

Building Intelligence.

CHURCHES AND CHAPELS.

The parish church of M[illegible], N.B., has recently had after restoration. [illegible] the [illegible] was erected [illegible] the late Mr. John Henderson. [illegible] consisted [illegible] of about [illegible] ft. to the length of the building and the formation of a transept at the east end. The church now accommodates [illegible] persons. The cost of the alterations was about £[illegible]. Messrs. Peddie and Kinnear were the architects, and Mr. Arthur [illegible], the contractor.

The ancient church of Whissendine, Rutland, has for some time past been under restoration. Mr. A. Goddard is the architect, the contractor being Mr. J. East of Melton Mowbray. A large public room and institute is about to be erected in the village from designs by the same architect, and at the expense of the vicar.

On Monday week a new church at Appleton-Roebuck, about nine miles from York, was consecrated. The plan consists of nave and chancel, with bell turret, porch, and vestry. The materials used were Bradford sets for the walls, with Ancaster stone dressings. The cost of the building is about £2,[illegible]. The design is [illegible], and is by Messrs. J. B. and W. Atkinson, architects, of York.

The new Episcopal Church at Dumfries was consecrated last week. It has been erected from the designs of Messrs. Slater and Carpenter, of London, the Duke of Buccleuch being one of the chief contributors to the building fund. It has a wide and lofty nave, side aisles, chancel with vestry, and a tower and spire 12[illegible]ft. high at the north-west angle. The walls are built and faced inside and outside with coursed Dumfries stone with bands of Prudham stone. The columns of the arcades and the inner order of the arch mouldings are also of Prudham stone. The covering of the roof is of Silbethiocult slates. The style is severe Early Pointed, necessarily on account of the hardness of the stone and its consequent expense in working. The clerestory has three lancets in each bay, of lofty proportions, thus a great effect of height is gained. The nave has in the west wall a triplet of three lancets, with a rose window over, and a moulded doorway with carved tympanum beneath. The chancel has three broad lancets, with an arcaded reredos below. The roofs are of deal, that of the nave has massive moulded tie beams and king posts with moulded and carved braces and wind braces. The seats are open and very simple in design. The paving is of Caithness stone. The lower stage of the tower forms a north porch, and has deeply recessed and moulded doorways with carved tympana. The tower batters slightly. The windows of the belfry are simple pointed recessed lights, over which is a double corbelled cornice, from which springs the spire. About half way up the spire are cusped openings, over which are moulded and arched canopies, forming in effect a crown round the spire. Many of the windows of the church and chancel are filled with stained glass by Clayton and Bell. The whole of the works have been carried out by Messrs. Crackston, of Dumfries, Mr. Palfrey being the clerk of works.

BUILDINGS.

The Eastbourne New Gas Company's works were formally opened on Saturday, December 5. The works, which were commenced in May last, are now completed, and in full operation. The coals are brought on to the works by a railway siding, and [illegible] the railway trucks into smaller trucks, which are then raised by a hydraulic lift and [illegible] on an elevated tramway into every part of the [illegible] stores, which are situated on each side of the retort house. The retort house is built for [illegible] clay retorts, each [illegible]ft. long. The works are also provided with an annular condenser, two engines, which work the two exhausters as well as the water, tar, and liquor pumps, and the hydraulic lift; a scrubber, [illegible]ft. diameter by 2[illegible]ft. high; two purifiers, [illegible]ft. square by 5ft. deep; the two purifiers from the old works will be used in addition to these; a brick gas-holder tank containing a holder [illegible]ft. diameter by 2[illegible]ft. deep; a station meter, a governor, tar and water tanks, &c., and a manager's house and offices. The works were constructed from the designs and under the superintendence of Mr. Alfred Williams, of 64, Bankside, London, the company's engineer.

On Saturday afternoon the president of the society laid the foundation stone of a new Mechanics' Institute and School of Art at Keighley. The style is Gothic, and the building comprises a lecture hall, capable of seating 1,000 persons. The cost of the building, including land charges, will be about £12,000. Messrs. Lockwood and Mawson, of Bradford, are the architects, and the work is being executed by local contractors.

On Tuesday week new parochial schools were opened at Uppingham by the Bishop of Peterborough. The buildings are constructed of local limestone with Bath stone dressings. The cost is about £2,200. Messrs. E. F. Law and Sons, of Northampton, are the architects, and Mr. Bassett, of Little Bowden, the builder.

Much has been said and written of late as to the advantage of using Portland cement concrete as a substitute for brick and stone in the erection of various kinds of buildings. The Duke of Northumberland, according to the *Newcastle Daily Journal*, has been the first to practically test this mode of construction in the north by ordering the erection of a cottage of three rooms, scullery, and other conveniences, at Church Bank, Alnmouth. The site is on a sand bank close to the seashore, and contiguous to an old cemetery once connected with the main land, but now, at certain times of the tide, an island. The material used in the construction of the cottage is Portland cement and gravel from the seashore. The foundation is on the sand 6in. thick, and 18in. wide. On this there is a base course, and above the walls are 9in. in thickness. Part of the erection is two stories in height. The roofs are all flat, and are constructed entirely of concrete and old wire rope. The ceilings are divided into panels by ribs at right angles, and require no plastering. A wall on the upper floor is supported on a concrete beam 13ft. span; a large cistern is formed under the roof of the pantry for rain water; the sides of the cistern being the walls of the bedroom will severely test the impermeability of the material. No wood is used except for doors, and no iron except about five shillings worth of old wire rope. We understand the cost will be about 20 per cent. in favour of concrete over brick and stone, timber and slates, with the additional advantage of being fire, weather, and vermin proof. The building has been erected by Messrs. W. B. Wilkman and Co., of Newcastle-on-Tyne.

The almost unparalleled increase of Dewsbury and Batley during the last ten years has compelled the Gas Company to enlarge their works by establishing branch works near Batley; and they have further increased them this year by the addition of a telescope gasholder, 120ft. in diameter and 64ft. high. The tank is constructed of ashlar and puddled; and the work has been executed by Mr. Brier, of Dewsbury. The whole of the works have been erected from designs prepared by and under the superintendence of Michael Sheard, of Batley, C.E., at a cost of near £13,000.

BUILDING AND LAND SOCIETIES.

THE Conservative Land Society had its sixteenth annual meeting on Tuesday afternoon. The report of the board stated the receipts for the year ending September 30 to be £188,342 19s. 6d., and the grand totals to be £1,288,846 7s. 3d. since the formation of the society; the total withdrawals being £328,984 19s. 6d., and the £50 shares issued to £1,527,700. The sale of land was £583,650 15s. 1d.; the reserve fund was £15,089,132. The increase in the various sources of income for the year reached £81,824 9s. 3d. The dividend for the year was declared to be 6 per cent. The rate of interest on shares remained at 5 per cent., and on deposits at 4 per cent per annum. The report stated that the land business was now carried on by the United Land Company (Limited), and the advances on building loans on security, &c, were made by the Conservative Land Society, the combined principle of action having worked successfully.

The thirteenth annual meeting of the York Building Society was held on the 7th inst. in that city, the Sheriff presiding. The report stated that the number of shares issued has been 454, nearly double that of any previous year; the withdrawals have been 182, but in these are included 59½ that had arrived at maturity, upon which £100 purchase has been paid, with a bonus of 10s. 6d. per share. Advances to members have been made amounting to £15,645, a sum considerably in advance of any previous year. Interest at the rate of 4 per cent. per annum is allowed on prepayment of subscriptions, they being repayable at call, whilst interest at 3½ per cent. is allowed on the paid up shares, which amount at the present time to £12,025. The receipts to the credit of the Contingent Fund amount to £160 11s. 5d., exceeding the expenses of management by £25 11s. 10d., one third of which has to be carried to the Reserve Contingent Fund, which will then stand at £153 8s. 11d. The directors propose to pay a bonus of one guinea on all shares of £100 becoming payable during the ensuing year. The abstract of the accounts of the society were then submitted to the meeting, and both that and the annual report duly adopted by the meeting.

NOTICE.

FRIDAY NEXT being CHRISTMAS DAY the "BUILDING NEWS" will be PUBLISHED on THURSDAY, December 24, at the usual time. Advertisers and others are, therefore, respectfully requested to forward all Communications by FIVE P.M. on the preceding WEDNESDAY.

TO CORRESPONDENTS.

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

RECEIVED.—T. J. F. W.—G. T.—I. F. M., with drawing of dry-ash scheme.—I. W.—S. W. and Co.—G. P.—S. and H.—W. F. Y.—W. H. L.—C. B. A.—T. M.—W. W.—I. N.—J. M. and Co.—J. P.—E. W. G.—G. R. and Co.—R. S. N. and Co.—W. H. L.—F. W. C.—C. B.—I. N.

BOOKSELLER'S question is purely a legal one. It is better to consult a respectable lawyer.

ART.—On a preceding occasion we inserted your letter, though not authenticated. We cannot do so the second time, and particularly as you indulge in personalities in reference to Mr. H. H. Statham.

"Geo Turner's," "Young Architect's," "A Beginner's," "William Carlisle's," and "J. L's" questions, with others of the sort, will be inserted the week after next under a separate heading.

Several questions and answers for "Intercommunication" are postponed till next week.

Correspondence.

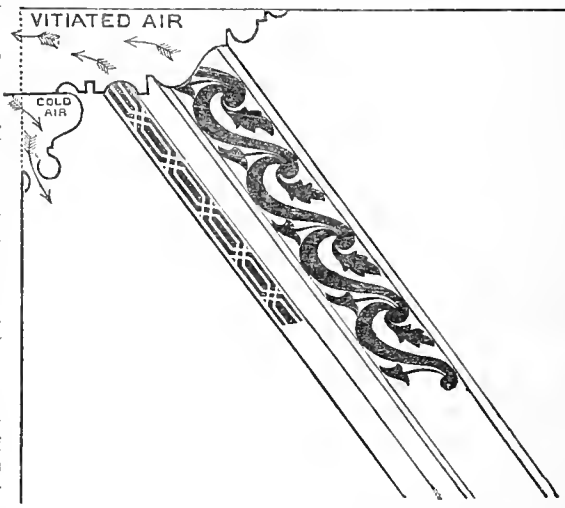
POTTS'S PATENT VENTILATING CORNICE.

To the Editor of the BUILDING NEWS.

SIR,—The comments upon this invention in your last number by Mr. J. J. Cole appear to have been made from a misconception of my ventilating system. I called at his office, when he most courteously discussed the subject with me, and explained the details of his plan, which he had referred to in his letter. We found that in ventilating by means of the cornice we differed essentially in our modes of effecting that desirable purpose. Mr. Cole considered that on my publicly stating this difference of our modes I should supply a diagram to show my main feature of construction. It is here shown, the arrows marking the currents of vitiated and cold air respectively. It will be seen that on my plan the former air is discharged near to the ceiling, while the cold air is advantageously taken from the highest available point, the plan being of the most simple character and in strict accord with natural laws. Mr. Cole also stated I might well intimate to architects that their designs, however elaborate, might be effectively carried out on my plan. I shall soon publish testimonials from eminent scientific and professional authorities, both as to its satisfactory purification of the air of rooms and beauty in effect.—I am, &c,

WILLIAM POTTS.

Wood's Hotel, Furnival's Inn, December 10.



HER MAJESTY'S THEATRE.

SIR,—On turning over the back numbers of the BUILDING NEWS after a somewhat lengthened stay in Italy, I have been pleased to see your account of the forward state of the new opera house. It is especially a matter of rejoicing that the acoustic qualities of the theatre have so far been studied that the decorations are to be free from raised ornament. It has long appeared to me a matter of regret that none of the existing journals should consider the decoration (internal) of public buildings to be of sufficient importance to merit special and systematic criticism. Were these works criticised, say in a paper like your own, with even the care and judgment that are bestowed on any other artistic productions in which the general community is interested, we should probably be tortured by less of those crude, vulgar attempts at embellishment which meet the eye on every side. And notably theatres might be a little less offensive. On Friday night last I visited the newest, and, as the advertisements term it, the "most elegant and commodious theatre in London," and was disappointed to find nothing but what I can only term the old gin-palace style of decoration. Tastes differ, however, and your contemporary, in what appears as a compromise between an official description and a leader, speaks of the effect as "bright and *smiling*." I do not indeed say that the interior of the Globe Theatre is coarser than that of the average of our playhouses, but the fact is that, if we except the Princess's and the Haymarket (which are very far from good) and the Queen's, which is unfortunately marred by the archaic treatment of the figure subject (in itself a noble work of art, but utterly inapplicable to its present use), there is not a single theatre possessing the slightest pretension to artistic merit in the adornment of its "salle." Perhaps this is hardly to be wondered at considering the singular ignorance and indifference to art that exists not only in the British playgoer, but also in the gentleman who "does" the theatrical criticisms for the newspapers.

I am only enunciating a truism when I say that the love and appreciation of harmony in colour and harmony in music are usually co-existent. The old Her Majesty's Theatre was always delightful to enter. In spite of much that was false in the drawing of the details, the general scheme of the whole, the richness and yet subdued tone of the colouring (especially after the restoration on Mr. Mapleson's accession), and the bright play of fancy that gave life to it all rendered the long *entr'actes*—inseparable from grand operas—a striking contrast to those spent in that vast wilderness of depressing ugliness and gloom, the Covent Garden Opera House. And in a country where the *foyer* is not a recognised institution, it is no small advantage to be able to amuse the eye whilst you please the ear.

Let me ask you to visit St. James's Hall if you have not yet done so since it recently emerged from its long-standing grubby state to a condition of the butterfly-like brilliancy, and you will, I think, share the feelings with which I listened the other night to Beethoven's matchless septet. I suppose few persons with a soul for anything above yellow ochre and French blue have ever admired the dire crudities of Mr. Owen Jones's colouring (except under peculiar circumstances, when I should be one of the first to do him honour); but, objectionable as was the original decoration of the hall, it might have emanated from Titian or Veronese when compared with its restored condition. I am happy to say that I have no idea who has been permitted during the vacation to dazzle and half-blind the eyes of visitors, but I apprehend that Mr. Jones himself (with all the strength of optic which he must possess) would stand aghast at the terrible masses of pure vermilion above the windows, and at the huge sticks of sealing wax that have been made to take the

place of the gilt rain-water pipes that formerly did duty for columns. [illegible] the nature of the evidence that they [illegible] disagreement is a positive [illegible] order that at any rate it may [illegible] those who may have the arrangement of the [illegible] of Her Majesty's Theatre.

Trusting that I have not trespassed [illegible] yours sincerely, [illegible].

P.S.—Since the purchase of the old box formerly [illegible] Her Majesty's were exhibited at a recent [illegible] Crystal Palace exhibition. Might not the [illegible] boxing of these be studied with advantage in the new theatre?

Intercommunication.

NOTICE.—As several numbers have passed [illegible] the figures and formulæ [illegible] correspondents are frequently requested to write as legibly as possible, and to write on only one side of the paper. Queries and answers [illegible] the names put to them for the purpose of publication and indexing. Answers to queries will [illegible] corresponding number and name of the query to which they refer.

QUERIES.

[1179.]—PAVING SIDE-WALKS.—[illegible] will you readers kindly inform me of the best way of laying a circular saw for ripping and [illegible] by hand? Should I gain more power by using the saw I spindle of flywheel [illegible] a leathern cylinder worked [illegible] hang from flywheel? What size would be best for the purpose?—A. B.

[1180.]—SISTERN LININGS.—[illegible] the middle of the width of the two thirds, and vertical [illegible] for lining water cisterns, leaving [illegible] —Scotia.

[1181.]—PAVING STREETS.—[illegible] some stone that in order to afford a more perfect [illegible] for the horse, that ridges are sometimes placed between the paving stones. Will some one inform me how this is done, and if done, whether it is [illegible]? —E. [illegible].

[1182.]—PRIZE COTTAGE DESIGNS IF ANY EXIST.—Can any one oblige by sending me their address, for communication, by whom any of these designs are published, and the cost per sheet or set?—S. [illegible].

[1183.]—EMIGRATION—QUEENSLAND [illegible] NEW ZEALAND.—I am a builder and [illegible] with [illegible] trade and with a small capital intend to emigrate [illegible] land and New Zealand are the places I have in view, [illegible] you or any of your readers give me any information as to the circumstances of those places and my chance of success?—N. J. Plumbow.

[1184.]—LAW OF BUILDING SITES.—Can you tell me if there was not an Act passed during the last session for facilitating the exchange of sites for buildings for charitable purposes? If so, can you give me the title of date, or give a short abstract of the provisions?—[illegible] Lawyer.

[Yes, it was passed [illegible] 1868—31 and 32 Victoria, cap. 44. It repeals so much of previous acts as render [illegible] unalienable provided with [illegible] be made for a fair consideration, [illegible] and that [illegible] each piece of land shall not exceed [illegible] acres. It may be applied for in Chancery, but the [illegible] to be heard [illegible] in order to [illegible]—Ed. B.N.]

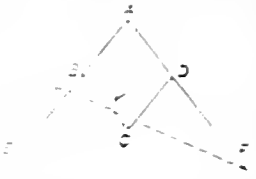
[1185.]—FIXING A BALCONY.—I have a [illegible] with long [illegible] with wire forming the [illegible] about 18in. deep and 3in. thick, and [illegible] with. I want to fix a balcony [illegible] the wire with [illegible] resting on the front [illegible] of the window sashes [illegible] intended to be formed of [illegible] ornamental [illegible]. I wish to know the best method of forming the [illegible] and how to calculate the [illegible] and the [illegible] and the best mode of securing [illegible] of the [illegible]. The balcony would at times be filled with people.—E. [illegible].

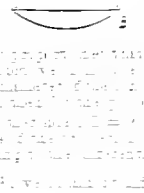
[1186.]—THE BOARD OF WORKS AND NUISANCES.—I am a householder in a large borough, and my next door neighbour complains of foul smells in the passage which adjoins my water-closet. All my drains, &c., have been examined and are in perfect order, but the inspector now says I must have the ground beneath removed and the drains examined. As no complaint has been made for the last twenty years, and the [illegible] has been [illegible] and the drains are all right, can I make them do it, or else pay the expense of examination?—J. L.

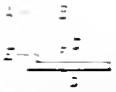
[1187.]—MARTIN'S CEMENT.—Will some of your correspondents inform me of what materials and the process of manufacture of Martin's cement, and [illegible] practical instructions to plasterers how to use the same, in the finishing of the walls in rooms, staircases, and [illegible] of buildings?—D. L. T.

REPLIES.

[1132.]—ROOF CONSTRUCTION.—If "Public's" assertion be correct, "what tensile strain is a metal rod will cover when the walls have not sufficient stability to resist the outward thrust of the rafters," and that [illegible] would be an example of bad construction. It would seem to follow that to use a tie-rod under the conditions of insufficient stability in the walls would be bad construction. But is he sure that he is right [illegible] such a theorem? He will remember that [illegible] the beam in a common [illegible] not like a [illegible] notwithstanding the stability of the walls [illegible]







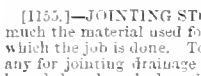
when washed over is to mix it fresh every day it is wanted. This is a tedious operation, but it repays the trouble well when the drawing is finished.—JUNIOR DRAUGHTSMAN.

[1153.]—DEALS AND BATTENS.—"The Calculator," 500 pages, 12mo., 7s. 6d., by Charles Gane, of Wisbeach, will give "A-pirant" the information he seeks.—L. D.

[1154.]—MAKING BRICKS WATERTIGHT.—I can assure your correspondent that the coating of boiled oil will not be of the slightest use in making his side wall waterproof. He may either slate it with slates laid in Portland cement, or he may pay it over with that material, which will effect a cure. The reason stucco is not generally watertight is that it is often of so very inferior a quality, being little better than dirt.—MOSLIN.

[1155.]—JOINTING STONEWARE PIPES.—It is not so much the material used for jointing pipes as the manner in which the job is done. Tough clay is as good a material as any for jointing drainage pipes, but it must be thoroughly kneaded and worked in by a man who understands the work. It will not do to merely daub it in, as I have seen it done, and suppose the job finished. The pipes will all leak after a short time. White lead, or putty, is sometimes used.—H. H. H.

[1158.]—COMPOSITION LETTERS ON STONE.—If a dovetail is cut in the stone, similar to the annexed cut, lead can be run into it and afterwards smoothed off, and will last as long as the stone itself.



A chemist will, perhaps, tell "Ignoramus" how to tint this lead various colours.—A BEAVER.

[1163.]—AREAS OF CIRCLES.—"C. E. O." will find the two following general methods useful for obtaining circles of proportionate areas to given circles. It is required to obtain a circle one-half the area of the large circle A B (fig. 1). Divide the radius A C into two equal parts at D, and with D as centre and radius D A describe the semicircle. Erect the perpendicular D E, and the chord C E will be the radius of the required circle. By a similar mode of working, any proportionate area may be obtained. Thus, suppose we wished to obtain a circle having (say) three-fifths the area of the large circle A B. Divide A C into five equal parts, and from the third division from the centre erect the perpendicular x y. The chord C y will then give the radius of the dotted circle, which will have three-fifths the area of the large circle. Second method.—It is required to find a circle of half the area of the large circle A B H. Produce the diameter A B to D, making B D equal half A B. Find a mean proportional to the two lines A B, B D, thus—on A D describe the semi circle, and from B erect the perpendicular B E. With half B E as a radius, describe the circle F G, which will have half the area of A H B. If we required any other proportionate area (say one-third), make B x = ⅓ A B; describe the dotted semi-circle, and the mean proportional B y will be the diameter of the dotted circle, which will have one-third the area of A H B. By this method of working, any parallelogram, triangle, or polygon, &c., may be made of proportional area to any given similar figure. Thus—suppose A B to represent the side of a polygon, &c., and we wished to construct a similar figure having one third the area, then B y would be the side of the required polygon, &c.—J. S. R., Nottingham.

FIG. 1.

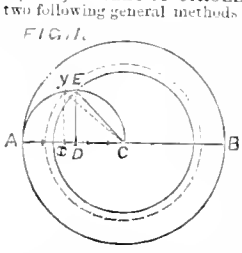


FIG. 2.

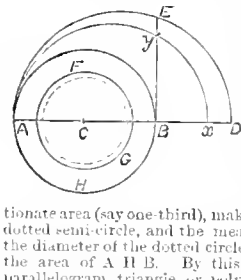
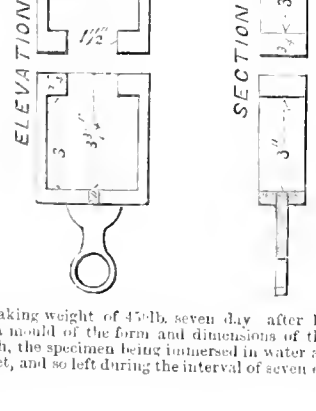


[1166.]—TEST FOR PORTLAND CEMENT.—In answer to "Cement Advocate," Portland cement should not weigh less than 100lb. per struck bushel (filled into a bushel measure as lightly as possible), and capable of maintaining a breaking weight of 450lb. seven day after being made into a mould of the form and dimensions of the annexed sketch, the specimen being immersed in water as soon as it has set, and so left during the interval of seven days.—F. C.



[1170.]—WEIGHT OF ICE.—In reply to "Jack Frost's" query, the weight of a cubic foot of ice at 32° equals 58lb. 1oz.—F. C.

[1170.]—Ice is somewhat lighter than water, inasmuch as it floats in that liquid. The specific gravity of ice is .926, that of water being unity; and if the weight of a cubic foot of water be taken as 1,000oz., the weight of a cubic foot of ice will be 1,000oz. × .926, which equals 926oz., or 57lbs. 14oz.—R. L. B.

[1176.]—WEIGHT OF CEMENT CONCRETE.—In answer to "T. T. W.," the weight of a cubic yard of cement concrete, as given by Molesworth, equals 3,591lb., or 1 ton 12cwt. 0qrs. 7lb.—F. C.

WAGES MOVEMENT.

THE operative plasterers of Leeds have served the following notice on their employers:—"We, the operative plasterers of Leeds, seeing that our trade in several of the neighbouring towns, likewise one of the building trades of Leeds, have the privilege of the diminution of the hours of labour, see no reason why the plasterers of Leeds should not have the same privilege; we therefore trust that you will take this into consideration, viz.:—For the first five days to commence work at seven a.m., and close at half-past five p.m.; and on Saturday to commence work at seven a.m., and close at half past twelve p.m.; to have meal hours as at present, the same to continue all the year round. Rate of wages—5s. 4d. for the first five days, and 3s. 4d. for Saturday. N.B.—We require the above to come into operation on the first Monday in May, 1869."

STAINED GLASS.

THE memorial window to Chaucer, immediately over his tomb in the south transept or Poets' Corner, Westminster Abbey, is intended to embody his intellectual labour and position amongst his contemporaries. At the base are the Canterbury Pilgrims, showing the setting out from London and the arrival at Canterbury. The medallions above represent Chaucer receiving a commission, with others, in 1372, from King Edward III. to the Doge of Genoa, and his reception by the latter. At the apex, the subjects are taken from the moral poem entitled "The Floure and the Leafe." "As they which honour the Flower, a thing fading with every blast, are such as look after beauty and worldly pleasure; but they that honour the Leaf, which abideth with the root, notwithstanding the frost and winter storms, are they which follow virtue and during qualities, without regard to worldly respects." On the dexter side, dressed in white, is the Lady of the Leafe, and attendants; on the sinister side is the Lady of the Floure, dressed in green. In the spandrels adjoining are the Arms of Chaucer. On the dexter side, and on the sinister, Chaucer impaling those of (Roet) his wife. In the tracery above, the portrait of Chaucer occupies the centre, between that of Edward III. and Philippa his wife; below them, Gower and John of Gaunt, and above are Wickliffe and Strode, his contemporaries. In the borders are disposed the following arms, alternately: England, France, Hainhault, Lancaster, Castile, and Leon. At the base of the window is the name Geoffrey Chaucer, died A.D. 1400, and four lines selected from the poem entitled, "Balade of gode counsaile."

"Flee fro the prees, and dwell with soth fastnesse,
Suffise unto thy good though it be small;"

"That thee is sent receyv in buxomnesse;
The wrastling for this world a-keth a fall."

This window was designed by Mr. J. G. Waller, and executed by Messrs. Thomas Baillie and George Mayer, 118, Wardour-street, London, 1868.

Two memorial windows of stained glass have just been placed in St. Peter's Roman Catholic Church, Belfast. The first window is represented by a local journal as "one of the most magnificent objects on which the eye could rest"—whatever that may mean. The other contains a representation of the "Last Supper." The windows are the production of Mr. W. H. Sullivan, of Liverpool.

STATUES, MEMORIALS, ETC.

THE Royal Mausoleum at Frogmore was visited by a large number of persons on Tuesday, and is now completed—the granite sarcophagus being placed in the centre of the floor of the building, with the marble recumbent statue of the Prince Consort, by the late Baron Marochetti, resting on its cover. The sarcophagus, which is of Scotch grey granite, stands upon a black marble plinth, with four bronze angels—also the work of Baron Marochetti—at each angle. The black marble is from Belgium, and is a gift of the late and present King of the Belgians. All that now remains to complete the decoration of the building is to place three more pictures and three more statues in the vacant niches.

A memorial tomb of grey granite, with red panels, is to be erected at Horrabridge, near Plymouth, to the memory of the late Sir James Brooke, Rajah of Sarawak. The sides of the tomb are to be filled with bronzes representing scenes in the life of the deceased.

LEGAL INTELLIGENCE.

A CIVIL ENGINEER NONSUITED.—This was an action at Nisi Prius by a civil engineer to recover £235 for professional services alleged to have been rendered to Sir Charles Fox and Son. The case for the plaintiff was, that in 1865 he suggested to Sir Charles Fox the formation of a railway between Lancashire and Cheshire, by means of a tunnel under the Mersey. Ultimately the defendants took up the scheme, and it was agreed between them that when the act of parliament was obtained he should receive £500 and be appointed resident engineer of the railway. The act was obtained, but in consequence of the commercial panic the undertaking could not be carried out. The plaintiff, however, received £500, and was satisfied with that payment. In October, 1866, an extension of the railway on each side of the river was contemplated, and the plaintiff said he was employed by the defendants to make surveys and plans for the additional works. The present action was brought to recover the sum he claimed for the services he had so rendered. The defendants denied that they were liable, on the ground that the plaintiff had undertaken the necessary surveys and the preparation of plans entirely on his own responsibility. The plaintiff was nonsuited.

CLAIM FOR COMPENSATION.—KING v. KELK, LUCAS, AND OTHERS.—ACCIDENT.—This was an action brought in the Court of Queen's Bench by the plaintiff, a house painter, to recover damages against the defendants, the well-known builders, for serious injury suffered by him in consequence of the alleged negligence of their servants. The defendants pleaded not guilty of negligence, and not liable for the consequences of the injury. It appeared from the evidence of the plaintiff that he had been previously to the accident employed as a house painter at Muswell Hill, and when in May, 1866, the work ceased, he went to the Alexandra Palace Hotel, where he heard work in his line was to be had. He was directed by a man in the defendants' employment the way to the office at which he was to make application, and while proceeding to it a man engaged on the works dropped, from a considerable height, a heavy iron chain, which struck plaintiff, knocked him down, and seriously injured his thighs and one of his feet. He was rendered insensible. When taken up he was placed on a stretcher and conveyed to his own home, where he was attended for some time by Dr. King, and subsequently by Dr. Llewellyn. He was subsequently received as an inpatient in the German Hospital; but from the time of the injury up to the present he had never been able to use his foot, and was disabled from pursuing his business as a painter. Witnesses having been examined on the one side and the other, and counsel for plaintiff and defendants having addressed the jury, the Lord Chief Justice summed up the evidence. The jury, unable to agree in their box, retired, and, after a considerable time, returned into court and gave a verdict for defendants.

Our Office Table.

Some observations lately made by Dr. Frankland tend to throw some light on the cause of the action and non-action of water on lead. He has found that water which acted on lead lost this power after being passed through a filter of animal charcoal. This, in his opinion, is owing to the presence of a minute quantity of phosphate of lime passing into the water from the charcoal. On comparing two natural waters, that of the River Kent, which acts violently on lead, and that of the Vyrnwy, which, though very soft, has no action whatever on that metal, he found that the latter contained an appreciable amount of phosphate of lime, while none could be detected in the Kent water. These facts would appear to bear out the Doctor's hypothesis, and may probably account for the discrepancy of evidence in reference to the action of soft water on lead.

The following paragraph is copied from an account of the Luther Festival at Worms, which appears in the *Jewish Herald* for this month:—"Several strangers who had come to the festival also visited the Jewish synagogue, which is one of the most ancient in Europe. It was built in the Gothic style, about 800 years ago, by one Mar Joakob. A lamp is kept perpetually alight before the Ark of Covenant, bearing this inscription, 'Eternal Lamp in Commemoration of the Two Wanderers.' It is said that during a persecution of Jews at Worms, 700 years ago, two unknown strangers, Christians, making a short stay there, were killed while trying to shield the Jews from the fury of the rabble. The names of these two devoted persons have never been known, but the grateful Jews of Worms sought to immortalise their memory by the foundation of an ever-burning lamp." Now, whatever the actual style may be, if the above account is correct as to date, the building must be an interesting one, and should any of your correspondents have the opportunity of procuring photographs of the outside and interior, the illustration of the same in the pages of the BUILDING NEWS would doubtless gratify many of your readers.—I am, &c., GEORGE MARTIN.

At the meeting of the Academy of Sciences at Paris on November 30, the Count of St. Cricq-Cazeaux proposed to cover the worn-out steps of the column in the Place Vendôme with thin sheets of aluminium bronze. M. Dumas approved of the idea, and reminded the meeting how successfully this bronze was now being used in various kinds of mechanism, especially in saws driven by steam power, which saws, although much thinner, lasted a much longer time than those of steel.

After thirty-eight days' trial in the Irish Court of Queen's Bench, a case, Doolin *v.* Dixon, between a builder and the Roman Catholic clergyman of Phibsborough, near Dublin, has terminated in a disagreement of the jury. The judge who tried the suit was Chief Baron Pigot, and the sum claimed by the plaintiff, £11,500, is said to be exceeded by the total of the legal costs on both sides.

A good many generations ago the then Earl of Derby obtained leave from his sovereign to build and fortify a castle at Liverpool. On more occasions than one well-executed subterranean means of communication between the castle and different points of the river beach have been discovered; none of these, however, surpassing in interest and distinctness one which has been brought to light within the last day or two in the area of the Exchange buildings. Here a deep excavation is being made for the cellars. In the course of this excavation, which is all through rock, a well marked gallery has been opened up. It is cut in the solid rock, is fully 6ft. in height by 3ft. in width, and its crown is about 6ft. below the surface of the natural ground. It runs almost directly north from the site of the castle, from which the Exchange is distant about 200 yards or more. It has been very carefully excavated, the tool marks of the excavators being very distinctly left in the rock.

On Thursday week the end of what is professionally termed "a silver medal year" of the Royal Academy was celebrated in the usual manner by the award of prizes to the students by Sir Francis Grant, P.R.A., in the lecture hall of the Academy, Trafalgar-square. Last year the most attractive competition was for the historical (gold) medal; on this occasion it was the competition for the travelling studentship that created the greatest amount of interest. "The Last Song of the Girondists," by Mr. C. Calthorp; a domestic picture described by the text, "The Lord giveth and the Lord hath taken away, blessed be the name of the Lord," by Mr. Frank Holl (son of the eminent engraver); and "Orestes Pursued by the Furies," by Mr. C. Rolt, were the competing works. The premium of £10 for the best drawing from the antique done during 1867 was awarded to Mr. Philip Westlake; the medal for copying to Miss Kate Aldham; the medal for the best painting from the life to Mr. Arthur Stocks, son of the eminent engraver; and the medal for the best drawing from the life to Mr. E. T. Haynes. The travelling studentship for the best architectural design of a museum for natural history was obtained by Mr. E. Marshall. The following were likewise awarded prizes:—For perspective and sciography, Mr. E. Block; drawing from the antique, Mr. W. Britten; antique model, Mr. T. Brock; life model, Mr. J. Carter; and for a restoration of a portion of the Parthenon frieze, Mr. T. Brock.

A correspondent informs us that the Gaiety Theatre, in the Strand, now nearly complete, and which will be opened on Saturday, December 26, is the only theatre in this country which has any pretensions to be fireproof. The pit floor, circles, galleries, corridors, and entrances are constructed with Messrs. Phillips' patent, a combination of their patent girders and ⊥ floor bars, forming a complete frame of wrought-iron, which is filled in with 6in. thick of Portland cement concrete. The under side of concreting is plastered, and the floors of corridors and entrances are formed of Portland cement, 1¼in. thick. The cantilevers supporting galleries are of I form, securely bolted to the columns and also into the solid brickwork of outer walls by stout tie bars. Every precaution has been taken by the architect (C. J. Phipps, Esq.) to ensure the stability of the structure in this respect. The works were only commenced in August last. Mr. Archibald Dawnay, C.E., has very ably carried out the ironwork, under the Messrs. Phillips.—[How can a theatre be called fireproof which is boarded all over inside? Possibly the skeleton of the new theatre is fireproof, as our correspondent says, but let a fire once break out there, and it will in all probability spread with amazing rapidity.]

The old town mansion of the Marquis of Salisbury is now being pulled down, and the site will be entirely cleared, and early in next year the new mansion will be commenced from Mr. W. Slater's and Mr. R. Herbert Carpenter's designs. One of the fronts will be in the Green Park and the other in Arlington-street. The block of buildings next the park will be a private residence for the family. The main block will include grand reception rooms, dining-room, and hall. Messrs. Lucas Brothers will be the contractors.

In reference to our note about Mr. Burges's chalice, a correspondent asks how it is that none of our churches possess church plate considered worth looking at, while the city companies plume themselves on their standing cups and other relics, and so do the Oxford colleges.

A correspondent notes, with regard to the proposed changes in the constitution of University College, that it is to be hoped they will be in a liberal direction, so far as architecture and engineering are concerned. As yet not one of the architect or engineer students has been created a fellow, or become a member of the governing body of the college. The proposed change of constitution is the result of a liberal action of the proprietary body. Some years ago the example was set of proprietors giving up shares to the council, who appropriated them to distinguished students under the name of fellows, thereby gradually converting the proprietary body into a constituency of graduates.

The works upon the Loughborough Park for the Suburban Village and General Dwellings Company, under the new management, are favourably progressing, giving promise of a speedy commencement of building operations. The roads have been marked out, and contracts for their construction, with sewers, &c., are being invited by the directors. The general arrangement of the estate is such as bids fair to secure, on its completion, a village capable of containing 7,000 inhabitants, who will have dwellings in every way constructed to secure domestic comfort and sanitary requirements. The efforts of the company are being appreciated by the working classes, its object being to help them without the sacrifice of their independence, and to secure them houses of their own upon better terms than many building societies. The scale of repayments extends over twenty-one years, at a smaller rate of payment than is generally asked for rent in the crowded localities of London. A selection of plots and class of house was made on Thursday, December 10, on which occasion all who had paid their calls or instalments according to priority of application had a choice, and about 100 were chosen, and will be taken possession of upon completion.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Society of Engineers.—Continuation of paper on the "Application of Steam to the Cultivation of the Soil," by Mr. Baldwin Latham, 7.30.

TUESDAY.—Institution of Civil Engineers.—Annual general meeting for the election of the council and officers, and for the distribution of premiums, 8.

WEDNESDAY.—Geological Society, 8.
Society of Arts. Description of the Electric Organ, by Henry Bryceson, Esq., 8.

Patents for Inventions

CONNECTED WITH THE BUILDING TRADE.

798. J. AND J. THOMPSON. FIXING DOOR AND OTHER KNOBS. Dated March 7, 1868.

Among the features of this invention are the following:—In order to fix a knob on each side of a door when the door is fitted with a mortice lock, the patentees form around the boss or stem of the knob a V or similar groove; the boss or stem of the knob is received into and fits in a recess in a rose or plate which is fixed to the side of the door by screws or otherwise, and, in order to retain the boss or stem of the knob within the recess in the rose plate, two or more screws or other projections from the rose plate enter the groove in the knob, the ends of the screws or projections being caused to bear against the inclined side of the groove nearest to the door; the knob is thus held up to the side of the door, or to the rose plate upon it, but yet is free to turn within the recess in the rose plate, a square hole or recess being formed through the centre of the stem or boss of the knob to receive the end of the lock spindle, as is usual.—Patent completed.

833. S. NAYLOR. APPARATUS FOR RAISING WATER. Dated March 11, 1868.

The patentee claims mounting a wheel driven by steam power, or in other convenient manner, and having blades or arms upon it, in a narrow chase or passage, and leading the water to be raised from the lower channel into such chase or passage at a point under the axis of the wheel, so that the blades or arms, in place of striking the water as soon as they reach the level of the water in the lower channel, may not come in contact with the water until they are travelling horizontally or nearly so. He also claims the use of a jointed floating valve or flap at the entrance to the upper channels to prevent the return of the water from the upper to the lower channel when the wheel is stopped. He also claims the general arrangement of apparatus for raising water, substantially as described. Patent completed.

859. S. HOLMES. SIGNALS [illegible] INTERCOMMUNICATION IN RAILWAY TRAINS AND B[illegible]. Dated March 13, 1868.

The object of the invention is the establishment of reliable oral intercommunication, for such a length of time as may be desired, between one particular compartment or place and that with which it is wished to communicate, and the invention consists in various arrangements, which we cannot here describe, for effecting this object.—Patent abandoned.

Trade News.

TENDERS.

B[illegible].—For [illegible] at [illegible] mill, [illegible] Hanstock, architects:—

[illegible]

K[illegible].—For [illegible] Messrs. Nash and Son, [illegible], architects:—

[illegible]

NEW [illegible] LANE.—For [illegible] Notley, architect [illegible]:—

Woodward	[illegible]
Webb and Sons	[illegible]
Newman and Mann	[illegible]
Lathey Brothers	[illegible]
Adamson and Sons (too late)	[illegible]
Myers and Sons	[illegible]
Turner and Sons	[illegible]
McLachlan	[illegible]
J. Motter	[illegible]
Browne and Robinson	[illegible]
Colls and Son	[illegible]
J. Thompson	[illegible]

Agreed between the lowest two that J. Thompson should withdraw in favour of Colls and Son.

ORE.—For erecting house and offices on St. Helen's Park Estate at Ore, near Hastings, for [illegible] W[illegible], Esq. E. Habershon, Brock, and Webb, architects:—

Manley and Rogers	£ [illegible]
Simpson	[illegible]
Scrivener and White	[illegible]
Patman and Fotheringham	[illegible]
Longmire and Burge	[illegible]
Nightingale	[illegible]
Longhurst	[illegible]
Hughes	[illegible]
Howell	[illegible]

OXFORD.—For the rebuilding [illegible] at the clothing factory of Messrs. Hyde and Co., clothiers, Oxford. Mr. C[illegible], architect:—

Baker	£ [illegible]
Dover	[illegible]
Jones	[illegible]
Castle and Co.	[illegible]
Hall	[illegible]
Cowley (accepted)	[illegible]

PENZANCE.—For [illegible], &c., at [illegible] Harbour, near Penzance. Quantities supplied by Mr. Joseph Simmonds. Mr. Douglas, engineer, [illegible] Works, Penzance:—

Robbins	£[illegible]
Havan	[illegible]
Freeman and Son	[illegible]
Sharps Brothers	[illegible]
Hibbard and Long	[illegible]
Moore	[illegible]
Keswick	[illegible]

SOUTHILL.—For erecting a warehouse [illegible] in Station road, S[illegible]hill, for Mr. [illegible] and Hanstock, architects:—

Accepted Tenders.

George Mallinson, Mason	£[illegible]
Petty and North, [illegible]	[illegible]
Jonas Thornton, [illegible]	[illegible]
J. H. Senior, Plumber	[illegible]
J. W. Hey, Plasterer	[illegible]
Total	£[illegible]

WHITE [illegible].—[illegible] for the [illegible] Mr. G. H. Smith[illegible]:—

[illegible] February [illegible] Walworth.

[illegible] a public hospital and dispensary. Premiums £[illegible], £[illegible], and £[illegible]. J. Barras, honorary secretary.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

LEWISHAM.—For the construction of six houses.—W. C. Banks, architect, 39A, Gracechurch-street, City.

UPPER MOOR, BODENHAM, HEREFORDSHIRE.—For the erection of new farm buildings, and alterations to farm house. F. R. Kempson, architect, 34, Castle street, Hereford.

LITCHURCH LOCAL BOARD OF HEALTH.—January 18.—For the execution of certain drainage works in this district. W. Whiston, jun., clerk to the board.

TOTTENHAM.—December 23.—For the formation of roads on the Coleraine Park Estate. Messrs. Hudson, Matthews, and Co., solicitors, 23, Bricklersbury, E.C.

KINGSTON-ON THAMES.—December 23.—For the supply of best blue broken Guernsey and China granite. J. Bell, clerk, District Highway Board.

KINGSTON-ON-THAMES.—December 23.—For the supply of grey pit flints. J. Bell, clerk to the District Highway Board.

RADNOR COUNTY GAOL.—January 7.—For alterations to this gaol. R. Banks, clerk of the peace, Kingston, Radnorshire.

MADRID (Spain).—January 20.—For the construction of tow markets. E. Petano, Charge d'Affaires, Spanish Legation, London.

HIGHGATE.—For alteration and additions to a villa. Messrs. Habershon and Pite, 38, Bloomsbury square, W.C.

ACTON.—December 22.—For constructing a sewer and other works in Church Fields road. E. Monson, C.E., surveyor to the board.

DERBY.—January 7.—For the erection of the new hotel and shops in the corn market, W. C. Watson, Derby Improvement Company's Office, Wardwick, Derby.

METROPOLITAN BOARD OF WORKS.—January 8.—For the construction and maintaining in repair for twelve months of a brick and iron sewer in Deptford and Rotherhithe. J. Pollard, clerk, Spring gardens.

CALNE (Wilts).—December 31.—For the erection of a detached villa at Bremhill, near Calne. John Watson, architect and surveyor.

NORTH-EASTERN RAILWAY.—December 26.—For the supply of timber, bar iron, plates, bolts, nails, &c. T. Cleghorn, secretary, Railway Offices, York.

NORTHAMPTON IMPROVEMENT COMMISSIONERS.—January 6.—For the construction of a culvert in Herbert street A. B. Markham, clerk to the Commissioners, 2, Derngate, Northampton.

LEOMINSTER.—January 6.—Great Western and London and North-Western Railways.—1st. For an iron bridge of two spans, with embankment, &c. 2nd.—An iron foot bridge, of 40ft. span. J. Wait, secretary, Birkenhead.

BACUP CEMETERY CHAPELS.—January 4.—For the several works required in the erection of three chapels. Gay and Swallow, architects, &c., Exchange-buildings, Bradford.

STOURBRIDGE.—December 31.—For the erection of a new church, at Stamber mill, near Stourbridge. Thomas Smith, architect, the Mount, Stourbridge.

PROPERTY SALES.

DECEMBER 8.

AT THE MART.—By Messrs. Driver.—Freehold residence known as Canterbury House, West end lane, Hampstead, with stabling, lodge, pleasure grounds and paddock, about 2½ acres—sold for £5,000.

Freehold plot of building land fronting Southampton road, Kentish Town—£120.

Freehold plot of building land fronting Southampton road, Kentish Town—£230.

Freehold house, situate at the corner of Southampton road, Kentish Town—£560.

Leasehold house, No. 78, Southampton road, term 81¼ years unexpired, at £5 per annum—£225.

Freehold two plots of building land fronting Southampton road—£220 each.

Freehold plot of land, with dwelling thereon, fronting Gospel Oak grove, Kentish Town—£315.

Freehold plot of land fronting Lismore road, Kentish Town—£570.

Freehold plot of land fronting Gospel Oak grove, Kentish Town—£120.

Freehold the Gospel Oak Schools, and plot of land in Circus road, Kentish Town—£1,400.

Freehold residence known as Bartram's Park, Haverstock hill, with pleasure grounds and paddock, about 2¼ acres—£5,500.

Freehold house, No. 2, Leighton road, Kentish Town, let at £32 per annum—£640.

Freehold house, No. 4, Leighton road, Kentish Town, let at £25 per annum—£550.

Leasehold house, No. 6, Leighton road, Kentish Town, let at £26 per annum, term 28¼ years unexpired, free from ground rent—£330.

Leasehold house, No. 8, Leighton road, term similar to above, free from ground rent—£330.

Leasehold improved ground rent of £16 per annum, for 28¼ years, secured on Nos. 10, 12, 14, and 16, Leighton road—£130.

DECEMBER 9.

By Messrs. E. Fox and Bousfield.—Freehold marine villa, known as Charman Dean, in the parish of Broadwater, Sussex, with stabling, offices, pleasure grounds, &c., containing 72 acres—£13,700.

Freehold residence, with gardens and meadow land, 20 acres in extent, known as Vine Lodge, Sevenoaks, Kent—£8,500.

Freehold house and shop, No. 262, Roman road, Bow, let at £38 per annum, subject to a mortgage—£60.

By Messrs. Hards, Vaughan, and Leifchild.—Freehold sugar estate, known as the Greenhill Estate, situate in the parish of St. Mary Cayon, in the Island of St. Christopher, containing 390 acres—£5,450.

Freehold piece of land, containing about 8,425 square feet, situate in the parish of St. George Basseterre, in the above island—£390.

DECEMBER 10.

At the Mart.—By Messrs. Wilkinson and Horne.—Leasehold house and shop, No. 2, Romsey terrace, Well street, South Hackney, term 80 years from 1865, at £6 per annum—£850.

Leasehold house and shop, No. 3, Romsey terrace, let at £45 per annum, term and groundrent similar to above subject to a mortgage)—£65.

Leasehold house and shop, No. 4, Romsey terrace, let at £45 per annum, term and ground rent similar to above subject to a mortgage)—£50.

Leasehold business premises, No. 15, Little Bell alley, Moorgate street, City, term 21 years from 1858, at £42 10s. per annum—£500.

By Messrs. Hards, Vaughan, and Leifchild.—Freehold house and shop, with warehouse and premises in the rear, No. 4, New Park street, Great Guildford street, Borough, let at £50 per annum—£860.

Leasehold four residences, Nos. 2 to 5, Cambridge terrace, Brockley road, Forest hill, annual value £45 each per annum, term 99 years from 1866, at £24 per annum—£1,500.

Leasehold house and shop, No. 31, Upper Marylebone street, let at £80 per annum, term 60 years from 1863, at £12 per annum—£940.

By Messrs. C. C. and T. Moore.—Freehold four houses, Nos. 109, 111, 113, and 115, Kerbey street, East India road, producing £67 12s. per annum—£510.

Freehold house and shop, No. 74, St. George street, St. George's East, let at £25 per annum—£260.

Copyhold ground rent of £36 per annum, secured on seven houses situate in Jamaica terrace and Robert street, West India road, Limehouse—£670.

Copyhold ground rent of £26 6s. 6d., secured on Nos. 3 to 7, Limehouse causeway—£920.

Freehold rental of £64 per annum, secured on the Eagle, Brewery, High street, Poplar—£1,320.

Leasehold two houses, one with shop, No. 13, Grenada terrace, and 4, Bermuda street, Commercial road East, let at £50 per annum, term 25 years unexpired, at £4 per annum—£370.

Leasehold two houses, Nos. 12 and 14, Martha street, St. George's East, term 22 years unexpired, at £5 11s. per annum—£120.

At Garraway's.—By Mr. George Berry.—Freehold eight plots of land in the Spencer and Milton roads, and a corner plot in Chancer road, Dulwich road—£750.

Freehold house, shop, and premises, No. 34, Church street, King's road, Chelsea, let at £30 per annum—£440.

DECEMBER 11.

At the Mart. — By Mr. Robins. — Leasehold residence, No. 33, Islip street, Kentish Town road, let at £38 per annum, term 81 years unexpired, at £8 8s. per annum—£360.

BANKRUPTS.

TO SURRENDER IN BASINGHALL-STREET.

Augustus Pickett, Thornton Heath, builder, December 31, at 12—William Skull, Lever street, St. Luke's, marble mason, January 11, at 1—William Wisher, Avenue road, Coldharbour lane, builder, December 30, at 12—Stephen Caslake, Hornsey rise, gasfitter, December 29, at 11—George Gilkes, Teddington, builder, December 24, at 12—Thomas Hughes, Arlington street, New North road, builder, January 11, at 12.

TO SURRENDER IN THE COUNTRY.

Joseph Greenacre, Yarmouth, carpenter and builder, December 23, at 12—Robert Hodgkinson, Birmingham, building surveyor, January 8, at 10—Griffith Humphreys, Corwen, builder, January 6, at 12—Joseph Rothuson, Brierley hill, carpenter, January 4, at 12—Ellis Cutlaw, Phillack, builder, January 5, at 11—Joseph Fish, Blackpool, bricksetter, December 23, at 2—Alfred Wilkinson Seymour, Manchester, joiner and builder, December 29, at 9.30—James Whatmuff, Brigg, joiner and builder, December 22, at 10.

NOTICES OF SITTINGS FOR LAST EXAMINATION.

January 11, E. Foley, Leyton, builder—January 11, W. Mackenzie, Colchester street, Pimlico, builder—January 11, J. Wheeler, Althorpe road, Wandsworth Common, builder—January 18, J. Squirrell, Portland road, South Norwood, gasfitter—January 12, R. B. Talbot, Stafford, builder—January 19, J. Gadd, Kensington place, Westminster, stonemason—January 19, C. E. Birt, East India road, contractor—February 1st, B. Chandler, Worth, builder—January 22, J. E. Ward, Plaistow, builder—January 22, J. Smith, Appleford road, Westbourne Park, stonemason—January 8, J. Conlson, Bolton, joiner and builder—December 23, F. Woor, Loddon, Norfolk, brickmaker—December 30, J. Buckley, Davenham, builder.

PARTNERSHIPS DISSOLVED.

Wood and Cliff, Huddersfield, painters and paperhangers—J. and J. Chadwick, Dodley, Yorkshire, stone dealers—Taylor and Armstrong, Birkenhead, ironfounders—Knight and Hebbett, Shorcham, builders—M'Clean and Co. Great George street, Westminster, civil engineers.

DIVIDENDS.

January 9, J. George, Orleton, Herefordshire, carpenter—January 13, W. Winch, Turin street, Bethnal green road, timber merchant—January 13, D. Dunham, Toddington, Beds, builder—January 20, T. Spooner, Burton-upon Trent, surveyor—January 8, J. Turner, Cheetham hill, builder—December 23, S. Gee, Burton-on-Trent, joiner—January 2, W. Eddy, Gosport, plumber—January 2, C. Bicknell, sen., Southsea, gasfitter.

DECLARATION OF DIVIDENDS.

S. Knight, Sittinghourne, carpenter, div. 1s. 9d.

THE BUILDING NEWS.

LONDON, FRIDAY, DECEMBER 25 1868.

THE "GRAND STYLE."

THERE are few things more generally distasteful than a pompous way of setting about ordinary matters. "All men," it has been said, "hate a formal fool," and Englishmen are supposed to carry this dislike of formality to a higher pitch than anyone else. In many respects this is undoubtedly true. People who talk in the manner of Mr. Micawber are sufficiently rare to be noteworthy, and the "grand style" in journalism finds little favour with the critics. But in architecture and its adjuncts the case is strangely different. We seem, speaking broadly, to have no style for every day—no architectural dress for common purposes. Our shops and warehouses are decked out with scraps from palaces and churches, or else built totally without regard to appearance; they fail to keep the desirable medium between rags and finery. Architects, as most of us must confess, too often act as if a plain design would be discreditable to them. There is too much anxiety to put all they know into every work, instead of giving to each so much elaboration only as best befits its purpose. The temptation is to be always seeking opportunities for cleverness, to put high art into a shop front, if there is no chance of doing so in a cathedral. A sort of general competition is always going on for notice and admiration—a strife as to who can outdo the rest, not in good taste and propriety, but simply in catching the public eye. Hence a building without ornament is almost unknown. We decorate everything, from banks to workhouses. We have no costume for the world to do its business and live its daily life in: we put all our clients alike into full dress.

Not the least unfortunate result of this rage for finery is that of its making beautiful forms repulsive through mere repetition. The most perfect types soon cease to please when copies of them meet the eye at every turn. Mr. Ruskin has shown how familiarity has brought the finest Greek ornament into contempt, and the same thing is taking place at this hour with Gothic detail. If our best appliances are thus degraded by vulgar associations, what is left to us when we wish to soar above vulgarity? What are we to use on grand occasions if we wear out the grand style for every day? There are purposes to which dignity and magnificence properly belong. Architecture, as well as literature, has its epic poems; but their stately language was never meant to be the common dialect of the streets. And even the highest efforts of architecture will lose their effect without the advantages of contrast. Where every word would be emphatic, there is no emphasis at all. If every part of a picture be in high light, nothing but flatness can result. Many things must be content with a subordinate place if anything is to be really prominent; and this is just as true in groups of buildings as in single ones. The best artistic effect arises here, as in many other cases, from the practice which ordinary good sense would indicate—namely, that of carefully adapting the architectural character of each work to its particular purpose. With all the elaboration of the new façades in the City, there is a singular absence of expression in most of them—a want of that "distinction" which in art, as well as in life, is more fascinating than any amount of mere cleverness. They are generally uninteresting in spite of all their decoration. It is quite possible, on the contrary, to combine great interest and individuality with simplicity and repose, and this is the ideal which one would wish for in the mass of town buildings. Let everything be well studied alike, but let the rhetoric and poetry of architecture, so to speak, be reserved for subjects on which they will not be out of place. We want good, plain prose, forcible and not inelegant, for matters on the level of ordinary existence. The ideas may be original, but the language should be unpretending. Unfortunately the exact reverse of this would fairly describe the prevailing fashion. The underlying idea—their "motive"—is commonly poor and shallow enough, but the mode of expressing it stilted in the extreme. There is almost no quiet beauty to be met with—no repose; every new building wants to be a salient point. One thinks instinctively of the advice given to the musicians in one of Longfellow's dramas—to play "with a certain modesty, and not as if each instrument were the only one in the universe." Harmony is impossible while every part aspires to be the leading one.

The misuse of the "grand style" is confined to no particular school, though it would be easy to specify some distinguished names on the Gothic side from which it has never received any support. But the truth is, this fault is prevalent in all quarters, though in all, perhaps, some happy exceptions may be found. M. Romaieu's recent work in Eastcheap, and Mr. Wilkinson's offices of some years back in Bishopsgate-street, fairly exhibit its mediæval development. The Crown Insurance Office in Fleet-street, too, is rather an advance in ornament than in art over Mr. Woodward's original design in New Bridge-street. Amongst buildings of the Italian type the difficulty is to select examples of the vice out of the multitude which present themselves. This style falls so naturally into the rigidly uniform mode of composition that most people hardly suppose irregularity to be admissible in it; and uncalled for uniformity—as much as excessive decoration—is a mark of too ambitious a method of treatment. It is only in works of a monumental class, if at all, that symmetry of arrangement should be followed as a primary object. In buildings of a lower order the natural course is to set convenience altogether above external display; and this leads nearly always not to exact symmetry, but to unaffected picturesqueness. Instead of giving a long list of new designs remarkable for inappropriate showiness, it will be more pleasant to notice a few in which better taste is manifested. The Provident Life Office in Gracechurch-street, by Mr. Kerr, though elaborated quite up to the point which its purpose would seem to warrant, has a sort of refinement and quiet elegance throughout which puts it in a very different rank from most of the surrounding architecture. The office of the General Assurance Agency, too, in the same street, though simple, is well studied and effective. Some of Mr. Blomfield's designs, again, to mention no others on the Gothic side, contrast very favourably as regards propriety of treatment with those referred to just now. The narrow frontage of the Post Office in Chancery-lane, and the premises built for Messrs. Heaton, Butler, and Bayne, are extremely free from the exaggerated architecturalism under notice. Perhaps, in the latter, at least, the tendency is almost to the opposite extreme, to a manner scarcely architectural enough for the streets of a great city. This, however, is at least erring on the safer side, and may help, as far as it goes, to oppose the popular idea that in Mediæval work everything is sacrificed for the sake of effect. Popular ideas often express themselves very absurdly; but the absurdity should not make us overlook any grain of truth which may lie at the bottom of them. When a competition committee advertises that Gothic designs will not be received, they are doing a very foolish thing, but doing it, in all probability, with a very excellent intention. The Gothic with which they are most familiar is that of some third-rate district church or Congregational chapel, and, like sensible men, they feel its childishness and unreality. They do not know that Gothic can be—and in good hands is—the most simple, natural, and unaffected way in which we can build. To them the name only suggests buttresses, tracery windows, gablets, and carved foliage, endless angles to run against, and the awkwardest of winding staircases. This sort of masquerading dress does not strike them as being the most appropriate thing for their new building, and so, to avoid it, they forbid Gothic altogether. Under existing circumstances, one cannot blame them very severely for the mistake. It only shows that the "grand style" in its Mediæval guise is felt to be even less appropriate to common matters than in any of its other forms.

MESSRS. WALFORD AND DONKIN'S ART FURNITURE.

IT is gratifying to see the attention of architects increasingly given to the amelioration of that "household taste" the lamentable condition of which is deplored so feelingly in Mr. Eastlake's recently-published work. We therefore gladly welcome all earnest efforts of volunteers for this somewhat forlorn hope; the more so because we fear they must in most cases prove the artist's sole reward, and that any very profitable return for the labour and thought expended is hardly to be looked for. As fresh labourers in this arduous field, and entitled to a share of its hard-earned laurels, we would recognize Messrs. Walford and Donkin, who have for some time been engaged in developing a style of furniture which has considerable originality and many merits. The character of the specimens of furniture represented in one of our lithographic engravings, and of other designs of theirs which we have seen, is sufficiently peculiar to deserve notice; and, although we cannot give it our unqualified admiration, we think it successful in many ways. Considering the acknowledged difficulty of the task they have set themselves to accomplish, we are not disposed to be hypercritical, but rather to look forward to the result which we believe they will be able, with further experience, to attain. The claims set forth by the authors for their style are sufficiently bold. They profess to provide "economy, comfort, and art as applied to modern domestic furniture"—an intention which, if fully carried out, ought to command the appreciation of the public. This is, however, a stiff-necked generation, and it does not always respond, even when piped to in the sweetest strains. We shall endeavour to see how far the promises thus held out have been, or are likely to be, performed, and to judge whether it will in this case be the architects or the public who are to blame if their effort prove not so successful as may be desired.

Among previous would-be reformers of our "household taste" some have adopted a far less comprehensive programme to begin with. High art has been their Alpha and Omega, and neither economy nor comfort have been objects they sought. To provide for comfort they have scorned, as pandering to the luxurious vices of the age. Sackcloth, embroidered it is true, has been the only class of material the use of which they would allow; and dust, il garnered in deeply crannies of carvings, they would not abhor. Plate glass has been gravely asserted to have been the invention of the Evil one, as a punishment for the special sins of the day, and elegance to have been a modern emanation from the same source. That the voice of such prophets should be disregarded is only what they looked for, and they have the crown of their martyrdom to solace them for their failures. Economy cannot be said to have been the aim of the designers of the painted furniture in the Mediæval Court of the Exhibition of 1862, and stories of "the wines and the beers"

richly dight on sideboards are not addressed to every-day purchasers.

However incumbent it may be upon a rightly educated public to delight in furniture put together in the true and orthodox rabbit-hutch style, the fact is that manufacturers of such wares must count upon a very limited, even though a highly select set of admirers. The recent collapse of the "Art Furniture Company" must, we think, be partly attributed to a praiseworthy resolve to teach rather than to please their customers. The object of Messrs. Walford and Donkin is more practical, if less enthusiastic and lofty-minded. The mediums through which they propose to work out art decoration are principally fret-cutting, stencilling, incising, and turning.

Fret-cutting they recommend as particularly adapted for clear and vigorous outlines. Elaborate subjects are executed by it with precision and facility, and it affords an incomparable saving over its sister art of carving.

Stencilling they advise as a substitute for parquetry and inlays, as being more readily worked by anyone who can cut a pattern or handle a brush, and by it the boldest relief is obtainable with the colours introduced.

Incising they propose to use for outlines; and by *turning* they endeavour to secure the delicacy and refinement for which it is especially adapted; and by the use of these cheaper modes of decoration they hope to bring art within the reach of the public.

We presume that it cannot be contended that any of the above processes are altogether novel even in their application to furniture. At the same time they have not been hitherto extensively used in the same manner, and consequently we have to thank these gentlemen for pointing out to us the capability of the tools we have at our command. It is, however, with the workmanship rather than with the tools that we are concerned, so we shall proceed to consider the application they have made of them. The style they have adopted must be called an eclectic one. It is mediæval so far as it is based on common-sense principles and construction unconcealed, although as regards what are called *shams* they profess themselves somewhat latitudinarian. Their qualification of such is that they should be "legitimate," and on this point they say, "We should not be inclined to quarrel with plaster or paper because our walls happen to be brick. In the same way we should not scruple to paint, print, or stencil patterns on panels, because the art of inlaying might be considered the older of the two, and the former, therefore, only an imitation. We, however, do not hold that articles made of wood should be turned into pure gold or tortoise shell, or so enveloped in leather or padding as to hide all construction or the position of their bones." Leaving them, however, to adapt these matters to their conscience, or their conscience to them, as in some of their battles with their cabinetmakers, they may find it necessary to do before they can finally settle, to the mutual satisfaction of both parties, all questions as to veneering and such like—we notice that the *motif* for much of their ornament is taken quite as much from Classic as from Gothic work, and we could wish these were its only sources, for neither of those pure styles would be glad to father the balusters which seem to creep into most of their designs, and from which we could well spare them. The objects upon which, as yet, they seem to have devoted the most pains, and with the greatest success, are their chairs, and a description of some of these will convey a tolerable idea of the character of their work. One armchair, seen, but not very favourably represented, in the illustration, does, to our mind, combine economy and comfort with no mean degree of art.

Each side, including the legs, is cut out of a single plank of birch, 22in. wide and 1in. thick, and the seat and back are composed of strips of the same wood ½in. thick, with their tenons piercing the sides and secured with small pins. The sides are perforated by fret cutting in a design, which, by a few incised lines, is cleverly made to represent two Scandinavian looking monsters armed with shields and engaged in a combat, and the upper terminations are cut and engraved as eagles' heads. Some delicate lines, like bars for music, and an octofoiled circle, simply sunk by a centre-bit, give relief to the part below the seat; the top of the back is also perforated and decorated in a similar manner. The chair is provided with a loose cushion and a pad nailed to the back and a fringe to the front of the seat. A round bar of wood connecting the back legs completes the construction.

The perforated decoration is open to the same objection as that of the carved work of the Bombay chairs, as affording a harbour for dust, and the position of the pad on the back is quite wrong, but this might be easily altered. The whole conception is, however, good, and affords ample scope for variety of design, while the cost of the chair, compared with its effect, must certainly be considerably less than those ordinarily sold.

Another chair without arms deserves remark. One piece of wood, 1½in. square, forms the side of the back and front leg, and a similar piece forms the back leg, and meets the other above the seat, giving it support just where it is wanted. These are both decorated with turning and gilding in a refined and delicate manner, and are connected together, and with the seat, by shaped pieces of board. A half-inch perforated board forms the top of the back, with a stuffed panel below finished with fringe. This chair is strong and firm, and it is constructed and decorated upon proper principles; it requires, however, a different slope of the seat and shortening of the legs.

Among the other articles of furniture is a sideboard, which invites comment, and curiously, we should say, both praise and censure in an equal degree—the former being confined to the lower portion and the latter to the part above. In fact, while we admire without much qualification the circular pedestals and the drawers which connect them, we should consign to the *Athenæum*'s "limbo of gew-gaws" the semicircular glass panel and all its appurtenances, which defy both description and criticism. This sideboard is executed in black wood, delicately relieved with incised and flat-fluted work and bold metal hinges, and has a very suggestive band of decoration representing in gilt lines a Greek four-horsed chariot and driver. This idea is the one which best supports the claim of the designers of the introduction of art into their work, and though we should prefer subjects not quite so far-fetched, we cordially appreciate its *motif* and its treatment.

For a table introduced into the foreground we cannot find a word of praise, as its only feature is the support, consisting of three nondescript balusters, with hardly less objectionable brackets and feet. The perforated sides of the bookcase worked into scrolls of foliage and birds, and a bold if somewhat eccentric cornice, are its best features, but we could not remain content with the lower portion till we had planed the bulging contours of its ends. The above description will, we hope, convey some idea of their meritorious attempts to effect an improvement in a direction where it is much needed. We hope that Messrs. Walford and Donkin will meet with many opportunities for developing and improving their ideas of domestic furniture, the originality and vigour of which we fully recognize. We should advise greater reticence in the use of notching and chamfering, and a higher development of the artistic element in their work.

The designing of furniture differs materially from the ordinary work of an architect, and demands some special training. There are certainly not many architects who would be competent, without considerable apprenticeship, to undertake it, and few who can find sufficient other professional employment would care to do so, for it is a difficult and profitless task, although an interesting one. We hear a great deal about the duty of architects to meet the requirements of the day, and we are not among those who think it incumbent upon them to denounce such on every occasion; but it is a far easier task to ring any necessary changes which climate or fashion may demand in a building than it is in its minor fittings and furniture. Precedents exist in almost all styles for any variety that can be asked for in the structure, whether it be in the number and size of its openings, affecting its proportions or otherwise; but to satisfy the claims of taste, and to fit at the same time the whims and the backs of men, women, and children, is a task not altogether to be envied.

It will not do to assert that whims ought not to exist, or that people's backs should be made to suit themselves to the chairs that have been designed for them upon purely high-art principles. Architects who undertake such work will find that they must set aside many of their preconceived ideas, for the same rules that they have been accustomed to apply to buildings will not be applicable to furniture. New problems, as it were, will present themselves for solution every instant, and without a thorough mastering of the details of this class of work, there can be but small hope of any successful result.

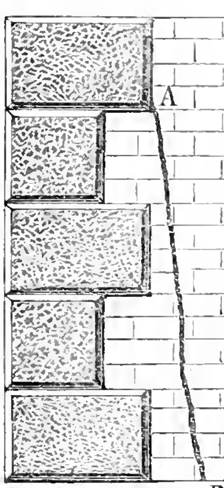
DEFECTIVE CONSTRUCTION OF MASONRY.

IS it a fact that we are rapidly losing the art of building in masonry, and that the days of bricks and mortar are fast passing away? From the specimens of the latter description of work that are daily springing out of the ground like mushrooms, it must be confessed that they bear not the slightest resemblance to the examples that have preceded them. There is not a week that we do not hear of some bridge, viaduct, or house falling down, and to no other source of weakness and instability can their downfall be attributed than to that of defective work or bad materials, and frequently to both these causes combined. Moreover, it is not at home alone that we are to look for these constructive catastrophes. They are quite as plentiful abroad—in Asia as well as in Europe; and, what is worse, in our own Indian possessions, and on railway works superintended by English engineers and constructed by English contractors. On the Great Indian Peninsula line, a number of bridges and viaducts have recently either altogether failed or manifested symptoms so serious of approaching dissolution and collapse that it was considered preferable to pull them down than to allow them to perform that operation for themselves. The report presented to the company of the line alluded to by their chief engineer is well worthy the attentive perusal of everyone engaged in the erection of structures of masonry and brickwork. Allowing for defective materials, bad mortar, and occasional "scamping" on the part of the native sub-contractors and overseers, the failures one and all are stamped with this inscription:—"To ruin were we brought by unequal settlement." From the earliest times of construction there has invariably been this obstacle to be overcome in the employment of separate and distinct materials—viz., the different manner in which they may behave under similar circumstances. It is often assumed that they will, so to speak, act together, or that, even if their action is not identical, it will be so insignificant in diversity of influence that there will be no necessity for taking any precautions to guard against unforeseen contingencies. The fallacy of this assumption and the disastrous consequences that attended the neglect of precautions was fatally demonstrated by the failure of several of the early railway bridges,

where an injudicious combination of cast and wrought iron was employed.

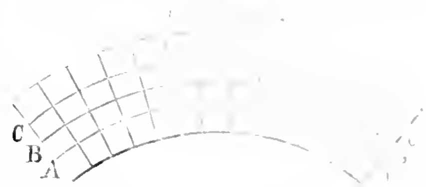
To return to the unequal settlement of masonry and brickwork. This may proceed either from employing two different descriptions of material in the same structure, such as stone and brick, or by using two or more varieties of work. If a wall, a pier, the abutment of a bridge, or a house, be built entirely of brick, there can be no unequal settlement take place, unless the foundation yield, which is a condition we shall not take into consideration at present, as that would be sufficient to cause cracks in the best structure ever erected. But if a structure be erected partly of brick and partly of stone, then, if the two materials be very unequally distributed and badly bonded together, there is considerable likelihood that there will be a settlement, originating in the vicinity of their union, and spreading gradually over the entire building. Let us take as a general illustration of our meaning the example in Fig. 1,

FIG. 1.



where the structure is of brick with stone quoins. The absolute difference of settlement between the two materials depends obviously upon the much greater number of joints that there are in the brickwork compared with the stone. As the mass of the brickwork settles, it shrinks away from the stone faster than the latter can follow it, and occasions a crack that will resemble that represented in the cut. The line of crack or "thread," as it is technically termed, will start somewhere in the neighbourhood of the bricks that lie vertically between the quoins, and which cannot settle to the same extent as the others; these will, therefore, be split across by the weight of the rest of the wall pressing upon them. Another fruitful source of the collapse of piers and abutments in which two classes of work are used is the want of bond between the facework and the "hearting" or filling. It is manifest that, if the bond be insufficient, the facework is nothing more than a mere veneering, and the least inequality of settlement would cause the face to sheer clean off from the rest of the structure. There would be, in fact, almost a complete "straight joint" between the exterior and interior of the work. It appears that the employment of two different descriptions of stonework in the face and backing of the piers and abutments of the viaducts in India was the chief reason of their collapsing. Manifestly, too great care cannot be adopted in bonding in uncoursed or rubble work in the backing with coursed ashlar work in the face. If the stones in the face be all stretchers and no headers, then there is no union between the face and the interior, and the structure as a whole is defective, unsound, and unreliable.

Many of the works alluded to were provided with wrought-iron superstructures, but others supported arches of masonry and brickwork in the ordinary manner. To the use of bad mortar, large joints, and inferior workmanship may be attributed the downfall of many of these. A glance at fig. 2 will



demonstrate the necessity that exists for small joints and mortar of the strongest and most adhesive description whenever, as is commonly the case, the arch is turned in half-brick rings. There is clearly not the slightest vertical bond or connection between the separate rings. The curved lines A A, B B, C C, represent complete concentric straight joints, and we could easily imagine the ring A A separating or dropping away from the other three while they remained sound and intact. An additional evil of this method of building arches is that unless the bricks be "gauged" the difference between the circumference of the intrados and the extrados must be made up by the joints, which in itself is a direct incentive to bad work. The perfection of an arch would be found in its being all in one piece, and, next to that, the depth of its voussoirs or rings should be equal to the thickness of the arch, a condition usually fulfilled in stone arches, but never in brick ones, excepting, of course, in such insignificant instances as window-heads and door and relieving arches. It is fortunate for the progress of engineering works abroad that we have made so extensive a use of iron, but, at the same time, it is neither sound nor economical policy to be compelled to employ it in situations where there are abundant materials for introducing a more solid and permanent type of construction. The proper use of iron is to employ it and make it available where other means for effecting the desired object cannot be obtained, but not to use it to the prejudice of more substantial materials simply because there is a difficulty in getting them put together so as to constitute sound and durable work. It has become so much the custom to build in iron that structures are often erected of that material in situations where masonry and brickwork could be employed at a much less cost, and with greater advantages with regard to correct æsthetical principles.

PROPOSED SEWERAGE OF GLASGOW.

EVERY practical man is ready to admit in the fullest sense that, although the sewage of London is not utilised to the extent it ought to be and could be, yet it is removed from the immediate vicinity of the metropolis in a manner which leaves nothing to be desired on the score of health, rapidity, and sanitary considerations. That other large cities and towns should follow the example of London with regard to getting rid of the offensive matter from the habitations of men is only what might be expected, and that they should, in addition, provide measures for effecting its ultimate utilisation might likewise be reasonably anticipated. From the fact, as expressed by some unreflecting rustic, that "it is very extraordinary rivers should always flow by towns," the utilisation of sewage is nearly invariably connected with the purification of the rivers, streams, or watercourses into which it was previously discharged with all its fœtid impurities. The whole problem of the utilisation of sewage is summed up in the phrase, "Take it out of the rivers and put it on the land." Simple as this proposed remedy may appear, it is not equally simple when attempts are made to carry it into practical execution. Nor, strange as it may seem, is every professional man agreed upon the propriety of the step. We should be quite prepared to allow for differences of opinion as to [illegible] respecting the [illegible] practically executing the principle we [illegible] that the absolute advisability of applying sewage to land is disputed. That the only effectual method of [illegible] its application to the soil, we regard as a truism confirmed by experiment and established by experience.

To return to the immediate object of our article, there are several plans proposed for the utilisation of the sewage of Glasgow, involving incidentally the purification of the Clyde. The only one of these which offers any real and practical solution of the difficulties is that of Messrs. Bateman and Bazalgette, who propose to utilise the sewage in the proper sense of the term, as understood by every engineer who has had any experience in this limited and novel branch of the profession. The proposal of Mr. [illegible] to create an artificial double current up and down the river by dividing it into two parts by a longitudinal wall, makes matters worse as it converts the Clyde into a double sewer instead of leaving it as a single one. Moreover, the scheme would totally spoil the appearance of the river, and is one which, in our opinion, has not a single redeeming feature. Mr. Scott proposes to purify the Clyde by bringing a quantity of sea water up to a certain point, and discharging it into the polluted stream. This is equivalent to a man first putting a dose of prussic acid into the water he is about to drink, and then diluting it with an enormous amount of water to prevent it killing him on the spot. We should be inclined to assert that the preferable plan would be not to let the poison get into the draught at all—in other words, not to let the sewage into the Clyde, and thus fulfil the ancient adage "prevention is better than cure," bearing in mind that we altogether deny that any cure of a polluted river would be effected by simply diluting the noxious impurities it contains. It must not be supposed that we ignore the purifying action of large quantities of water, or that, theoretically, a given amount of sewage would not be rendered inoffensive by the addition of a certain amount of water; but practically to apply this principle upon a very extensive scale, and also continuously, is a point we do not for a moment concede. In addition, all these projects are suicidal, and that is quite sufficient to stamp them, in the present age of *[illegible]*, as unworthy the adoption of a provident and thrifty people, who believe that by proper means and a due exercise of skill and care they may prove universally that nothing should be wasted. Undoubtedly at present we know little or nothing about the scientific management and utilisation of sewage, but time and experience will develop all that is required upon this point, so long as we remain true to the system we have adopted. One thing we are thoroughly acquainted with, that in adopting the utilisation of sewage by its application to land we have chosen the right path, and are daily acquiring knowledge which will enable us to perfect those details and subsidiary features which at the present, from our limited experience with respect to the whole [illegible], could not be anything else but crude and imperfect. But, on the other hand, if we once stray from the right path, if we once desert the principle that we know to be the only sound and correct one, then we are voluntarily refusing the good and choosing the evil, and must not be surprised if the end we attain is incommensurate with the means employed, and if the goal which we arrive is one not of reward but of punishment. And such will unquestionably be the result if, instead of adhering to the established truism we have laid down, and the principle recognised by the most eminent engineers as the only sound and reliable one, we allow ourselves to be diverted by other projects

which but imperfectly remove the sewage, but partially purify the contaminated rivers and streams, and effect no utilisation whatever of the fertilising material.

HOMERTON FEVER AND SMALL-POX HOSPITALS FOR THE METROPOLITAN ASYLUM DISTRICT.

THE committee invited six architects to compete for the above hospitals, and designs have been received from Messrs. Watson, Knightley, Bracebridge, Wilson, Scott, jun., and Giles and Biven, and it appears from the several plans that the requirements have generally been observed.

The style of the design submitted by Mr. Watson partakes somewhat of the ordinary house building with a few Gothic features. In the plan the kitchens are placed in the basement, and cleverly arranged to supply the general building. The entrance buildings have passages badly lighted, and it does not appear that the shape of this building is well arranged for its purpose, the squarer forms displayed in some of the other designs being preferable. The system of one corridor for each sex, divided in the centre by means of a blank wall, appears to us objectionable, the classes being brought too close together; and the ventilation impeded. The dormitories have one great fault, and that is the position of the bath, which being at the end destroys the advantage of having this part of the room well lighted. One day-room for each class is provided. This cannot be sufficient. Generally, this plan contains many points of merit, and might be greatly improved by further consideration. The estimated cost for both buildings is £42,700.

Mr. Knightley gives a very fair design of Italian character, and perhaps it may be said quite equal to any exhibited. The entrance building of this plan is well arranged, being somewhat square in form. The dormitories are well arranged, and separated from each other in a manner beyond that of any other competitor. The day-rooms are too far removed from the dormitories, and the special wards in main corridors must be objectionable. The intermediate dormitories are only one story. This plan increases the amount of air space. The minor portions of this plan have been well considered, and the kitchen, laundry, and other arrangements are satisfactory. The estimated cost for both buildings is £33,000, a sum we consider not sufficient for the work proposed.

The design by Mr. Bracebridge does not indicate the amount of skill displayed by some of the other competitors. The style is of a very plain character, and has not, perhaps, had sufficient attention, probably on account of its being secondary to the general arrangement. The entrance block is badly lighted, and all the offices seem to be small in their dimensions. The dormitories are very objectionable on account of the day-rooms being at the end, and the approaches to nearly all the ground floor dormitories are beneath the staircases. The estimate is £51,500, and we should think that the committee ought to have a much better building for such an outlay.

Mr. Wilson appears to have devoted considerable time to the preparation of his design; it would have been much to his advantage if he had confined himself to the preparation of one design. The style may be termed Italian, and the plan possesses some merit in the administrative department. The dormitories have no day-rooms, and the nurses' rooms and scullories are badly placed; the passages and corridors are not properly lighted, and many alterations are required to make this plan suitable for its purposes. The estimated cost is £41,350.

Mr. Gilbert Scott, jun., presents a design that may be considered somewhat French in character. The plan of entrance is good, and well arranged for lighting. The dormitories are well lighted, and the water-closets are well cut off from the several dormitories. A day-room for each dormitory has been provided; the position being in the angle is very objectionable, and it must be a miserable apartment. The kitchen and offices of this plan are placed in the basement, which appears to be a very unsatisfactory arrangement. Generally, this plan does not display the same knowledge as that shown by some of the other competitors in many minor accommodations and arrangements; and without such provisions the plan would be wanting in many essential features. The cost of the building is £64,000, and, considering that the arrangements are scant and the architecture of the plainest description, the estimate is too much.

Messrs. Giles and Biven have an alternative plan, which is inferior to the others submitted. The design is Italian and of fair character. The entrance buildings are small, and might with advantage be increased. The kitchen is in a bad position, being in the centre of the main corridor; other offices in connection therewith being placed on the opposite side. This arrangement is improved upon in the plan of the small-pox hospital. The wards for contagious diseases are very objectionable as to their position, opening as they do upon the main corridors. We expected something beyond this production from the authors. The cost is estimated at £44,000.

In reviewing the several plans we are not satisfied that either design is of sufficient merit as it now stands to be erected. It must be a matter of regret to find that, considering the amount of the highest estimate, the remuneration is little above 2½ per cent.; and all members of the profession must have reason to lament that so many will give so much labour for a payment so inferior to a fair charge. It will be remembered that this subject was enlarged upon at the opening meeting of the Institute, and it is sad to meet with such a result as displayed in this competition.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE usual meeting of the Royal Institute of British Architects took place on Monday night week, Mr. Joseph Clarke, vice-president, in the chair. A paper was read by Professor T. Hayter Lewis, F.S.A., Fellow, entitled—

NOTES ON THE CELTIC, ROMAN, MOORISH, AND OTHER REMAINS IN ALGERIA.

Professor LEWIS commenced by briefly describing the town of Algiers, and the districts round it, which comprised the district he intended to describe. Algiers itself was best known as a nest of pirates, but years ago Northern Africa was occupied by nobler races. Their descendants still form a large portion of its population, and are known under the name of Kabyles—in early history as Berbers—and are supposed to have been a branch of one of the Semitic nations of Asia. Of their architecture the Professor had nothing positive to say, but he called attention to some few specimens of an art still practised among them, many of which were of singular beauty. They were very peculiar, being worked chiefly on a base of white metal, on which a pattern is raised by thin lines of the same metal, precisely in the manner of Cloisonné enamel, but in such a manner as clearly to show that it was without the intention of filling it up. Some portions were, however, filled with delicate enamel or corals, chiefly of green or red, arranged with such skill as to produce a rich yet delicate effect. Some specimens of this work were exhibited in the Algerian collection in the Paris Exhibition of 1867, and the best of them have been retained in the present Government museum at Algiers. Their pottery also, though rude in shape and primitive in colour, offered no mean examples of the art. The Professor noticed at some length the successive occupations of Northern Africa by the Carthaginians, the Romans, the Saracens, and the French. Of the various works of all these peoples he would notice first those usually termed—for want of a better name—Celtic or Druidic. Of the rudest class of these he had found abundance near Algiers on the margins of a deep ravine of the Sahel, near the modern French village of Guyotsville. They were simply cromlechs similar to those at Kits Coty House, near Maidstone. They were formed of large rude unworked stones set up edgeways so as to make a small chamber, which was covered with one or more large flat stones at top. That these were sepulchres there was no doubt, from the presence of bones in all of them when newly opened. The most common articles found in them were flint implements, and no trace of a tumulus had been found over any of the cromlechs. No mark of a tool had been found by the Professor on any of the stones, and the only idea suggested of their origin was that they were the burial-places of an Armorican legion from Brittany which was known to have been located in Northern Africa. More curious remains of these early races, whatever they were, were to be found in the eastern province at Djebel Karonba, and these seemed quite peculiar to the country. Circular on plan, with an external diameter of about 20ft., they had thick external walls of good large rough coarse stonework, and were covered with flat stones in oversailing courses. They bore no mark, and possessed not even a tradition to tell of their authors or date.

Twelve miles west of Kiloa, 850ft. above the seashore, is the famous Kbour-er-Roumia, or Tomb of the Christian Lady. This monument is 200ft. diameter, on a platform 210ft. square; and on this is a circular range of engaged columns, projecting rather more than three-fourths of the diameter. They rest on bold mouldings, which, with their bases, remain pretty perfect. The bases are the well-known attic, and above them the shafts are continued to about 16ft. or 17ft. in height. Thence the exterior is destroyed. But, at about the height at which we should expect to find the blocking course above the cornice, a series of gradini commences, ending with a level platform 13ft. in diameter. At the four cardinal points are four false doorways, with panelled doors, having bold architrave mouldings, all the upper parts, however, being broken away. The shafts are Ionic, boldly but coarsely worked, and the carving of the capitals coarse and untrue. The tomb is so immense as to render it a certainty that it must have been built to enshrine some precious corpse, but, though effort after effort has been made by the French, no trace or skeleton, sarcophagus, shrine, or sepulchre had been discovered. As to the date of the work, the whole of the details gave one the idea of their having been copied by Roman artists from Greek originals, and this was the opinion of M. Berbrugger, who assigns the structure to Juba II., who died A.D. 19, and to his queen Cleopatra, daughter of the celebrated Egyptian.

Of a similar type to this is the Medracen, in the eastern province near Batna. The general description of the Kbour applied to this. It is, however, in a much better condition, except in one place at the entrance. The monument is 184ft. diameter to the projection of the cornice, 16ft. 5in. high to the top of the cornice, and 60ft. 6in. to the top platform from base. The top of the platform is 39ft. diameter. Between the columns outside are long ranges of sculpture, too decayed to allow of their being assigned to any peculiar style, though the subjects are to be made out. They represent the elephant, hyena, and other animals, but nothing had yet been done towards deciphering the meaning of these strange decorations. The most probable idea of the date of this monument seems to be that it served as a royal mausoleum for the kings of Numidia, and that it was built in the reign of King Syphax, who was sent to Rome B.C. 203.

Somewhat similar to the above, but of square outline on plan, are those known as the Djedav, in the south-east of the province of Oran, discovered in 1842. They are three in number, built of large stones on a square base with a pyramidal top formed of steps, as in the Madracen and Kbour. The perpendicular part at bottom is 112ft. square and only 11ft. high. Above are 12 steps 11ft. high in all, and all this is of squared large stones. Above the steps is a kind of pyramid also 11ft. high, and made of rude stones, as though broken or unfinished. One only of these structures has been opened. The entry was from the south-east, at some distance above the perpendicular part, and descending at an inclination of 25 deg. to a gallery running round three sides of the building, and having seven branches leading

out of it apparently for burial. The dates of these works are also unknown. Arab historians state that the Djedar were found during an expedition by the Calif el Mansour, who saw on a stone in front the following inscription :—"I am Solurian the Serdegos (strategos). The inhabitants of this town having revolted, the king sent me against them. God assisted me to conquer them." From some fragments of an inscription since found, the story seems to be authentic. Solurian was the Byzantine general who succeeded Belizarius, but the form of the monument resembles nothing left of Byzantine work, and all French archæologists give them a date much more ancient.

Between the time of the Romans and the Byzantines there is nothing architectural to remark. Among the records, however, of this date in the museum are some of considerable interest. One gives as an epitaph an account of probably the earliest pilgrimage recorded, and which must have been a long one, as the pilgrim—a female—speaks of having visited all the cities of the whole earth on naked feet. Another made during the persecution in the reign of Diocletian gives an inventory of the sacred vessels and vestments appertaining to a Christian church.

Few of the great works of the Byzantines are left, though the marks of their connection with Africa are indelibly stamped on much of the work executed in later times.

At Tipasa are said to be the ruins of a large church now filled up by the huts of an Arab village, which, by an unfortunate accident, Professor Lewis was prevented from visiting, nor could he obtain any description of them. At Bon Ismail he found the ruins of an apparently very early church in a tolerably perfect state. The plan was a parallelogram about 143ft. by 43ft. clear of the walls. To the west were the remains of an arcade—(the narthex). At the east end is a large crypt consisting of an apse with a chamber on each side, now almost perfect, the whole built and vaulted in very good squared masonry. Remains of steps leading to the central crypt still exist, and in the centre of it is a singular excavation, somewhat in the form of a coffin in the solid rock, with steps cut in it at one end.

At Constantine are the scanty ruins of a church said to have been founded in the time of the emperor of that name, but the church may have been built over and over again since the time of its foundation.

The chief works of the Arabs, so far as Professor Lewis could personally speak of them, were in the town of Algiers. The whole town is comparatively modern, and dates from about the same period as that of the chief Renaissance architects of Italy (Michael Angelo 1474-1563; Palladio, 1518-1580; Sansovine died 1570; Scamozzi 1552 1616). The streets or thoroughfares are mere alleys winding about the side of the hill in paths so tortuous and irregular that a stranger has but one means of discovering his means of escape from them, viz., by persistently going down hill wherever they may lead, by which method he must of course find himself at the bottom of the Arab part, which is built on the side of a steep hill. The houses, mosques, and palaces, their domes and minarets, are white, having flat roofs with little or no gable and few and small windows. Of all its buildings one of the most ancient and interesting is the grand mosque the Djama Kebir. It stands close to the sea, a small part of the sea wall rising above the rest and marking the place of the sacred niche fronting Mecca. The plan is the usual one—a series of arcades surrounding an open court in which is a pretty fountain shaded by a mulberry tree. All the arches are of the same height—all avenues of the same width. There is no grand vault, no transept, nothing on plan or section or elevation, to show that the architect thought of bringing the edifice into one grand mass. Just outside the door of the mosque is a well-designed though simple building, in which the cadi's court is held. It is square on plan and covered with a dome, and has in front a little colonnade with marble benches, the whole forming as picturesque a composition as could well be found, outlines and details being graceful alike. All this is genuine Arabic, as the date would show, the mosque having been built in 1000 and the minaret in 1322. Close by is another mosque—that of the Fishery or the new mosque, Djama Djedid. This is markedly different throughout. It has no open court, its fountain is in the mosque itself, as our fonts are, and the whole edifice is designed as one complete building, with high nave, aisles of a lower height, spacious transepts, and a dome boldly carried on pendentives, whose graceful outlines please the eye even through the horrible daubings of paint with which the French have sought to please their Mahommedan subjects. These outlines are not Saracenic. Their history declares itself to the eye of the architect at once — viz., that they were designed by a Christian architect of Greek extraction, and whose recompense for the work, according to the stories—it was said untruly told of him, could scarcely have been countenanced by the Institute's scale of charges. For the accounts merely differ as to whether he was bowstrung or burnt to death, but agree as to the date—viz., the sixteenth century, under the Turks. He seems to have given the mere outlines only, and either to have had no workmen to whom he could entrust the execution of the usual Byzantine details, or to have trusted to being able to encrust the walls with the usual marble or mosaics, which, in this case, he never had. The pulpit and the mihrab, or sacred niche, however, show at once that if the masters were Greek the workmen were true Saracens ; for the ornamentation is as markedly their work as the design was his, and it would be difficult to find anything more delicate and graceful.

In walking through the streets in the Moorish quarter nothing is seen of the interior of the houses, and the narrowness of the streets allows little even of the exterior to be seen ; in the Jewish quarter, however, it is different. Of one of these houses Professor Lewis exhibited drawings. The exterior is of the plainest kind, with no regard to picturesque effect, symmetry, or proportion. With the entrance door begins one's sense that Moorish work is not to be judged of at first sight. A long corridor is entered, having on each side a wide marble bench, which serves as a stylibate to a row of white marble columns carrying arches of a very peculiar shape, but common enough in Algiers. The front of the bench is lined with coloured tiles, and the floor is of white marble or tiles, with which the walls at the back of the columns are also lined. In some houses the steps lead to an open court, in others to the staircase. The flights of stairs are arranged one over the other, but the soffits do not slant as with us, but are horizontal, and follow the raking line by succession of steps, which have an excellent effect. The treads are about 14in. wide, and the risers are of tiles, with which the walls are lined about 3ft. or 4ft. high. The soffits have open timbers resting on a small plain cornice. The stairs lead into an open courtyard, always square, surrounded by colonnades two stories high never less, but sometimes one or more extra stories—which then recede to the range of the walls, leaving an open terrace over the colonnade.

The whole work forms a singular mixture of styles. The central court is as much Italian as Moorish ; and the central doorway to each gallery, the little windows opening out of the small domes at the end of the colonnades, the railings to the front, and some minor details are Saracenic, and in many cases of exquisite beauty.

Nothing could be more beautifully designed or worked out than the small domes of the archbishop's palace or of that of the governor ; yet all the main doorways to the corridors and staircases throughout are Italian —of a very debased kind, yet clearly copied from a good example. But, curiously, every doorway throughout the town, no matter of what size or where, is of the same identical pattern, or so near it as to show that it was copied from the original. The columns are well nigh as curious—always of marble—and the capitals and mouldings boldly carved. None of them, as far as Professor Lewis could see, were antique, and few were copies from the antique. In the corridors they have spiral shafts, and in many instances on the colonnade. A peculiar form of capital is also to be met with all over the town. The same patterns of tiles are also seen everywhere, and these are recorded to have come from Leghorn, and to have been Italian. The design of the large window is equally curious with the other parts, as they are as invariably square as the doors are circular, and almost always have wide architraves with ornamental scroll work of the kind found in the archbishop's palace.

Fixing the date of the town at the end of the sixteenth century, when the Turks had possession, we can only imagine that among their captives they had some master mind as an architect ; that he gave the general outlines and sketched out the details of some of the buildings, which met with the Turk's intense approval, and that the details of the numerous others were worked out from his sketch by Saracenic, Byzantine, or Italian workmen. The facts, however, only [illegible] theory, as [illegible] and [illegible] met with.

The construction [illegible] enough. They were [illegible] very hard and much better than bricks [illegible] now, with mortar of a red kind of earth and [illegible]. In common [illegible] parts of the [illegible] were of [illegible] only, in the latter [illegible] were squared, and the [illegible] was [illegible]. The tiles used are of [illegible] peculiar [illegible]. They are of coarse earthenware of a light tint, which is covered with a very thick white. On this the pattern is painted, and then burned [illegible] by hand, and the whole [illegible].

Of modern Algiers little need be said. Though much has been done of late years there is little to interest the architect. Whether good or bad, the modern buildings are clearly French, and in carrying his architecture to a foreign land the Frenchman has gone on the right path, and will leave his mark to succeeding times, as the Turk, the Roman, and the [illegible] have done before him.

CRANBROOK CHURCH

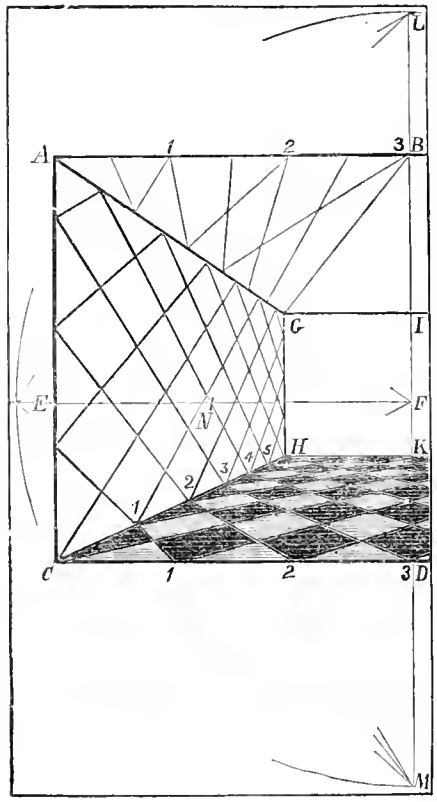
Cranbrook Church, Kent, called "the cathedral of the Weald of Kent," had suffered more than usual from the "modern churchwarden improvements." The magnificent roofs of its nave and aisles were utterly destroyed, a few pieces only being used again as ceiling joists. The ceilings were perfectly flat, and the ancient parapets were destroyed and modern ones placed in their stead. The dimensions of the church are as follows:—The nave is 110ft. long and 2[illegible]ft. wide, [illegible]ft. high to the plate. The whole width, including aisles, is 65ft. The arches are of the richest Third Pointed type, with beautifully clustered piers. Between each of the clerestory windows is a moulded shaft, supporting a sculptured angel, forming the corbel of the roof principal. The great range of aisle windows contains [illegible] Third Pointed work. The tower is of the usual Kentish type, low and massive. The chancel is early in date, and of poor proportions. Opening out of it, on each side, is a chantry of late date, with fine five-light windows. The restoration has been commenced, under Messrs. Slater and Carpenter, by the erection of a new nave roof and the restoration of the parapet stonework. This is now completed. The ancient fragments were carefully studied, and [illegible] remained to serve as guides for the new work. The pitch is low, and the [illegible] moulded tie-beams, the space between which and the principals is filled in with tracery. Under the tie-beams are arched braces, springing from the angel corbels, the [illegible] being [illegible] with rich carving. The [illegible] and [illegible] elaborately moulded, and are supported by curved braces springing from the king-posts of the principals, and supported on carved [illegible]. These introduce Henry VII. and his queen, and the Archbishop in whose reign the building was erected, as well as Queen Victoria and the late Archbishop, to serve as a date of its restoration. The next works that will be proceeded with are the aisle and chantry roofs, and then the [illegible]. The chancel was restored some few years ago by the Ecclesiastical Commissioners, and the oak chancel stalls and fittings were then erected. There is a curious baptistery in the church, a great square space enclosed by walls about 7ft. high, with stairs down into it from the top of the wall. As the bottom of this and the floor of the church are the same, the effect of this is somewhat remarkable. The works have been carried out by Mr. Jenner, and after his death by Mr. [illegible], resident clerk of works to Mr. A. J. B. Beresford Hope, M.P. [illegible] by Messrs. Pepper, of Brighton.

The new pigment [illegible] in some lead mines in New Jersey, U.S., in comparison with the other pigments in general use, is stated to [illegible] [illegible] great opacity [illegible] than [illegible]. It [illegible] oxide of zinc [illegible]. It [illegible] will wear much longer [illegible] weather [illegible]. It [illegible] greater [illegible] hydrogen and other [illegible] quickly discolour white lead. At the same time [illegible].

SCALES OF PERSPECTIVE DRAWINGS AND PHOTOGRAPHS.

THE application of photography to architectural subjects gives rise to inquiry concerning the scale of representations thus produced. Photographs are so frequently substituted for drawings made on the principle of perspective projection, which are known to have determinate proportions, that it may be useful to glance at the optical laws to which both the manual and mechanical methods are subject. The apparent size of any object depends on the angle at which rays from its extremities meet at the eye. The measure of this angle depends, in its turn, upon the actual size of the thing and its distance from the point of sight. The angle becomes less as the degree of removal increases, and a small object that is near may seem equal to a large one far off; but when the distance from the spectator and the angular measure of an object are known, the scale of a picture may be fixed if its position on the distance line be given, and the ratio of the two parts into which that distance is broken is ascertained—*i.e.*, as the distance between the eye and the picture is to that between the eye and the object, so is the size of the picture to that of the object. For the sake of familiar example let an observer standing at one foot from a window trace upon the glass the appearance of something ninety-six feet away from him. The representation will be reduced to one ninety-sixth of the real dimensions, or to the scale of an eighth of an inch to a foot, as very commonly used for architectural drawings. This proportion relates to things that come up to the face of the picture or are in contact with the plane of projection, and to which a scale of parts would be as applicable as to a geometrical elevation. But there is another order of proportion, or rather an extension of the same rule to receding parts of the picture; and these are measurable by an *échelle fuyante*. On this system the original distance (say ninety-six feet) is taken as one distance, and the size of objects on the edge of the picture as the standard of comparison. Then it is found that objects at two distances are only half the size of the first, at three distances only a third, and so on.

The accompanying diagram shows how the mathematical reasoning is brought to bear on the work of the draughtsman. A B C D indicate the section of one-half of a room on the plane of projection. F is the central vanishing point, from which a distance equal to that of the observer from the front of the object is set off horizontally at E. The horizontal lines at right angles to the face of the picture, as those of the wall A G and C H, run towards the centre F, and those which are parallel to the picture, as G I and H K, continue horizontal. The geometrical distances 1, 2, 3, &c., are set along the ground line C D, and lines drawn thence in the direction E, giving corresponding perspective measures along the wall C H. The plan of the room is a square equal to double the width C D. The back wall is, therefore, removed by twice C D and once E F from the place of the observer, together something under three times E F. The size of G H I K is consequently slightly larger than a third of A B C D. By fixing points L M above and below F, with the distance E, diagonal compartments on the vertical face of the wall A C G H may be delineated. The lines on the ceiling show the method of obtaining perspective lengths by half distances on the geometrical line, and drawing towards the point N midway between E and F. The accuracy is proved by another set of lines drawn in the direction E with the full dimensions 1, 2, 3, &c., on A B. No fixed proportion, however, is necessary. The architect in this way, by the aid of known dimensions, produces a perspective without recourse to a plan. Photography effects results of truthful representation utterly unapproachable by hand drawing, and it requires none of the subsidiary constructions, as the plans, sections, and elevations commonly necessary in linear perspective are sometimes called. It certainly appears too exacting to demand that photographic pictures should not only give perfect



similitudes, but the actual dimensions of objects. Still it is a point of great interest, and requires careful consideration. The artist ordinarily regards the human eye as a mere point, but it must now be examined more closely. It is an orb or globe of fluid contained in a tunicated skin of several coats. The open part (the iris and pupil) consists of a lens, through which the rays of vision pass to the inner coating at the back, called the retina, upon which the impression of outer objects is formed. There is this distinction of principle between a drawing and a photograph, viz., that the plane of a drawing is interposed between the eye and the scene, while the lens of the photographic camera comes between the scene and the picture. The camera operates, in fact, as a gigantic eye. The focusing distances of the lenses are always pretty accurately known, and the size of any object in the picture will be to that of the real objects as the ratio of focal length to the actual distance; but, according to the conditions already stated, under which pictorial proportion rests upon angular measures, it becomes obvious that the distance or the size of an object must be known before a scale can be decided.

TECHNICAL EDUCATION.

CONSEQUENT upon a conference held in the room belonging to the Society of Arts on the 14th of March last, under the presidency of the Earl of Lichfield, a "Workmen's Technical Education Committee" was formed for the promotion of the instruction of artisans in the practice of the respective crafts. The committee thus appointed have now published a report showing what steps have been already taken and what further proceedings should in their judgment be adopted. Their first step was to provide for the delivery of popular lectures, which had for their principal object to demonstrate how greatly the success of the national industry depends upon the progress of scientific discovery and the diffusion of scientific knowledge among all classes. Nine of these lectures were delivered during the months of May and June, at the London Mechanics' Institution, to small audiences, and reports of some of them appeared in our own columns. The scheme, however, did not escape the general drawback to most of such projects. It did not pay.

The committee have inquired carefully into the existing means of technical instruction in the metropolis, and their conclusion is that there is no adequate provision for scientific and detailed instruction available by working men at such hours and on such terms as would place it within their reach. They recommend, therefore, the establishment of science and art classes in the industrial quarters of London, and that the instruction at present afforded by the School of Mines and the School of Chemistry in the daytime should be also available at night, and in localities more convenient to the working man. The report further calls on the Government to establish or to aid in establishing a few great central schools for foremen and managers, similar to the Ecole des Arts et Métièrs of France, to which students may proceed by means of scholarships and exhibitions from the more elementary schools.

Reviewing at some length recent reports on the subject of technical education—viz., those issued by the sub-committee of the Society of Arts and the report of the Select Committee of the House of Commons—the report approves and confirms the former, but considers the latter to have failed in its purpose, and to have rendered it "more incumbent on this committee to pursue its work." The committee appeal to all classes to aid them in their effort to bring the cause they advocate before the public of this city, so that gradually—first in one district and then another—museum-schools may be set on foot. To working men they especially appeal for support in the task which they have undertaken, and the furtherance of which will necessarily involve some expenditure.

THE INSTITUTION OF CIVIL ENGINEERS.

THE annual general meeting of this institution took place on Tuesday evening last. From the report we find that the following papers were read and discussed during the last session:—The Irrigation in India, Spain, and other warm climates, and on the proper construction of Irrigating Canals; the Manufacture and Wear of Railway Bars; the relation of the Fresh-water Floods of Rivers to the areas and physical features of their basins; on Floods in the Nerbudda Valley, with remarks on Monsoon Floods in India generally; on the Victoria Pridge on the line of the Victoria Station and Pimlico Railway; on New Railways at Battersea, and the widening of the Victoria Bridge; the City Terminus Extension of the Charing Cross Railway, embracing a description of the Cannon-street Bridge and Station; the Durability of Materials; the Supporting Power of Piles, and on the Pneumatic Process of Sinking Iron Columns, as practised in America; and the Experimental Determination of the Strains on the Suspension Ties of a Bow-string Girder. Although the topics thus dealt with had been comparatively limited in number, yet it was believed they might be fairly regarded as representing some of the principal problems now engaging the attention of engineers.

The new building, with furniture, cost upwards of £17,000. There were on the books on the 30th of November last, 16 honorary members, 637 members, and 896 associates, making a total of 1,549, inclusive of students. The admissions to the class of students, which had only been in existence one session, had amounted to the same date to 133.

The following gentlemen were elected to fill the several offices on the council for the ensuing year:—Charles Hutton Gregory, president; Joseph Cubitt, Thomas Elliot Harrison, Thomas Hawksley, and Charles Vignoles, vice-presidents; James Abernethy, William Henry Barlow, John Frederick Bateman, Joseph William Bazalgette, Nathaniel Beardmore, Frederick Joseph Bramwell, James Brunlees, George Willoughby Hemans, John Murray, and George Robert Stephenson, members; and Major-General Sir W. T. Denison, K.C.B., and Frederick Ransome, associates.

On Thursday week Mr. Raphael Brandon read a paper at the Inventors' Institute, describing his scheme of reform for railways and reduction of fines, which was duly reviewed in our columns some time since.

THE HOLY SEPULCHRE.

LATE advices from Jerusalem describe the present state of the work of restoration and repair of the Holy Sepulchre, now so near completion. Our information is from a French and not a Russian quarter. The works, as is known, are carried out under a protocol signed at Constantinople by the Grand Vizier, again in office, Aali Pasha, and the ambassadors of France and Russia. One great political and religious difficulty consisted in this, that the Greeks or Orthodox, profiting by Sir Sidney Smith's exploits at Acre and the decline of French influence, not only took possession of the Lamp Gallery, but in 1808 reconstructed the great dome, painting it with Greek saints, some of whom had been opponents of the Roman see, and decorating it with Greek inscriptions. The Latins claimed that the dome should be brought back to an ancient state of Latinity. After political difficulties on this question, culminating in the Crimean war, it was shown that the dome was again in danger, and it was arranged to pull it down and rebuild it. So far as bricks and mortar were concerned there was no difficulty, but the religious ornamentation was an unappeasable contest between the rival ecclesiastics. After great delay the matter was settled by personal arrangements between the Emperor Napoleon and the Emperor Alexander, the Ottoman Porte acting as moderator. Messrs. Mauss and Eppinger have been the respective architects. From the commencement of this year the works have been pushed on with great rapidity, so that the completion has been announced. The new dome is rather higher than the old one, and shows much better in the view of the city. The cross was placed on the dome by the beginning of August, and was uncovered on the 15th, the saint's day of the Emperor Napoleon, when a kind of inauguration took place. The painting of the interior of the dome is completed, but at the last advices they were waiting for the railings of the gallery of lamps, which are supplied from Paris, and also the door of the gallery and the door of the dome.

THE GAIETY THEATRE.

THIS theatre, built on the site of the Strand "Musick" Hall, was opened on Monday evening last. There has recently been something like a rage for theatre building in the metropolis. During the last two or three years a theatre and an amphitheatre have been built in Holborn, also the Queen's in Long Acre. About a month since the Globe, in Newcastle-street, Strand, was opened, and about 100 or 150 yards from the same spot the Gaiety has sprung into existence. The Strand and two or three adjacent streets may be regarded as the theatrical head-quarters of the metropolis. Within about 200 yards of Exeter Hall, there are no less than nine theatres. Besides three we have mentioned there are the Adelphi, Covent Garden, Drury-lane, the Olympic, the Lyceum, and the Strand theatres. About ten or eleven o'clock at night all the streets are crowded with vehicles, from the Dowager's splendid carriage to the cab, all waiting to take home theatre-goers. If speculators will go on building theatres in the same neighbourhood as they have been doing recently, the streets will have to be widened for the accommodation of cabs and carriages.

The Gaiety Theatre just opened is a novelty. Not only is it a novelty, but it is an excellent move in an important direction. The old London theatres are, with hardly an exception, a standing disgrace to the age, and only one degree less dingy, stuffy, and uncomfortable than their brethren of the same age in Paris. Many of the new or partially new ones, too, are little better; but to these the Amphitheatre, the Queen's Theatre, and the new Gaiety stand out in honourable distinction. The opening of the youngest of the numerous family has been heralded with such a flourish of trumpets, and the theatre itself is in many respects so good, that it deserves more than the passing notice that buildings of its class usually receive, even from journals devoted, like our own, to constructional and artistic topics. As far as we can call to mind, the Gaiety is the first theatre in this country in which any attempt has been made to introduce the Gothic style of architecture; and we suppose that one reason that has induced Mr. Phipps to do so in this instance is that he had to appropriate some portions of the Strand Music Hall, which was Gothic with a vengeance. We may perhaps on a future occasion enter into the question of the applicability of Mediæval treatment to playhouses, but for the moment we are merely concerned with the new house as it stands. Its Gothic character internally consists chiefly in a series of blunt pointed arches above the gallery, in the clustered proscenium columns, and in a considerable proportion of the ornament. This however, is in itself a step forward, if only in the way of protest against the ever-recurring abuses of theatrical tradition. Another uncommon, though not absolutely novel feature in London, is the arrangement borrowed from the new French theatres of the projecting balcony with private boxes behind. This balcony is in itself perhaps one of the most pleasant inventions for those of the audience who frequent it, but it cannot be disguised that, in this instance at least, it has been introduced at a sacrifice of all considerations alike of comfort and convenience to frequenters of the pit. We attended both the first and second performances, and were careful to try the effects of sight in every part of the house. We found that from the pit nothing was to be seen but the performers and a very limited portion of the scenery; the same defect, though from another cause, manifested itself in the gallery. Of the pit only a limited portion of the first four benches is clear of the balcony, and the remainder is covered in by the balcony and the boxes so closely that a tall man with a hat on would find it somewhat difficult to stand upright. Another mistake in the pit, as we take it, is the lobby running all round it, whereby much valuable space is lost, and the draughts are unpleasantly intensified; nor can we believe that the wall separating the pit from the lobby is in itself a structural necessity. In the gallery, which is, by the requirements of the Gothic treatment of the house, raised to such a lofty elevation that the spectators obtain but a bird's-eye view of the performance, both sight and sound are materially affected by the arches alluded to. These may be in part a necessity. It has long been conceded that one of the greatest difficulties in theatre building has been to combine structural truth and strength with a large and open gallery. Of the boxes, balcony, orchestra stalls, and upper circle we can only say that they are commodious and well arranged. Still it should always be borne in mind that it is the pit and the gallery which make a house pay—a fact too habitually ignored by theatrical managers and architects.

We have seen several of Mr. Phipps' theatres, and on entering the Gaiety we were struck with the great difference between the general appearance of the new house and those with which we were previously familiar. The first impression is that of brilliancy, the second that of restlessness. Doubtless this is in some degree to be attributed to the style adopted; for Gothic, except in the hands of a master of its resources, is wanting in repose. But we find on examination that this hypothesis explains but little of what, as the evening advances, becomes more apparent. The more the eye wanders round the house, the more it passes from floor to ceiling and from ceiling to column, the more are we forced to the conclusion that there is something wrong in the treatment. Firstly, the admixture of raised and painted decoration has been anything but effected; secondly, there is an incongruous combination of details culled from the Gothic, Greek, and Egyptian styles; to say nothing of others less easy to define; and thirdly, there is a fundamental error in the treatment of the gold. Into these details we intend entering more fully next week, and we must for the present content ourselves with an expression of admiration of the thoroughly satisfactory way in which Mr. Marks has accomplished his task by no means easy. Instances of defects above the proscenium are admirable. Where the decoration has succeeded and where and why he has failed we shall endeavour to point out in a future article.

Our next number will also contain an illustration and plan of the new theatre.

RUBENS AND GOLD.

IN these papers I have been trying to show generally what it really is that in truth distinguishes old from modern art: that it is not merely a change in style of art and external circumstances, but a total change in the principles of art action and method of work, indeed, a complete reversal in the means whereby a work of art is produced. Some there are, it is to be hoped, who are beginning to see this, and the great fact that a work of art, whatever it is, cannot be produced by the present system of art manufacture, and that art is verily but another name for individuality of human action, that a man can no more be hired to paint a picture for another, or draw an outline for him, than he can write a letter or sign his name for him. Art is handwriting in material, whether in a picture, a building, or a painted tile. I admit this to be a hard saying, but the real question is, Is it a true one? The object of these notes is to prove that it is. Past art having, therefore, been what it was—viz., the result of individuality of artistic action, and the art so called of the present time being the very reverse of this, it becomes, if there be any truth whatever in the proposition, a matter of the deepest interest to single out the few things that are left to us from that past, and to study them with all attention. Example is always better than precept, and I would ask anyone to look at such buildings as St. Paul's Cathedral, before commented on, and the Temple Church, the roof of it particularly, the new additions and additions to Westminster Abbey, and at what is perhaps the best specimen of Italian or Renaissance architecture in England, the banquet-room, Whitehall, or, as it now is, the Chapel Royal. Of course it is well known to every reader of this journal that this fine room is but a part, and a very small part, of a complete royal palace, designed and planned by Inigo Jones for Charles I., and had it been completed by the architect it would have been beyond comparison the best and most magnificent building, as a whole in Europe; but the fates willed it otherwise, and its architect had to content himself with building and leaving this single room only as a specimen of what he could do. Perhaps, since the Gothic days, this has been the greatest loss that English art has experienced, and we must for ever lament the unfortunate circumstances that refused to so clever and original a genius [illegible] at Whitehall the opportunity which they afforded to Nash at Buckingham Palace, and to his modern successors on the same ground. But the history of art is full of these disasters and hindrances, so that we must content ourselves with the little we have, and try to make the most of it, and, above all, to keep and preserve it in the state it was left by its authors, or, when that has been all but destroyed by modern improvements, to at least advocate, if we cannot help, its true restoration. For the present, then, we may confine ourselves to the simple interior of this royal room or

TO CORRESPONDENTS.

TO OUR READERS.—We shall feel obliged to any of our readers who will favour us with brief notes of works contemplated or in progress in the provinces.

Letters relating to advertisements and the ordinary business of the Paper should be addressed to the EDITOR, 31, TAVISTOCK STREET, COVENT GARDEN, W.C.

Advertisements for the current week must reach the office before 5 o'clock p.m. on Thursday.

Correspondence.

THE GROTESQUE IN ART.

To the Editor of the BUILDING NEWS.

SIR,—Your correspondent Mr. Statham has so completely refuted the apologists for grotesque art that little need be added save that the majority of your readers must endorse his sentiments. The "grotesque" in art is both unfeeling and certainly not in harmony with the spirit either of an enlightened thought or Christianity. Indeed, is it not quite repugnant to the sentiments of the latter? Those who have considered the circumstances and conditions of religious thought under which the "grotesque" arose cannot for a moment entertain its admissibility in the present day, but must rather pity those who delight to design and carve the hideous and deformed—only fit embodiments of a religious terrorism. Things of the past are oftener valued more in the shade of obscurity than when brought out into strong relief by the strong light of the present; at least, those who expose them to it are their worst enemies.—I am, &c.,

G. HUSKISSON GUILLAUME.

HER MAJESTY'S THEATRE.

SIR,—Will you kindly permit us to explain to your correspondent of last week that the decorated box fronts from the old house which we exhibited at the *conversazione* of the Architectural Association were not those to which he evidently alludes in the body of his letter? As the explanatory label got mislaid on the occasion referred to, and as the articles attracted some curiosity, it may not be out of place to mention that in bringing forward the proscenium two years ago a length of each box front was removed. On removing the canvas with the existing decorations, various substrata of canvas, paper, paint, and distemper were found, and lastly a series of figure subjects, painted on gold grounds, and in very fair preservation. We cleaned them, and restored them only where materially damaged. We have been unable to ascertain anything definite respecting them, but they must be of considerable age—if not the original decorations. They appear as if painted in distemper, but wash like oil. Though they possess considerable power, and are altogether interesting, a similar treatment would be inapplicable at the present day. The surface canvases, however, which are similar in treatment to the remainder of the theatre at the time of its destruction, are still in existence (though very tender and greatly damaged). We need scarcely add that we shall be most happy to show them to anyone who may feel interested in the matter.—We are, &c.,

GREEN AND KING.

23, Baker-street, Portman-square, Dec. 21.

CONVENT OF ST. MARGARET, EAST GRINSTEAD.

SIR,—As the author of this design is reputed to be a thoughtful man and a good draughtsman, and as he is the chosen architect of what will perhaps be the most important building of modern times—the Law Courts—I turned to the view of St. Margaret's Convent with much interest, expecting to see evidence of ability of the highest order. I was greatly disappointed; and as I think a criticism of the design may benefit the younger portion of your readers, I have jotted down the particulars which chiefly struck me.

The centre apartment, called gateway (N), appears to be really a hall with a doorway at each end and a small window. The window appears to be not more than 6in. wide, and what is its use? If light was necessary why not a proper sized window? If not required for light, why any window at all? It will be seen in the perspective that its height from the ground is about 9ft., so that it can't be used to look out of. From this hall, to the right, is a passage about 50ft. long unlighted, except something be got from the staircase, which, however, appears to be enclosed. On the opposite side of the hall is another passage, in which for a length of more than 50ft., forming a right angle, there is no light. The darkness of these passages would, of course, be repeated on floors above. Attached to the last-named passage is what is called a court (Y), but which, as it is roofed and is lighted by a window, is really a room. From it is another dark passage leading to coal-cellars and water-closets, the latter having neither light nor external ventilation. Many of the apartments, I notice, have no fireplace. This is an especial hardship for the portress. A staircase is near a class-room, between internal walls without light. As a contrast to those parts deficient in light, the passage at end of kitchen has seven windows!

The refectory, which is nearly 70ft. long, has apparently only two windows—one in the gable, the other in a recess at side. The dais, which is at one end, though appropriate, and necessary in an old baronial hall, is not required, and ought not to be in a convent refectory—bad in principle and contrary to ancient usage.

Except the gable windows the chapel appears to be without light. The *grees* to altar table is a notable point. The reformers of the English Church directed that the officiating clergyman should stand on the side of the Communion table, and such until recently was the universal usage, but the ritualists prefer the Romish practice, and to compel refractory celebrants to do the same gave no standing room at the side of the table. The great number of steps now put to the communion table is at variance not only with Protestant custom but the ancient practice. It is one of those points in which ritualists out-Rome Rome herself.

As the coal cellar comes next to the scullery I should have expected to see a doorway leading from one to the other instead of this. To get from one side of the wall to the other the servant or sister will have to go a roundabout way in the open air. The "knives," too, I should have thought would be better opening from scullery.

In the perspective the roof of lean-to to the left is strangely out of drawing. The greater part of the drawing is shown finishing under the eaves of the higher roof, but the end, which looks as if meant to represent a hip, though the angle is wrong, runs up into the higher roof. This could not be in execution. The higher roof I refer to is high indeed. The perpendicular height of the roof I judge to be about 25ft.; the span is about 22ft. It may be noticed in this design the affectation of construction, putting relieving arches over one-light windows, mere squints, other three-light windows have no such arch. The high and small windows are surely not necessary to a religious house; they give the idea of gloom, secresy, and enforced seclusion. The drawing of perspective appears to me to be altogether wrong. The front is almost in elevation, and with any such view possible the sides of the buildings could not show to anything like the extent displayed in the view. The very conspicuous turret has no *locus* on the plan, though so essential to the perspective. The thing is simply fudged, it appears to me. A sort of inner doorway appears to principal entrance on the perspective, but nothing of the kind shows on the plan.—I am, &c.,

M.

Intercommunication.

NOTICE.—As several mistakes have recently been made in the figures and formulæ in "Intercommunication," correspondents are respectfully requested to write as legibly as possible, and to write on only one side of the paper. Questions should, if possible, have short generic names put to them, for the purpose of reference and indexing. Answers should always have the corresponding number and name of the questions prefixed to them.

QUESTIONS.

[1188.]—NEW COLLEGE AT BEDFORD.—Some time ago I saw in the BUILDING NEWS a design for a new college at Bedford. I should like to know if the same is built, and if so if any of your correspondents can give me any information about it.—C. P. E.

[1189.] CHARGING FOR MATERIALS.—Will any practical builder or builder's clerk please give me the subjoined information? After what principle does he money out or charge for his materials? Admitting that he charges less to the trade, does he go from a certain price list, either of his own or that of Skyring, Laxton, or other party? because I have seen bills made out by the same builder against different customers at as many different rates for the same sort of goods, and am at a loss to understand the why and wherefore, especially as the material supplied was under the same trouble. Is it proper to have an uniform rate and keep to one list and abate if necessary on payment? or is it legal to charge one man £5 and another £6 for precisely similar articles? A reply from an experienced gentleman will oblige.—R. C.

[1190.]—KEEPING BUILDERS' ACCOUNTS.—Will any kind friend in a builder's office help me out of a dilemma? I commenced keeping a builder's accounts at the beginning of this year, and have continued them till now on a principle differing greatly from their former fashion. Now the way in which they were previously kept was by a ledger, in which the materials and labour were entered from a board, but not priced out till the year's end; the bills were then made out against the customers at prices varying greatly. On the bill being paid it was settled in this ledger by two large black lines extending from corner to corner, and here the bookkeeping begun and ended. Of course no balance of cash, goods, stock, profit and loss, or any other balance was made, and the business is considerably more than this: not even accounts of goods bought were kept. My way of doing the thing is to keep a waste book containing all the matter of the day, both inwards and outwards, cash, and everything else, balancing the cash daily together with a separate bill book. From the day book I journalise and arrange for the ledger, in which no particulars are to be seen, but are referred to by folios. My ledger is double, and in it are debited and credited twice over all the journal entries; I make frequent trial balances, and from the nature of this double entry all my debits and all my credits equal each other. I propose at the year's end to make a final balance, close the ledger, and prove the books, of course showing the profit of the year's proceeds. This is all kept up regularly, and yet my friends say it is all nonsense, and that the old way is practical and quite right. Please, therefore, insert this for public opinion.—PARIS.

[1191.]—SECTIONS AND SCANTLINGS.—Perhaps some of your readers would kindly inform me what are the best sections and proper scantlings for wood and iron girders to carry the floor of a lecture hall 36ft. wide, girders to be 12ft. apart from centre to centre: headway is a consideration. H. C.

[1192.]—DAMPPROOF BRICK WALL.—Can any of your correspondents inform me if there is any really effectual method of making an ordinary uncemented 9in. external brick wall exposed to the south and west damp proof? Many preparations are advertised, but few of them are successful. I should be very glad if some of your readers could give me a preparation which they have proved to be effectual.—A SUBSCRIBER.

[1193.]—GLUE.—How can I prevent glue cracking as it does when very dry, thereby causing objects fastened together with it to fall asunder?—JOINER.

[1194.]—RESTORING OIL PAINTINGS.—Does varnishing injure oil paintings? I want to clean one or two, and have been advised to wash and varnish them. Can any subscriber advise a safer mode of proceeding?—LOUIS J.

[1195.]—HARD TRANSPARENT VARNISH.—Can anyone inform me if there is any varnish applicable to Stevens's wood stains, transparent, yet hard enough to protect the wood.—A STAINER.

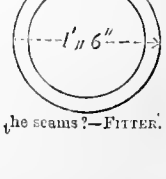
[1196.]—SOLIDIFYING MARBLE.—Can any reader of the BUILDING NEWS advise me as to the best method of solidifying marble after it has been pounded, or of incorporating a mixture of marbles of uneven qualities so as to form a substance that might be used as terra cotta?—ÆSCULAPIUS.

[1197.]—BRICK AND PIPE SEWERS IN LAND.—Will any of your professional readers kindly state their mode of constructing brick and pipe sewers in bog land reclaimed from the sea or otherwise? Having no solid foundation from 20ft. to 50ft. deep, what means were employed to procure a proper foundation, and if such means were effectual?—C. E.

[1198.]—EAVES RIGHTS.—The eaves of A.'s house project 6in. on B.'s ground, and has been exercised for 23 years. Has B. a right to remove the eaves of A.'s roof, or build a wall close to its wall and above the eaves? One surveyor states that A. has a right to the drip of his eaves. Another surveyor says B. has a right to build perpendicular from the extent of his ground at bottom. Will some one explain this difference of opinion, or refer me to some decision thereon? which will oblige—W. F. VARNEY.

[1199.]—ENGINE FOUNDATIONS.—I am getting in some foundations for a steam hammer, and have been informed that something must be put between the bedplate of the hammer and the concrete in order to form a kind of cushion to deaden the weight of the blow. Can any of your correspondents give me their own experience on the subject? An early reply will greatly oblige, as I have already got the concrete nearly up to the proper level.—A YOUNG CONTRACTOR.

[1200.]—STRENGTH OF IRON CYLINDERS.—I wish to ascertain the strength of a wrought-iron cylinder, of the dimensions shown in the figure, to resist steam pressure. The height of the cylinder is 4ft. 3in., and it is made of the best boiler plate. What would be the bursting pressure, and how would the cylinder fail? Would the ends be blown out, or the metal ripped open along the seams?—FITTER.



[1201.]—SCARFING TIMBER. — Would one of your subscribers to "Intercommunication" give me a sketch in your next number of the best way of scarfing two half balks of memel, 12in. by 6in.? They are intended to be used in supporting the floor of a warehouse; no support can be allowed nearer than 5ft. on each side of the joint.—A CONSTANT TAKER OF THE "BUILDING NEWS."

[1202.]—DERRICK CRANE.—I should be extremely grateful to anyone who would let me know what should be the scantlings of the post, jib, and tie of a derrick crane to lift up to one ton and a half. I have some good sound Dantzic timber, but cannot afford to buy oak for the purpose.—WHARFINGER.

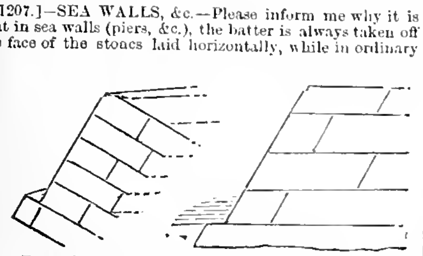
[1203.]—BROWN INK.—Can anyone recommend me a good rich brown ink, which will not fade? I used some about twelve months since described as indelible brown, but which, I think, ought to be called invisible, as lines which I then made with it, strong and dark, are now scarcely perceptible.—NEMO.

[1204.]—GILDING ON WOOD.—I shall be glad if some one can inform me of some description of gold that can be applied with the brush. I am acquainted with Bessemer's gold paint, which I do not like. I wish to have something that will be equal in effect to gilding with gold leaf.—AURE.

[1205.]—STEARINE.—Can any of your readers inform me of the best method of preserving plaster casts from soiling? I am aware that stearine is used for the purpose, but do not know how to apply it.—PLASTER.

[1206.]—FAMILY VAULTS.—Will some of your correspondents kindly inform me what is considered the best arrangement for a family vault for a cemetery or churchyard; and what is the best method of providing for interment therein? I presume the vault should be accessible by steps (ordinarily covered with a flag or landing), at the foot of which would be placed the vault proper, leaving a passage 3ft. wide, with the shelves on either side, say 2ft. 3in. wide, the length being about 7ft. I should be particularly obliged if some one of your experienced correspondents would kindly give me some hints on the matter, and oblige—A CONSTANT SUBSCRIBER.

[1207.]—SEA WALLS, &c.—Please inform me why it is that in sea walls (piers, &c.), the batter is always taken off the face of the stones laid horizontally, while in ordinary



Retaining Wall. Sea Wall.

retaining walls it is got by laying the bed of the stones at right angles to the line of batter on the face.—INQUIRER.

REPLIES.

[1080.]—RETAINING WALLS.—"X + Y" cannot have reduced the equations for rectangular walls given in my last communication, or he would have found that the thickness for stability is not twice that for equilibrium; for, in the equation for equilibrium $O = h\,w\,x \times \frac{x}{2}$, $x = \sqrt{\frac{2O}{h\,w}}$, and in that for stability $O = h\,w\,x \times \frac{x}{4}$ (or its equivalent $2O = h\,w\,x \times \frac{x}{2}$), $x = \sqrt{\frac{4O}{h\,w}}$. In the case of the wall with triangular section, his formulæ for D are correct. For equilibrium, $D = \sqrt{\frac{3O}{W\,H}}$; for stability, $D = \sqrt{\frac{6O}{W\,H}}$. The overturning force must be in all cases doubled for stability, and not the thickness of the wall.—J. L.

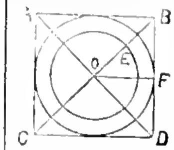
[1127.]—GUINEAS.—"E. P." is not quite right in his explanation of the legend on the reverse of George III.'s guineas. As it stands on the coin it is "M. B. F. et H. Rex F. D. B. et L. D. S. R. I. A. T. et E.;" this is meant to suggest "Magnæ Britanniæ, Franciæ, et Hiberniæ Rex; Fidei Defensor, Brvnsvicensis et Lunenburgensis Dvx; Sacri Romani Imperii Archithesavrarivs et Elector;" *i.e.* "(George D. G.) King of Great Britain, France, and Ireland; Defender of the Faith; Duke of Brunswick and Lunenburg; Arch-Treasurer of the Holy Roman Empire, and Elector." The crown of Charlemagne, which is on a small inescutcheon on the fourth quarter of the shield, is the symbol of the office of Arch-Treasurer of the Holy Roman Empire. Obscure as abbreviations often are, I think the height of obscurity has been reached by this ridiculous legend.—J. H. M.

[1129.]—TRIANGLES.—"W. J. C.," in yours of the 18th, tells us that the sign ° is used in land surveying to express links. I beg to say it is no such thing, and that links are always written down by themselves in whole numbers. The sign °, in the surveyor's field book, is, I think, sometimes used to denote stations on the survey, the crossings, intersections, and meetings of lines, and so also the accompanying signs.

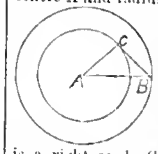
+ . T . × . S . ⊙ .

Besides, "R. F." himself says that he meant feet.—ROBERT CARPENTER, Great Marlow.

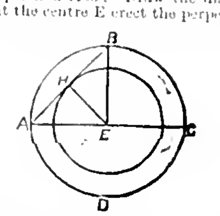
[1163.]—AREAS OF CIRCLES.—Your correspondent "C. E. O." may find the radius of the smaller or inner circle that he requires as follows:—Draw the square A B C D circumscribing the outer circle and the diagonals A D, B C intersecting at the centre O. Bisect O B at E, and O E will be the radius required. The demonstration is this: Draw O F parallel to A B or C D, and bisecting B D at F. Now as the areas of circles are as the areas of their circumscribing squares, that is, as the squares of their diameters, and O B equal to twice O E, is the diameter of the inner circle, the area of the outer circle is to the area of the inner circle as the square of B D is to the square of O B; but the square of B D is equal to four times the square of B F, or of its equal O F, and the square of O B is equal to the sum of the squares of O F and B F, or to twice the square of B F; therefore the square of B D is equal to twice the square of O B, and the area of the outer circle is consequently equal to twice the area of the inner circle.—JOS. S. DAVIES, Leeds.



[1163.]—On A B, the radius of the outer circle, describe the right-angled triangle A C B, having the sides A C, C B, which subtend the right angle, equal to each other. With centre A and radius A C describe the inner circle. Then shall the area of the space between the circles be equal to the area of the inner circle, and they shall each of them be equal to half the area of the outer circle. Let A B = r, and A C = r_1; then area of outer circle = πr^2, and area of inner circle = πr_1^2. Therefore, the area of space between the circles = $\pi (r^2 - r_1^2)$. Because A C B is a right angle $CB^2 = AB^2 - AC^2 = r^2 - r_1^2$, therefore $\pi\,CB^2 = \pi (r^2 - r_1^2)$, that is to say, the area of the space in question is equal to a circle whose radius is the length of the line B C, and is also equal to the area of the inner circle, for by construction A C = B C. But these two equal areas are together equal to the area of the outer circle, therefore they are each equal to half its area.—PURLIN.



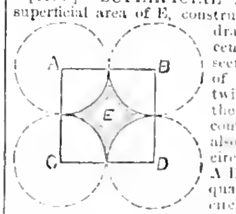
[1163.]—I think the following demonstrates what "C. E. O." requires in question 1163:—Draw the diameter A E C of the circle; at the centre E erect the perpendicular E B;



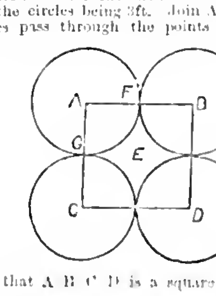
join B A, and bisect it in H; join H E, which will be the radius of the inner circle. This I can prove, if required.—C. P. E.

[Answers to this question have also been received from "J. T.," "Jack-plane," "F. C.," "Henry Carter," "Jos. A. Davis, Leeds," "Nix," "J. Battye, 25, Brazenose-street, Manchester," "A. S., Lincoln."—ED. B. N.]

[1165.]—SUPERFICIAL MEASUREMENT.—To find superficial area of E, construct the square A B D C by drawing lines from centre to centre of each circle. It will be seen that the length of any side of the inscribed square, being twice the radius of any one of the given circles, will equal the common diameter of the circles; also that four quadrants of the circles are inscribed in the square A B D C; but the area of four quadrants equal the area of one circle; therefore, the area of the square A B D C, less the area of one circle, equals the area of E. The area of a circle is obtained by multiplying the square of the diameter by .7854; hence we have—6^2ft. — (6^2ft. × .7854) = 7.736ft. = area of E, when the common diameter of the circles is 6ft. Again—3.5^2in. — (3.5^2in. × .7854) = 2.63in. = the area of E, when the common diameter of the circles is 3½in.—HERBERT PETTIFER, Soho Hill, Birmingham.



[1165.]—Let A B C D be the centres of four equal circles. It is required to find the area of the quatrefoil E, the radius of the circles being 3ft. Join A B, A C, C D, D B. These lines pass through the points of contact of the



circles, so that A B C D is a square; and A F G is a quadrant.

$$\therefore \text{Area of E} = A\,B\,C\,D - \frac{\pi r^2}{2}$$

$$= 36 - 14.1372$$

$$= 21.8628\text{ft. approximately.—H. C. B.}$$

[1165.]—Multiply the square of the diameter by 0.2146. The area of E is clearly equal to the area of the square A B C D, minus the area of the circle, or E = $d^2 - d^2 \times .7854 = d^2 \times (1 - .7854) = d^2 \times 0.2146$.—J. A. D.

[Answers have also been received from "D., Weymouth," "Jos. A. Davis, Leeds," "J. T.," "H. C. B.," "Nix," "A. S., Lincoln."—ED. B. N.]

[1166.]—TEST FOR PORTLAND CEMENT.—Road washed grit being the compound to mix with best Portland cement, one sixth of the last named for blocks, one fourth for paving, and thoroughly set, it is combined for testing in any shape.—JAMES SAXBY.

[1167.]—PAINTING ZINC.—Let "Village Builder" try the following. I met with it somewhere a short time back, and find it answer. Dissolve 1 part of chloride of copper, 1 of nitrate of copper, and 1 of sal-ammoniac in 64 parts of water, and then add 1 part of commercial [illegible] acid. Brush the zinc over with this wash; it gives it a deep black; leave to dry twenty-four hours, and any oil colour will then firmly adhere to it, and withstand both heat and damp.—K.

[1169.]—CHIMNEY POTS.—[illegible] chimney pots [illegible] washed [illegible] cement, is the thing. [illegible] broom or [illegible].—JAS. [illegible].

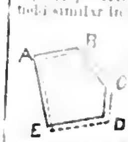
[1172.]—INDIAN INK.—[illegible] a small quantity of ox-gall with his ink or colours it will lay evenly.—G. H.

[1174.]—HOUSE CISTERNS.—[illegible] containing from [illegible] gallons would be sufficient for all purposes. As a cubic foot of water contains [illegible] gallons, the cubical contents of the cistern [illegible] would be sufficient.—R. I. B.

[1174.]—"Henry Carter" [illegible] head for each man, woman, and child, and [illegible] room for three days' supply [illegible] number of heads [illegible] by the number of gallons per head (15), we obtain [illegible] which, multiplied by [illegible] gives 900, the number of gallons the cistern will have to contain. Now the dimensions of the cistern must be ruled somewhat by the position it will have to occupy; but, assuming the space to be unlimited, we may put it at (say) 6ft. long by 5ft. broad, and 4ft. deep, giving 120 cubic feet; this multiplied by 6.250 the number of gallons contained in a cubic foot nearly, gives [illegible] the number of gallons which a cistern of the above dimensions will hold, thus allowing [illegible] gallons for an emergency. With regard to the second cistern for rain water, I do not see the need of it if the first is to meet all requirements [illegible] absolutely necessary to collect the rainfall, I think an underground brick cemented tank would be better adapted for that purpose, but to determine the size of which the area of roofs, &c., would have to be taken into consideration.—HENRY HOPKINS, Banbury.

[1174.]—Sufficient data are not given in this question to enable a [illegible] answer to be given, but a tentative answer may be given in such a manner that if it does not meet the requirements exactly the exact answer can be deduced from it by the questioner himself by varying the assumed conditions. It is assumed then, in this reply, that the water supply from the public service is a daily one. It is assumed also that the rainwater to be caught and used is that only which falls upon the roofs of buildings, and that that area is, in this case, about [illegible] square feet, being about four times the area of an average house, as the population (20 persons) is four times that of an average house, which has 5 persons, or thereabouts, taking big and little. Further, in the absence of a specified depth of rainfall per annum, taking an average of a series of years that depth is assumed to be, in this case, [illegible]. Now the quantity of water consumed for household purposes is from [illegible] to [illegible] gallons a day for each man, woman, and child of the population. If the rainwater be stored for use, the quantity required from the public service will be diminished by the quantity of rainwater that can be used, and this will be, where the annual rainfall is [illegible], and the surface upon which it falls is [illegible] square feet, [illegible] gallons a day, or from [illegible] to 4 gallons per head of the population per day. This is allowing nothing for loss by evaporation or absorption, which, indeed, is very small on such surfaces as house roofs. The quantity, then, to be stored in the cistern of the public service water (and therefore the size of the cistern) is for 20 inhabitants, from [illegible] to [illegible] gallons, taking [illegible] gallons per head per day, being the total quantity [illegible]. This would be contained in a cistern of, say, [illegible]. To arrive at the size of the rainwater cistern it is necessary to proceed on other data [illegible], however, we may [illegible] theoretically that it will be better to proceed on the basis of the practical experience in large waterworks' reservoirs, &c., although the circumstances of the two cases are not the same, there is sufficient analogy between them to warrant the preference of this mode of calculation to that of theoretical inquiry. The practical experience, then, in waterworks reservoirs, is that nothing less than a capacity of 20,000 cubic feet per acre of gathering ground is sufficient to retain the rainfall for use. In various parts of England this capacity varies with the amount of rainfall and the nature of the surface upon which it falls, but for present purposes it will be near enough to take it as stated. If, then, the size of the rainwater cistern be calculated on these data it will be found to amount to [illegible] cubic feet at the least; but as we cannot pretend to be very exact in such calculations as these it will be enough to say that the rainwater cistern in question ought to contain [illegible] cubic feet.—W. W.

[1177.]—HEDGES AND DITCHES.—In measuring a field similar in shape to the annexed diagram A B C D E, I [illegible] "Nix" that the fence [illegible] should be included in the quantity [illegible] when the ditch [illegible] [illegible] fence, as from A to B and A to [illegible] portion of the field [illegible] the remainder from B to D [illegible] property [illegible] the distance [illegible] [illegible] for the ditch.—H. H. H., Liverpool.



[1178.]—DAMP LIME OF FLOORING.—[illegible] rubble with [illegible] dust [illegible] with washed road grit and Portland cement [illegible].

[1181.]—PAVING STREETS.—In answer to "[illegible]," I may say that in laying pavements and particularly roads there is considerable economy when the joints are adapted only as allotted to the [illegible] [illegible] joints between each row of stones a course of [illegible] which has been brought to the same level to [illegible] the same extent as depth of the stones themselves. This plan, however, is not frequently adopted, though it cannot be denied that it affords a stay for the horse's foot by the formation of a series of small grooves about 1in. in thick-

ness and depth. This method has been adopted in Tooley-street, Southwark. The other and more frequently

FIG. 1. FIG. 2

adopted method consists in merely placing the paving stones in a canted position in their beds, as shown in Fig. 2. This method forms a series of ledges, or steps, which secures a good foothold.—A MAN IN THE STREETS.

[1186.]—THE BOARD OF WORKS AND NUISANCES.—I suppsoe "F. E." could make anyone pay for vexatiously interfering. He will, however probably find the inspector in the right; at least, such was the case with me a short time back.—B.

WATER SUPPLY AND SANITARY MATTERS.

FILTER-VANS FOR INDIA.—The *Lancet* speaks in favourable terms of a new invention for supplying troops on the march in India with good water. The Commander in-Chief recently inspected the vehicles, which are light, compact, easy of draught, and filled by means of a pump and hose near the driver's seat. The water is drawn off for use after passing through the filtering apparatus. Each van is capable of conveying and filtering 1,000 gallons of water per diem. Messrs. E. H Bayley and Co., of Newington Causeway, are the manufacturers.

LAND AND BUILDING SOCIETIES.

THE annual general meetiog of the members of the Guardian Permanent Building Society was held at Bristol on Thursday week, under the presidency of Mr. Jas. Derham, chairman of the board of directors. From the directors' report for the past year it appears that the total cash receipts amount to £19,436, as against £17,127 11s. 7d in the preceding year, and £15,582 15s. 2d. in the year 1866. During the year the directors have had the accounts of the society for the triennial period ending October 31, 1867, carefully investigated. After making due provision for future expenses in respect of existing shares, the net profit realised during the three years amounts to £1,172 11s; and the large sum of £841 6s. 9d. has been appropriated for distribution among the shareholders of all classes in accordance with rule 81. The residue, amounting to £281 4s 3d., has been added to the guarantee fund formed in 1865, which now amounts to £368 19s. 3d.; and during the seven years of the society's existence no loss whatever has been sustained, and consequently the guarantee fund remains intact.

STAINED GLASS.

THROUGH the munificence of a lady residing in New Brighton a handsome stained glass window, or rather set of four windows, has recently been placed in St. James's Church, New Brighton. They together represent the Ascension of Christ; the artist being Mr. Camm, of Smethwick, near Birmingham.

A stained glass window has been erected in the east end of the chancel of St. Thomas's Church, Batley. The window is in plan of the Decorated period, consisting of five principal compartments, and a magnificent wheel tracery has been filled with rich stained glass by Messrs. O'Connor, of Berners street, London. The artists have taken one idea as the motive of design for the whole window, viz., "The Love of Children," as shown in our Lord's teaching. In the principal part of the centre light is a life-size representation of the "Good Shepherd" leading into the fold a stray sheep. He holds the wicket open, looking down with benignity on the sheep whom he is specially tending, and whom the other sheep are hastening to welcome. The ground is strewn with flowers, and the evening sky is lighted up with stars. The picture is enshrined in a frame composed of the vine fruit and foliage which also encloses a most richly designed quatrefoil at the base composed of a lily worked into a cross. In the upper part of the same compartment is also a richly jewelled mosaic cross within a vesica. In the two compartments on the dexter side of this is a very large and bold group representing the Nativity and the visit of the worshipping Magi or wise men. In the two compartments on the sinister side the group represented is that of little children brought to our Lord. Both these groups are surmounted by very rich mosaic shrine work founded upon ancient examples in Westminster Abbey. The grand tracery is filled with a treatment of our Lord in glory, and St. Peter and St. Paul and a host of angels with musical instruments and palm branches, &c. The window has been presented by Mr. Sheard, the architect of the church, in memory of his daughter.

LEGAL INTELLIGENCE.

WORKMEN'S TIME.—A case of considerable interest, though only involving a small sum (1s 2d), was brought before Mr. Blanshard, in the North Shields County Court, on the 17th inst. A joiner, named Lumsdon, summoned Mr. Addison Potter, of Willington Quay, for the recovery of the sum mentioned; and as solicitors were employed on each side - Mr. Wheldon for the plaintiff, and Mr. H. A. Adamson for the defence—it was the principle rather than the value of the money involved that was contested. It was this:—The plaintiff, with some other men, had been engaged in out door joiner work in Mr. Potter's factory, and a day's work in such circumstances is from daylight to dark. Mr. Potter has a workshop where joiner work goes on before daylight and after dark by gas, or from six to six. The plaintiff, with some other men, had been working in the open air; but between two and three o'clock in the afternoon the material necessary to keep them employed ran short, and the foreman of the joiners told the plaintiff he must go into the work-shop and get some doors ready. He went, but at dark he knocked off. Next morning he returned, but there was no employment for him, and he had to go home. He summoned Mr. Potter for the quarter day he lost. The judge maintained that he was entitled to it. It was quite clear that the plaintiff was employed upon a definite class of work, viz., in the open air, the time for which was from daybreak to dark; and the defendant having failed to keep him supplied with material, it did not entitle him to order him into the workshop to get ready material that should have been got ready for him, except in the time for which he had been working previously. He gave judgment for the plaintiff with costs, and his day's pay as a witness.

WELL SINKING.—JAMES CHATTERTON *v.* WILLIAM GODDARD.—In this case, tried before the Cheadale County Court, £3 6s. was claimed, the balance of an account for well sinking. Mr. C. J. Blagg was for the plaintiff, and Mr. Bagshaw for the defendant. The plaintiff is a well sinker, residing near Froghall, and the defendant is a sub-contractor on the work now in progress connected with the building of the new college at Denstone. The plaintiff was employed at Denstone by the defendant in July last to sink a well, a portion of the sides of which gave way after the sinking had proceeded a certain depth, on which the defendant refused to pay the plaintiff the balance now sued for. The chief question involved was whether the falling in arose from the plaintiff's fault in not properly curbing (*i.e.*, supporting by circular wooden frames) the sides of the well as the sinking progressed, or whether it arose from the defendant's neglect in not duly providing the necessary curbs as they were wanted After listening to a great deal of evidence on either side of a technical character, his Honour gave judgment for the defendant.

THE VALUE OF WRITTEN CONTRACTS.—At the Clerkenwell County Court on Wednesday week, the case of Trattles *v.* Barnett was heard. This was an action brought by a joiner to recover £20 13s. 9d from James Barrett, of St. John's Park, Upper Holloway. The defendant, a speculating builder, had employed plaintiff on several occasions to make staircases. In January last he employed plaintiff to put staircases into two houses, and payment for these gave rise to the dispute. Plaintiff said the defendant had agreed to pay the measurement value for the work, which was £62, while defendant alleged that there was a verbal contract between them that the whole work should come to £45, which he had paid. The £45 was paid by instalments, and receipts were put in to show that it was the custom of defendant to pay the money by instalments as the work progressed Plaintiff, who contradicted himself continually on cross examination, admitted that verbal contracts had existed in respect to other jobs, but denied that there was any contract in this case. Defendant, on being put into the box, said that there was a verbal contract, and stated that he never gave a man a job in his life without fixing a price, although he seldom made written contracts. His Honour gave judgment for the defendant, believing that there was a verbal contract, but he refused costs, as defendant, by making a written contract, might have saved all the expense and trouble that had accrued from this action. Defendant's counsel here urged that the objection to written contracts was, that they had to be stamped. His Honour said the cost of the stamp would have been sixpence, and as the defendant thought to be economical, he must take the consequences.

Our Office Table.

A fine arts exhibition is to take place at Munich during next year.

Sir Charles Eastlake's art library, one of the best in existence, has been purchased for the National Gallery, where it is intended to form a reading-room, in the place of the Royal Academy Library.

Mr. E. J. Tarver writes to us to say that he is not one of the new sub-committee of the Architectural Association for the improvement of professional education, as stated by us last week.

It is stated by the *Athenæum* that Mr. Digby Wyatt is shortly to receive the honour of knighthood.

The situation of gas examiner to the Corporation of Loudon is vacant. The salary is £500 per annum. Testimouials aud applications are to be forwarded on or before January 4, 1869.

The trustees of the new chapel to be built at Melbourne, Derbyshire, met on Monday last, and after much patient consideration decided upon selecting the designs of Messrs. Wilson and Willcox, of Bath, architects. The competition was advertised lately in the BUILDING NEWS, and no fewer than eighty competitors entered the lists.

The railway whistle, says the *Levant Herald*, is at length to be heard in Persia. A combination of English capitalists has received from the Shah a concession giving them, for twenty years, the exclusive right to construct railways in the country; and last week Mr. Salomans, an agent of the concessionaires, passed through Pera on his way to Teheran, to break ground at once with a short six-mile line from the capital to the suburban village of Rey (Shah Abd-ul-Azui), a famous weekly resort of pious Tehcranlees. The ground has already been surveyed, and the report of the engineer employed estimates that the line may be constructed and stocked for a sum considerably under £100,000, on which the passenger traffic of some 40,000 devotees a week will, he reckons, yield a remunerative dividend—exclusively of an 8 per cent. guarantee.

The Sussex memorial to Cobden has just been completed. It is situated near Midhurst, and takes the form of a plain obelisk of sandstone rock, 34ft. in height. In plain bold letters, cut in on one side of the obelisk, is the simple inscription "Richard Cobden." Mr. Grist, of Midhurst, executed the work.

On Wednesday week the usual fortuightly meeting of the Edinburgh Architectural Association was held in the rooms, 5, St. Andrew-square, Mr. A. Ballantine, president, in the chair, when, after several new members had been elected, the second paper on "The Merits, Beauties, and Characteristics of Grecian and Mediæval Art," was read by F. G. Sumichrast-Roussy. The essay was confined to a treatment of the orders developed by the Grecians, which the lecturer showed were derived from the architecture of Nineveh and Egypt, and that the Greeks superadded to the architecture of those nations the elements of beauty, and that their art was characterised by intellectuality and refinement. A hearty vote of thanks to Mr. Roussy closed the proceedings.

Several new railways, which will greatly facilitate metropolitan travelling, are on the point of being opened. To-day (Christmas-day) that portion of the Metropolitan District Railway extending from Brompton to Westminster Bridge will be opened. There are stations at St. James's Park, Victoria, and Sloane-square. The trains will run "through" from Westminster to Moorgate-street, thus giving direct access to Kensington, Bayswater, Baker-street, and all the stations on the Metropolitan line. On the 1st of January a new line is to be opened to Kew and Richmond. This line is an extension of the Hammersmith and City line, which latter (an extension of the Metropolitan line) has long been opened. By this new line direct communication will be opened up between Richmond, Kew, the West End, and the City. On the same date the long-neglected facilities offered by the Charing Cross line for taking South-Western traffic into the City at Cannon-street will (partially, at any rate) be utilised.

From Cairo a private letter brings tidings that the viceregal capital is in the course of Haussmannic transformation. Squares, gardens, and boulevards are being cut in all directions, and the picturesque narrow and winding streets which have for centuries delighted the eye of the artist will presently be only seen in their works or in photographic reproductions. There is to be a grand Square of Roumelia, of which the principal ornaments will be the Saracenic mosques, now in course of repair. The bazaars have as yet been spared; but if during the visit his Highness paid last year to the Exhibition Baron Haussman imparted any portion of his spirit of demolition, these Oriental characteristics of the ancient city of the Mamelukes will speedily be made even with the ground, and in their stead a row of modern houses, with all the newest improvements, erected, of which the basement stories will be occupied by *marchands de nouveutes* and photograph vendors.

We have to record the death of the Rev. John Lewis Petit, B.A., the well-known archæologist and artist. He was born at the commencement of the present century, and was nephew of Louis Hayes Petit, M.P. Studying at Trinity College, Cambridge, he took his B.A. degree in 1823. He was a frequent contributor of papers on architecture and archæology to various journals, and at the time of his death was engaged upon an illustrated description of Howden Church. Amongst his published works we may mention "Illustrations of Church Architecture," in 1841; "Remarks on Architectural Character, and on the Principles of Gothic Architecture as applied to ordinary Parish Churches," in 1846; "A Description of the Abbey Church, Tewkesbury," in 1848; "Lectures on Architectural Principles," and "Lectures on Architectural Studies," in 1854.

The *Tablet* states that Mr. Henry Parker, the president of the Anglo-Roman Antiquarian Society, has returned to Rome, and the sittings of the members will be resumed, as well as the antiquarian excursions, as the weather and lengthening days admit of them. The accord that exists between this and the Roman Archæological Society, presided over by the Cavaliere Rossi, has been attended by the best results, and the entire plan of ancient Rome, regal, consular, and imperial, is being gradually subjected to searching discussion, and will, it may be hoped, form the subject of a permanent work in the English language, at a price accessible to all. To students of ancient art this would be a great desideratum.

Several improvements have recently been effected at the Crystal Palace. The strong draught caused by cold air streaming up between the boards no longer exists. The whole of the basement has been divided by numerous walls, and extra heating furnaces have been provided, while under the central transept 5,000ft. of additional hot-water pipes have been laid down.

According to a correspondent of the *Westminster Gazette*, considerable dissatisfaction exists among the Catholic laity respecting the appointment of Mr. Clutton as architect of the new cathedral in Westminster. It is contended that so important a work should have been competed for by the best men in the profession; for not merely competency, but talents of a very high order, should have been called into requisition. It is but fair to add that the rumour is contradicted in other quarters.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY.—Royal Institution, Albemarle street.—The first of a course of six lectures on "The Chemical changes of Carbon," by W. Odling, M.B., F.R.S.

THURSDAY.—Royal Institution, Albemarle street.—The second lecture on "Chemical Changes of Carbon," by W. Odling, M.B., F.R.S.

Trade News.

TENDERS.

ACTON.—Drainage Contract, No. 5, for Acton Local Board. Mr. E. Monson, C.E., Surveyor to the Board. Quantities by Mr. D. W. Young:—

Brunsdon	£695
Wigmore	669
Messrs. Blick	660
J. and S. Williams	645
Thackrah	630
Crockett	625
Towell	595
Adamson and Sons	595
Bloomfield	590
Young	575
Nicholson	532
Parker	529
James Pizzey (accepted)	525

DENBIGH.—For completing a covered reservoir and filter beds, for Denbigh Waterworks, at Love-lane, Denbigh. Charles H. Beloe, Esq., C.E., 22, Lord street, Liverpool. Quantities supplied by Mr. G. Shakeshaft:—

	Reservoir.	Gates, &c.
Thomas Stone	£850 0 0	£14 15
Fawkes and Mand	798 15 0	13 16
Dixon and Sleight	720 0 0	15 0
Clark	666 0 0	13 7
M'Lellan and Co.	663 0 0	20 0
J. Chester	647 0 0	18 10
Fogg and Co.	638 1 6	33 8
G. Stead	627 0 0	22 10
Evan Evans	600 0 0	29 0

HAYWARD'S HEATH.—For erecting a house at Hayward's Heath, for Fredk. Willard, Esq., of Brighton. Goulty and Gibbins, architects:—

Arthur R. Parr	£836

LONDON.—For the extension of the female chronic wards at the St. Marylebone Workhouse, for the guardians of the poor of the parish of St. Marylebone. Mr. H. Saxon Snell, architect:—

Thomas and Son	£5097	Colls and Sons	£4378
Jay	4809	Ball and Russell	4322
Temple and Forster	4775	Brown	4300
Turrell	4738	Simpson	4299
Johnson	4719	Turner	3997
Wigmore	4600	Scrivener and White	3987
Myers and Son	4567	Till	3984
Kirke	4496	Manley and Rogers	3884
Blackmore and Mally	4488	Baker and Constable	3.00
Bennett	4480	Foale	3670
Cooper and Cullum	4450	Crabb and Vaughan	
Ebbs	4387	(accepted)	3649

PULBOROUGH.—For alterations and additions to the Corn Exchange, Pulborough, for Messrs E. Robins and Son, of Brighton. Goulty and Gibbins, architects:—

J. and C. Whitcomb	£468
Iron roof for do—	
Morewood and Co.	124

COMPETITIONS.

SOUTH METROPOLITAN SCHOOLS, SUTTON (Surrey).—February 2.—For designs for the erection of an infant establishment adjoining the present schools. Premiums of 40 guineas each for the three designs considered the best. J. Burgess, clerk to the managers, Vestry Hall, Walworth.

ROTHERHAM.—March 15.—For plans for the erection of a public hospital and dispensary. Premiums of £75, £50, and £25. J. Barras, honorary secretary.

CONTRACTS OPEN FOR BUILDING ESTIMATES.

LITCHURCH LOCAL BOARD OF HEALTH.—January 18.—For the execution of certain drainage works in this district. W. Whiston, jun., clerk to the board.

RADNOR COUNTY GAOL.—January 7.—For alterations to this gaol. R. Banks, clerk of the peace, Kingston, Radnorshire.

MADRID (Spain).—January 20.—For the construction of tow markets. E. Petano, Chargé d'Affaires, Spanish Legation, London.

DERBY.—January 7.—For the erection of the new hotel and shops in the corn market. W. C. Watson, Derby Improvement Company's Offices, Wardwick, Derby.

METROPOLITAN BOARD OF WORKS.—January 8.—For the construction and maintaining in repair for twelve months of a brick and iron sewer in Deptford and Rotherhithe. J. Pollard, clerk, Spring gardens.

CALNE (Wilts).—December 31.—For the erection of a detached villa at Bremhill, near Calne. John Watson, architect and surveyor.

NORTHAMPTON IMPROVEMENT COMMISSIONERS.—January 6.—For the construction of a culvert in Herbert street. A. B. Markham, clerk to the Commissioners, 2, Derngate, Northampton.

BREAKFAST.—A SUCCESSFUL EXPERIMENT.—The *Civil Service Gazette* has the following:—"There are very few simple articles of food which can boast so many valuable and important dietary properties as cocoa. While acting on the nerves as a gentle stimulant it provides the body with some of the purest elements of nutrition, and at the same time corrects and invigorates the action of the digestive organs. These beneficial effects depend in a great measure upon the manner of its preparation, but of late years such close attention has been given to the growth and treatment of cocoa that there is no difficulty in securing it with every useful quality fully developed. The singular success which Mr. Epps attained by his homœopathic preparation of cocoa has never been surpassed by any experimentalist. Far and wide the reputation of Epps's Cocoa has spread by the simple force of its own extraordinary merits. Medical men of all shades of opinion have agreed in recommending it as the safest and most beneficial article of diet for persons of weak constitutions. This superiority of a particular mode of preparation over all others is a remarkable proof of the great results to be obtained from little causes. By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected cocoa, Mr. Epps has provided our breakfast tables with a delicately flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating round us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."
